This case is most unusual in that the pain in the hip was so severe and the limitation of motion was so annoying that several competent orthopedists had advised fusion for relief of symptoms. The x-ray revealed complete obliteration of the joint space. Relief from pain, increased muscle power and range of motion were accomplished, we believe, by the relief of muscle spasm with physostigmine. Surgery was no longer considered. One can argue that relief in this case might have resulted from weight reduction. However this may be, easing of pain and increase in motion were so sudden that one could not help but feel that it was the result of the drug. Furthermore, pain and spasm would return when there was interruption in treatment.

Case 6—*Calcified bursitis of three months' duration.* G. F., a man aged 61, complained of pain in the left shoulder with painful limitation of motion He had been treated previously with heat in various forms plus the use of histamine ointment. Physical examination was negative except for painful limitation of motion in the left upper extremity.

X-ray examination revealed a very large calcified bursa in the region of the head of the left humerus. The bone structure of this shoulder girdle was normal. There was no arthritis present. Subsequent x-rays (two months later) disclosed no significant changes in the amount of calcification present (fig. 2).

Therapy consisted of physostigmine salicylate and atropine sulfate 0 6 mg. hypodermically. Relief from pain was evident within one hour. In addition there was increased strength in the arm so that the patient could lift and hold objects. He was unable to do this before therapy was instituted Further treatment consisted of injections daily for three days, then three times a week for four weeks. There was continued improvement, as shown by the objective measurements and strength tests (table 4).

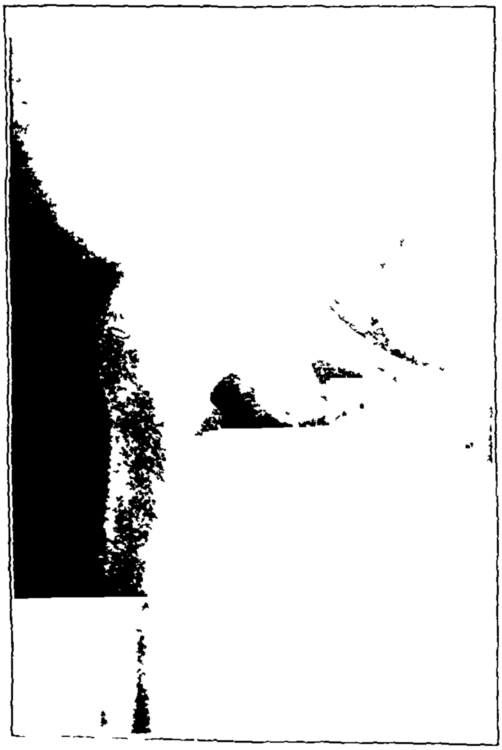

Fig. 1.—Osteoarthritis of right hip in case 5

This case serves to illustrate that calcification of the bursae may not always be entirely responsible for painful limitation of motion and disability.

Case 7.—*Bursitis of one year's duration.* G. K., a white man aged 50, seen May 24, 1945, complained of a painful immobile right shoulder. He had had similar attacks in 1940, 1942, 1943 and 1944 The diagnosis of calcified bursitis was confirmed by x-ray. All attacks were relieved in a reasonable period (ten days to two weeks) by x-ray therapy. The condition for which he was seeking treatment came on three months before, with pain and fixation of the shoulder girdle The patient could not place his right hand in his pocket. All movements caused severe pain X-ray examination revealed no evidence of old or recent injury or pathologic process to the bones of the right shoulder joint. The calcification previously described in the soft tissues of the right shoulder on April 16, 1943 had entirely disappeared, so that at the present time the entire shoulder appeared normal from the x-ray point of view. A point of tenderness could not be localized. It was now felt that the fixation was probably due to muscle spasm rather than to recurrent bursitis.

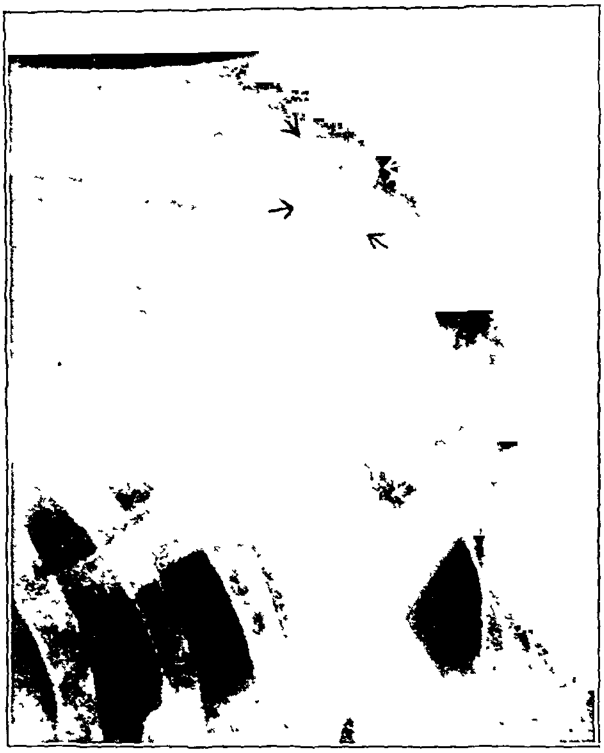

Fig 2.—Calcified bursitis in case 6

Table 4—*Measurements in Case 6*

Left Upper Extremity	Before Treatment	After
Forward flexion, straight arm	115°	160°
Abduction, straight arm ..	85°	110°
Backward flexion, straight arm	25°	45°
Left hand fingers touch.....	1. Occiput	Right ear
	2 Past midline of spine sacrum	All way around to right hip
	3 Barely touches right shoulder	Top of shoulder touched

Treatment consisted of physostigmine salicylate 0.6 mg. with 0 6 mg. of atropine sulfate subcutaneously. The patient immediately began to improve. With each injection there was continued improvement. He received treatment twice weekly for two months. He also received short wave diathermy and active exercise during this period.

CASE 8.—*Scalenus anticus syndrome of seven months' duration.* R. S., a white woman aged 43, seen Oct. 16, 1943, complained of pain in the neck and right shoulder radiating to the right elbow and wrist, and of numbness in the fingers of the right hand. The onset of this illness dated back about seven months. It came on with severe pain in the region of the neck and right shoulder, radiating to the right elbow and wrist. This was accompanied by numbness in the fingers of the right hand. On four occasions attempts were made to relieve the discomfort by infiltrations of procaine hydrochloride into the scalenus anticus muscle. The diagnosis of scalenus anticus syndrome was made by a competent surgeon. Operation of section of the muscle was advised. It was thought that the symptoms were due to spasm of the scalenus anticus muscle and that if the spasm could be relieved the symptoms might subside, thus obviating surgery.

Neostigmine methylsulfate 1 cc. 1:2,000 with 0.6 mg. of atropine sulfate was given intramuscularly on two successive days. For the next eight days treatment was repeated every other day. This was followed by a two weeks interval without treatment. Similar injections were then administered monthly. Reactions consisted of dizziness, abdominal pain with a desire to defecate, quivering of the facial muscles and restlessness. Subsequent adjunctive therapy consisted in the use of baking with the carbon filament bulb and deep massage.

Following the first injection pain was partially relieved, range of motion and power were increased, and numbness disappeared.

The patient has gradually made a complete recovery, no further therapy being required since March 1944.

It was not convenient to hospitalize all our cases in order that we might treat them as controls, and therefore in our statistical report we are reporting no controls. All cases herein described in detail were studied as controls, however, and a sufficient number used to form a feasible conclusion.

The cases classified as fibrositis consist of those in which pain in various joints was complained of, sometimes with contractures of the elbows but always a considerable amount of stiffness. There is a history of aches and pains over a period of years without much deformity and with a normal sedimentation rate usually.

All cases of rheumatoid arthritis were of more than six months' duration and all presented a rapid sedimentation rate.

SUMMARY AND CONCLUSIONS

1. Physostigmine salicylate has been used successfully in the relief of muscle spasm and associated conditions such as fibrositis and bursitis. It is an inexpensive form of therapy, replacing the more expensive neostigmine methylsulfate. Physostigmine appears to give local pain reactions less frequently than neostigmine.
2. Physostigmine, like neostigmine, causes relaxation of muscle spasm even though it has persisted for many years. As a result, active as well as passive motion in the affected joints is more easily carried out with less pain.
3. The effect of physostigmine given subcutaneously is rapid (within three to fifteen minutes after administration) and may persist for several days.
4. Further studies with neostigmine bromide orally do not warrant its continued use in the treatment of muscle spasm in rheumatoid arthritis and its allied conditions.
5. Physostigmine did not produce any severe toxic reactions.
6. The studies reported indicate that physostigmine is no more toxic than was neostigmine methylsulfate when used in comparable doses.
7. Physostigmine is used in the treatment of muscle spasm in rheumatoid arthritis and allied conditions for the purpose of relieving pain due to spasm and for preventing deformities.

TRAUMATIC RUPTURE OF THE SPLEEN IN CHILDHOOD

H. WILLIAM SCOTT JR., M.D., and J. ROBERT BOWMAN, M.D.
Boston

Rupture of the spleen is probably the most common serious subparietal injury to the abdominal viscera in any age group. Its early recognition and treatment in childhood is of especial interest to those who deal with the problems of early life. Seven children with traumatic rupture of the spleen have been observed by the Surgical Service of the Children's Hospital during the period of 1937-1944 inclusive. It is our purpose in this report to record our experience with these patients and to discuss some aspects of this injury in children.

Anderson[1] in 1939 reported 10 cases of ruptured spleen in children observed in a fifteen year period and reviewed the literature on 80 previously recorded childhood cases. The ages ranged from 4 to 15 years in her series and the sex distribution showed a male predominance of 3 to 1.

All our patients were boys ranging in age from 4 to 13 years. This is in keeping with the greater activity of males and their larger exposure to trauma.

ETIOLOGIC ASPECTS

Trauma to the abdomen resulting in rupture of the spleen is usually of a violent nature. Although open or penetrating wounds may readily produce splenic damage, in civilian practice rupture of the spleen is commonly a subparietal injury, frequently without evidence of external trauma. In Anderson's series of cases the injury was sustained most frequently in an automobile accident. Falls, kicks, blows, sledding accidents and indeed any heavy force applied directly to the splenic region may produce the injury. Rarely, indirect violence as in a fall on the left hip or the right side of the abdomen has occasioned splenic rupture.[2] Three of our 7 patients were injured in falls and 3 in sledding accidents; 1 was struck by a falling object. All sustained closed injuries, and only 1 showed any superficial evidence of trauma.

The mechanism by which trauma to the abdomen or lower thorax results in rupture of the normal spleen is not clearly understood, since the spleen is well protected by the costal cage and has a mobile attachment. A sudden increase in intra-abdominal pressure occasioned by blast injuries has been known to cause splenic rupture.[3] In adults the injury frequently is associated with fractured ribs, variously reported by different authors as from 10 to 20 per cent.[4] This combination of injuries is rare in childhood. Mazel[5] has suggested that in children the flexibility of the lower costal cage allows transmission of a blow directly to the spleen, resulting in rupture without associated rib fracture. There were no fractured ribs in our group of splenic injuries.

Dr. Bowman is resident surgeon, the Children's Hospital, and assistant in surgery, Harvard Medical School.

From the Department of Surgery, Harvard Medical School, and Surgical Service, the Children's Hospital.

Dr. Scott was formerly resident surgeon, the Children's Hospital; assistant in surgery, Harvard Medical School.

PATHOLOGY

Harkins and Zabinski[6] in 1943 classified rupture of the spleen under six headings which included spontaneous, traumatic and delayed rupture of the normal and diseased spleen.

While spontaneous rupture of the normal spleen is a questionable entity and warrants little consideration, spontaneous rupture of the diseased organ is apparently not uncommon. In childhood, however, the most important of the splenic injuries is traumatic rupture of the normal spleen.

The pathologic lesions encountered in subparietal rupture of the normal spleen have been arranged by Roettig, Nusbaum and Curtis[7] into five groups: (1) fragmentation of the spleen into two or more parts or complete detachment from the pedicle, (2) large laceration near the hilus, (3) a single large or many small tears of the periphery, (4) solitary small laceration of the periphery and (5) subcapsular hematoma.

In the 7 children with ruptured spleens observed at the Children's Hospital, the lesion could be classified as group 1 in 2 instances, group 2 in 4 and group 4 in 1 case. None of the spleens showed any pathologic changes other than those of trauma. It is interesting that 1 of the children had been successfully treated in the Infants' Hospital for erythroblastosis fetalis five years before his splenic injury. Although his spleen was enlarged in early infancy, it was not palpable after the age of 6 months. After the removal of this spleen for traumatic rupture the specimen was found to weigh 64 Gm. and microscopic study revealed no abnormalities other than those produced by trauma.

TABLE 1.—*Data from Seven Patients with Traumatic Rupture of the Spleen Treated at the Children's Hospital, Boston, 1937-1944*

Patient	Age	Sex	Injury	Symptoms	Clinical Examination	Interval from Injury to Operation	Operation	Result
1	5 yr.	♂	Fall	Diffuse abdominal pain; weakness; thirst	Pallor; tenderness R. U. Q.; B. P. 105/40; pulse 120; R. B. C. 3.5 million	9 hours	Splenectomy	Recovered
2	7 yr.	♂	Blow	Paroxysmal abdominal pain; vomiting; weakness; thirst	Pallor; tenderness L. L. Q.; B. P. 90/60; pulse 120; R. B. C. 4.85 million	8 hours	Splenectomy	Recovered
3	8½ yr.	♂	Fall	L. U. Q. pain; vomiting; left shoulder pain; weakness; thirst	Pallor; sweating; tenderness and spasm L. U. Q.; B. P. 105/72; pulse 96; R. B. C. 4.5 million	17 hours	Splenectomy	Recovered
4	13½ yr.	♂	Sledding accident	Diffuse abdominal pain; vomiting; left shoulder pain	Shock; tenderness and spasm max. L. U. Q.; dulness in flanks; B. P. 85/50, 65/50; pulse 120; R. B. C. 3.29 million	4 hours	Splenectomy	Recovered
5	10½ yr.	♂	Sledding accident	Diffuse abdominal pain; left shoulder pain; thirst; syncope	Pallor; cold extremities; tenderness and spasm L. U. Q.; shifting dulness; B. P. 104/72; pulse 124; R. B. C. 2.4 million	12 hours	Splenectomy	Recovered
6	5½ yr.	♂	Fall	Diffuse abdominal pain; vomiting; weakness; thirst	Pallor; diffuse abdominal tenderness and spasm; fluid wave; B. P. 98/50; pulse 104; R. B. C. 3.20 million	11 hours	Splenectomy	Recovered
7	4 yr.	♂	Sledding accident	L. U. Q. pain; vomiting; weakness; thirst; syncope	Pallor; tenderness and spasm L. U. Q.; fluid wave; B. P. 130/92; pulse 140; R. B. C. 3.5-2.6 (2 hrs.) million	30 hours	Splenectomy	Recovered

Delayed splenic rupture is encountered in about 14 per cent of all cases of ruptured spleen according to Harkins and Zabinski.[6] This syndrome is characterized by a "silent period" of at least twenty-four to forty-eight hours after the injury, followed by the sudden development of signs of acute blood loss. The pathologic lesion responsible for secondary hemorrhage usually is either a small peripheral laceration or a subcapsular hematoma. In the former, hemorrhage is delayed by a clot or by omental tamponade, while in the latter an expanding hematoma causes necrosis of the splenic capsule and subsequent bleeding.

Delayed rupture of the spleen was not encountered in our group of children, although 1 patient was not hospitalized until twenty-seven hours after his injury. During this period, however, there were symptoms of progressive blood loss.

CLINICAL ASPECTS

A child who has sustained an abdominal injury causing rupture of the spleen usually complains of abdominal pain, frequently in the left upper quadrant and occasionally referred to the left shoulder. The pain is shortly followed by evidences of acute blood loss. On examination there are pallor, anxious facies, varying degrees of shock, tenderness and spasm maximal in the left upper abdominal quadrant and with progressive and extensive bleeding, signs of abdominal fluid. Data from our 7 patients are summarized in table 1.

The abdominal pain of ruptured spleen in the Children's Hospital cases was of a diffuse, poorly localized nature more often than it was limited to the left upper abdominal quadrant. One child had paroxysmal pain resembling that of intussusception. The pain was referred to the left shoulder in 3 of these 7 children. This phenomenon, known as "Kehr's sign," results from diaphragmatic irritation and occurs in about 50 per cent of children with splenic injuries.[1]

The symptoms of acute blood loss were quite striking in every instance. All of the children complained of weakness and thirst, and 2 of them had fainted prior to admission to the hospital. Nausea and vomiting, probably related either to the shock of the initial trauma or to adynamic ileus associated with hemoperitoneum, occurred in 6 of the 7 patients.

Signs of acute blood loss were evident in every child on examination, although only 1 was in severe shock at entry with pallor, a pulse rate of 120 per minute, blood pressure 65/50, air hunger, sweating and cold extremities. All of the children were pale, and with a single exception the pulse rates were over 100. One child whose pulse rate was 140 had a blood pressure of 130/92, probably demonstrating the overcompensation of a labile vasoconstrictor system in the face of hemorrhage, as discussed by Harkins.[6]

[7] Roettig, L. C.; Nusbaum, W. D., and Curtis, G. M.: Traumatic Rupture of the Spleen, Am. J. Surg. **59:** 292-319, 1943.

Abdominal tenderness and muscle spasm were present in the left upper quadrant in 5 of these children. In 1 these signs were maximal in the right upper quadrant, and another had generalized abdominal tenderness and spasm. Pressure of the examiner's hand over the left upper quadrant in 1 patient produced left shoulder pain in a rather striking manner.

Signs of abdominal fluid as evidence of hemoperitoneum were elicited in 4 patients. In no instance was "Ballance's sign" encountered. This is described as increasing and nonshifting dulness in the left flank associated with signs of free fluid in the remainder of the abdomen. There were no palpable masses in the splenic region or elsewhere in any of our patients.

The erythrocyte count had fallen to 3,500,000 or less by the time of admission in 5 of these 7 patients, in 2 instances dropping as low as 2,600,000 and 2,400,000 before operation. Theoretically, blood loss from ruptured spleen causes an earlier and more profound reduction in blood volume than bleeding of equal degree from another source, since with splenic rupture the reservoir or "emergency" function of the spleen is not available as a compensatory mechanism in hemorrhage. Contrary to this hypothesis, 1 child had a red blood count of 4,500,000 on entry, falling to 4,070,000 within a two hour period. At operation he proved to have a small laceration of the splenic periphery of the group 4 variety. Another patient's admission erythrocyte count recorded five hours after injury was 4,850,000 despite a freely bleeding laceration near the splenic hilus.

TABLE 2—*Surgical Mortality in Subcutaneous Rupture of the Spleen*

(From Harkins and Zabinski, with additions)

Author	Year	No of Cases	Mortality, per Cent
Bessel Hagen	1900	37	46
Michelsson	1913	298	33
Buxton .	1922		29
McIndoe ..	1932	37	27
Anderson .	1939	9	33
Foster.	1940	20	30
Rousselot and Illyne	1941	17	29
Harkins and Zabinski.	1943	10	30
Roettig, Nusbaum and Curtis	1943	15	7
Scott and Bowman . .	1945	7	0

The leukocyte counts varied between 10,600 and 18,000 in this group of children on entry. Leukocytosis apparently is a physiologic response to trauma and hemorrhage and is not indicative of infection in such cases.

Roentgen examination of the lower thorax and abdomen was made in 6 of the 7 patients immediately after hospitalization. There were no evidences of fractured ribs or of ruptured hollow viscera. In our experience roentgenograms of the abdomen have not contributed to the positive diagnosis of splenic rupture. However, Solis-Cohen and Levine [8] as well as O'Neill and Rousseau [9] have described roentgen changes which they consider practically pathognomonic of rupture of the spleen. These changes include a dilated stomach with a serrated greater curvature and obliteration of the splenic shadow. Whether or not roentgenography is of aid in the diagnosis of ruptured spleen, roentgenograms of the thorax and abdomen are indicated in order to exclude associated injuries. The differential diagnosis includes contusion of the abdominal wall, fractured ribs, ruptured hollow viscus, ruptured kidney and lacerated liver. Any of these injuries may occur in conjunction with a ruptured spleen.

In general, a history of trauma to the abdomen, followed by symptoms and signs of blood loss with abdominal tenderness and spasm maximal in the left upper quadrant and a reduced or falling red blood count, are diagnostic of intra-abdominal hemorrhage and strongly suggestive of rupture of the spleen.

TREATMENT

As soon as a presumptive diagnosis of rupture of the spleen has been made, preparation for immediate splenectomy is indicated. Prolonged observation may allow the patient to become exsanguinated. A plasma infusion should be started while compatible blood is being obtained. The importance of having large amounts of whole blood available for continuous transfusion before, during and after operation cannot be overemphasized In our experience the amount of blood present in the peritoneal cavity at the time of operation has averaged between 500 and 1,000 cc. Sudden release of tamponade on opening the peritoneum may result in acceleration of the bleeding, further hampering the operative procedure and adding considerably to the total blood loss

The technic of splenectomy for ruptured spleen in children differs from the elective operation only in that immediate control of the pedicle is the first objective While a transverse or subcostal approach gives the best exposure of the splenic region, we usually have employed a long, left paramedian incision when traumatic rupture is suspected. Rapid laparotomy is facilitated by this incision, and thorough abdominal exploration can be carried out without extending the wound. After the removal of the spleen all blood is aspirated from the peritoneal cavity, and the abdominal contents are carefully examined for associated injuries. Drainage is not indicated.

During the postoperative period an elevation in blood platelets occurs with the accompanying danger of vascular thrombosis. Platelet counts should be performed daily after the third or fourth postoperative day in anticipation of a "platelet crisis." The maximum elevation in thrombocytes is attained usually at the end of the first or during the second week after splenectomy.[10] It is the policy of this service to begin heparinization for any evidence of thrombosis and prophylactically for an elevation in platelets above 800,000 per cubic millimeter. Heparin is continued until symptoms have abated or until the platelet count has fallen below 800,000. Only 1 of our 7 patients developed symptoms suggestive of vascular thrombosis. These consisted of abdominal discomfort and vomiting associated with a platelet count of 900,000, occurring on the eighth postoperative day. Heparinization resulted in prompt relief of symptoms, but, because of persistent thrombocytosis, roentgen therapy to the thorax was given. Thereafter the platelet count subsided and the patient recovered uneventfully.

Davis and Sharpe [11] in 1938 discussed splenic vein thrombosis following splenectomy and concluded that this uncommon complication was most apt to result from the disease process necessitating splenectomy rather than from the operation itself. Recently, however, Gius, McGovern and McMurray [12] reported a case of splenic and portal-vein thrombosis which apparently followed splenectomy for traumatic rupture. This complication was not encountered in any of our patients.

One interesting sequela to splenectomy for traumatic rupture of the spleen is the condition known as "splenosis" or autoplastic transplantation of splenic tissue to the peritoneal surfaces. This condition is said to occur more commonly in young persons.[13] We have had no opportunity to observe this phenomenon in our patients.

COMMENT

The 7 patients with traumatic rupture of the spleen observed at the Children's Hospital from 1937 to 1944 were treated by splenectomy and all recovered. The general mortality resulting from this injury in all age groups as indicated by the literature has averaged about 30 per cent. In recent years the mortality rate has declined (table 2). This may be attributed to earlier recognition with prompt surgical intervention and to the greater availability of blood and blood substitutes and their use in replacing the blood loss.

Six of our 7 patients were operated on within three hours after entry, while 1 was observed for sixteen hours before splenectomy was performed.

To postpone operation after a presumptive diagnosis of splenic injury has been made is often disastrous. Because of the great danger of delayed splenic rupture, even a seemingly trivial laceration of the spleen should be treated by splenectomy rather than by attempted suture of the defect.

COLLOIDAL SALT NASAL TAMPONADES: THEIR USE AND ABUSE

GEORGE D. WOLF, M.D.
Assistant Clincal Professor of Otolaryngology, New York Medical College
New York

There is probably no other type of nasal therapeusis so empirical and yet so widely used as that of nasal tamponades saturated with a solution of mild protein silver. Both rhinologists and general practitioners have employed it for years in a wide range of nasal disorders. Some of their advocates have made bizarre claims that these nasal packs, introduced under certain specifications, will relieve or even cure any and all nasal disturbances from nasal "catarrh" to empyema of the antrum; they even go so far as to believe that such therapy will cure asthma and even some ocular afflictions. Yet the merits of these tamponades have never been scientifically proved; indeed, the fact remains that many observers have accumulated considerable evidence to the contrary.

All along there has been a great lack of unanimity of opinion among authorities on this confused question, some notable workers standing stanchly by the use of the treatment, while others, equally reliable in their field, have considered it ineffective and even harmful.

Dowling[1] in 1910 advocated the beneficial use of nasal tamponades and subsequently published many papers in support of his observations. Since then many authors have substantiated his claims. Thus the treatment gained considerable acceptance.

Voorhees[2] in 1934 endeavored to estimate the popularity of the method and sent out a questionnaire to 7,300 eye, ear, nose and throat specialists to ascertain how many of them used silver colloidal preparations in their practice. He received 2,948 responses, of which 88 per cent declared that they used silver salts in one form or another. The replies were not sufficiently detailed to make it possible to judge whether these salts were used in the form of drops or of nasal tampons, but it seems fairly clear that many of the specialists used it in the form of tamponades.

Although it is common knowledge that general practitioners and rhinologists frequently employ this form of treatment in cases of acute and chronic sinusitis, a careful search of the literature on this subject during the past twenty-five years shows that no comprehensive or critical review of the subject of nasal tampons with colloidal salts has been made.

The standard textbooks either ignore the subject or commit themselves merely to some such statement as "nasal tampons[3] . . . colloidal silver . . . are undoubtedly of value in some cases but are not the panacea they were formerly believed to be." "Tamponade[4] with a mildly stimulating solution is used by many men." "The common[5] 'silver pack' method, of doubtful value, is usually so distasteful to children as to render it unsuitable in this age group."

This does not mean, however, that the method is without its strong supporters. Such a well known authority as Dean[6] claims that . . . so far, argyrol has given the best results in this class of cases, both clinically and also in experimental sinusitis in animals. Another supporter of the method is Boies,[7] who thinks that application of tampons soaked with 15 per cent mild protein silver in equal parts of glycerin and water, applied to the middle meatus or above the middle turbinate, or both, seems to be effective in the subacute cases of sinusitis.

Among the supporters also are found Williams and Mousel,[8] who in discussing the treatment of allergic patients claim that two to four tablets of histaminase taken before each meal will often cause a remarkable disappearance of polyps with reduction of edema and that such simple measures as shrinkage with the "Dowling pack" followed by gentle suction will effect a cure of secondary infection of the sinuses.

Gable,[9] also on the side of the pros, finds that a treatment most satisfactory both to the patient and to the physician is the placing of tampons saturated with a colloidal silver solution in the region of the ethmoid cells, a procedure which by osmosis removes the excess fluid from the mucous membrane, thus effecting a definite shrinkage.

Equally positive are those of the opposing camp. Nadler[10] finds no physiologic basis for the use of local applications, irrigations or tampons or for the use of antiseptics such as organic silver preparations, since these cannot be brought in contact with all of the organisms in the nose. He feels that the nasal mucosa must be responsible for its own defense. Bowers[11] feels that the results obtained from the silver "pack" are due to osmosis by drawing water out of the tissues and that hypertonic saline solutions can do this equally well. Furstenberg[12] has eliminated the "pack method" from his clinic, as he feels that irritating solutions are contraindicated because gauze or cotton tampons can do injury to the delicate membranes. Swain[13] agrees that injury may be done by knocking off ciliated epithelium with the cotton applicators; also that colloidal silver preparations excoriate the mucous membranes. Mithoefer[14] has no faith in this method, and Walsh and Cannon[15] and Proetz[16] find its antiseptic value very doubtful.

With such leading authorities lined up in one camp or another, the confusion to the average practitioner who wishes to discriminate becomes very apparent. An attempt will be made to clarify the issue.

HISTORY OF COLLOIDAL SILVER

The therapeutic effect of certain of the metallic elements, especially of mercury and silver, has been known since ancient times. Thus Izar[17] reports that as long ago as the Macedonian era wounds were covered with silver plates. In parts of Italy erysipelas was still treated this way in the early part of this century.

Cary Lea in 1891 obtained dispersions of silver in water, but these aqueous solutions were unstable as they had no protective colloid added.

Credé meanwhile became interested in the therapeutic potentialities of silver and experimented with the effects of silver nitrate as compared with silver lactate, citrate and other forms. He introduced colloidal silver in 1896, and this instituted the use of colloidal metals as therapeutic agents; at the present time silver is probably one of the most important of the metals employed for this purpose.

Credé made use of Cary Lea's dextrin solution. At the present time pharmaceutical houses have put a large number of commercial products on the market which carry names indicative of the method of preparation or of the protecting colloid which is added to ensure their stability. Some of the solutions most frequently encountered, together with the protective colloid each contains, are "Argentum Credé" or Collargol (dextrin), Argyrol (vitellin from egg yolk), Dispargin (acid degradation product of gluten), Lysargin (sodium lysalbinate), Protargol (sodium protalibinate), Sophol (nucleic acids and formaldehyde) and Electrargol, an electrically dispersed solution, protected by gelatin.

PHARMACOLOGY

The effectiveness of colloidal silver is due to the immediate irritant properties produced by the free silver ions and subsequent mild antiseptic effects produced by the resolution and ionization of the silver protein compounds that were formed in the first stage.

Careful laboratory tests[18] prove that mild protein silver salts U. S. P. cannot be relied on to destroy Staphylococcus aureus in the presence of the concentration of organic matter used in the experiments. However, they rated somewhat better against Eberthella typhosa. The strong protein silver U. S. P. was effective against both organisms but rated slightly lower than noncolloidal compounds.

According to Goodman and Gilman[19] the antiseptic activity of a given preparation is not in proportion to the total content of silver but is due rather to the function of free silver ions. They further state that the indiscriminate use of colloidal silver solutions, especially in prophylactic treatment of upper respiratory infections, is probably doing more harm than good . . .; it is quite possible that they may injure tissue cells. Nor do Goodman and Gilman find any evidence that the routine use of silver solutions for prophylaxis of colds is at all efficacious.

The strong protein silver group, according to New and Nonofficial Remedies, is most effective but is slightly irritant and stimulant. The mild protein silver group acts largely as a mucilaginous demulcent, and its action is protective and detergent through the dislodging of pus.

EXPERIMENTAL STUDIES

Since it is a well known fact that nasal packs with colloidal silver bring about an increased flow of mucoid discharge, laboratory research on the influence of mucin in relation to the virulence of pathogenic germs is of great interest. The investigations of Nungester and his co-workers[20] produced unassailable proof that when bacteria are suspended in sterilized mucin and injected intraperitoneally, subcutaneously or into the lower air passages they become so injurious to the animal host that it frequently dies from a small sublethal dose; in other words, "the virulence of bacteria in the presence of mucin is greatly increased." The authors offer the following comments: "The mechanism of the action is not yet understood. Mucin does not interfere with phagocytosis but does inhibit the bactericidical properties of phagocytic cells. It enables bacteria to survive in the body of the host for longer periods without diminution in number, or it may allow the organisms to increase in number and so result in the death of the animal. The viscosity and cohesive properties of the mucin appear to be important indices to the effectiveness of mucin on bacterial infections."

Does it not seem logical to infer, therefore, that any agent which increases the flow of mucin of the nose is harmful rather than beneficial?

UNFAVORABLE EFFECTS

Bryant[21] emphasizes the danger of argyria resulting from the use of silver preparations for intranasal medication. He states that a review of the literature shows a decided increase in such cases in the last five years. He concludes that intranasal medication with silver preparations for even weeks is dangerous and "accomplishes nothing that cannot be accomplished safely and more efficiently by other means."

Criep[22] reported a case of allergy to argyrol (mild protein silver). There was evidence of sinus infection (with sneezing, nasal blockage, rhinorrhea and wheezing) developing during local application of the drug. After the throat had been sprayed with argyrol for treatment of pharyngitis, severe asthma developed. Scratch skin tests with 1 per cent argyrol were positive in the patient; passive transfer tests were carried out and specific antibodies against argyrol found. Intradermal tests with similar dilutions of U. S. P. mild protein silver (Solargentum and other brands) gave negative cutaneous reactions and negative passive transfer tests; local nasal tampons with these preparations caused no local symptoms of asthma. He questions whether allergic responses to argyrol are as rare as they are believed to be and suggests that symptoms may be so mild as to pass unrecognized by rhinologists.

PHYSIOLOGY OF THE NOSE

For a more intelligent approach to nasal therapy it is essential to consider that many nasal disturbances are physiologic in nature rather than pathologic, or a combination of the two.

Respiration, the most important nasal function, is intended to warm and humidify the inspired air on its way to the lungs. The structure of the nose also filters the air of dust particles and bacteria, the coarser particles being caught by the vibrissae of the nares, while finer particles are seized by the cilia and the mucous blanket. The mucous membrane of the nasal cavity and sinuses is lined with ciliated epithelium. The cilia are vigorous, resistant and powerful and possess a great regenerative faculty. The motion of the cilia is somewhat similar to grass or wheat being waved by the wind as it sweeps along the thin coat of the overlying mucus.

The film of mucous secretion extends over the nose, sinuses, trachea and esophagus into the stomach. The flow varies in rate and direction, that in the nose being directed toward the nasopharynx. Mucus is thin, elastic, slippery and tenacious, and it readily encloses and carries away foreign matter. Mucus movement is most active in the ciliated area in the posterior two thirds of the nose, where it is renewed about once every ten minutes. Bacteria are swept quickly away from the active areas, and the deeper portions of the nose are often found to be sterile. The natural defenses of the nose, therefore, are due to ciliary action and are not necessarily aided by nasal antiseptics. Probably there are also natural antibodies against bacterial agents.

INDICATIONS FOR AND AGAINST TAMPONAGE

From a scientific point of view, and according to the clinical evidence of some competent observers, one would infer that colloidal silver should have no place at all in nasal therapeusis. Yet it cannot be denied that nasal "packs," when used routinely, do give the patient temporary relief lasting from twenty-four to forty-eight hours. It is impossible to determine whether this relief is due to the osmotic, mildly astringent and antiseptic value of the drug. Some contend that the same results would be obtained with saline solution. It may also be that the suction of the superfluous nasal discharge which usually follows the tamponage effects a temporary palliation.

Aware of the contradictory opinions expressed in the literature as to the value of this medication, I have given this therapy a thorough and unbiased trial both in hospital and in private practice over a period of years, so as to form an opinion regarding this controversial topic. Careful notations have been made on the symptomatic relief following this treatment in a wide variety of types of nasal disorders.

I have concluded that colloidal silver tamponage is at best of dubious curative value in definitely purulent sinusitis or where there is physical obstruction in the structure of the nasal vestibule such as a considerably deflected septum, hypertrophied turbinates or polypi. In allergic patients this treatment often aggravates the symptoms.

On the other hand there is a class of patients, constituting a small percentage of those with nasal disorders, who complain of vague headaches, nasal stuffiness and discharge. This picture frequently occurs in stocky individuals of both sexes.. Inquiry reveals that they have a tendency to overeating and indiscreet indulgence in rich foods, and that their bowels are sluggish. In addition, there may be evidence of overactivity of the sebaceous glands in the face and scalp. X-ray examination of the paranasal sinuses is usually negative except for a mild thickening of the mucous membranes lining them, especially those of the ethmoids. Except for the absence of sneezing, the clinical picture revealed by nasal examination is very similar to that seen in allergic patients: the nasal mucous membrane is congested and thickened, the inferior turbinates are boggy and the nares are filled with thick mucus.

Before submitting these patients to allergic tests or search for eosinophils, I have found it practicable to insert gently tampons medicated with 10 per cent colloidal silver solution. If this is followed by a very profuse mucoid discharge from the nose, saturating one or two towels, and if a yellow ropelike mucous discharge is sucked out of the nose, it is likely that the patients will experience long lasting relief after several such treatments. They usually volunteer the information that their heads feel clearer after such therapy. The most reasonable explanation of the favorable results obtained is that the symptoms are due to hyperactivity of the glands of the schneiderian membrane of the nose. In addition to receiving local treatment, these patients are advised to seek the aid of an internist for correction of their diets and mode of living. Small doses of thyroid are a good adjuvant.

It is immaterial whether similar results can be obtained with medication other than the silver protein solution, since this drug is relatively harmless if judiciously used and not applied over too long periods of time. In all other types of nasal disorders tamponades, although innocuous, are entirely ineffective, except for a very brief respite of the patients' complaints.

COMMENT

Solutions of mild protein silver used in the form either of nasal drops or of tampons have enjoyed considerable popularity both with the profession and with the public.

Up to the present time we have no definite scientific proof or statistical data to support the curative claims or the great enthusiasm expressed by the proponents of this medicated tamponage. Though there is reasonably good evidence against the indiscriminate employment of tamponage, in some well selected instances this treatment produces very satisfactory results.

[22] Criep, L. H.: Allergy to Argyrol, J. A. M. A. **121**: 421-422 (Feb. 6) 1943.

CONCLUSION

1. When used as a tampon in the nasal cavity, colloidal silver solution is limited in its local therapeutic effects.
2. There is no reason to believe that any particular technic employed in applying these tampons will produce superior results.
3. The best that can be claimed for it is that its action is due primarily to its free silver ions.
4. When the nose is packed tightly with tampons, some ciliary damage occurs.
5. There is no adequate excuse for having patients tamponaded over a period of months or years.
6. The mischief in the continued nasal packing lies not so much in the act of commission but rather in that of omission. In other words, the patient is receiving palliative care rather than a correct diagnosis, in a stage when chronicity could be avoided.
7. There is a particular type of so-called nasal "catarrh" in plethoric and obese persons which yields to such tamponage, the relief lasting at times for months without requiring interval treatment.
8. Allergy to protein silver, although rare, and possible argyria after prolonged use must be borne in mind.
9. Prolonged nasal tamponage as a routine method for the cure of chronic sinusitis has no physiologic or pharmacologic basis in the therapeutic armamentarium of either the rhinologist or the general practitioner.

Clinical Notes, Suggestions and New Instruments

FRACTURE OF THE FIRST CERVICAL VERTEBRA, COMPLICATED BY CERVICAL RIB

ALBERT P. GUADAGNI, M.D.
Surgical Resident, St. Luke's Hospital
San Francisco

Fractures of the cervical vertebrae are not very unusual. Fractures of the first cervical vertebra are fairly rare. For this reason it would seem desirable to report a fracture of the atlas whenever encountered.

The present case illustrates a few unusual features. Plaut,[1] in a review of this injury in 1937, stated that the commonest cause for this type of fracture is a blow on the vertex of a patient looking forward, in an upright position. Under these circumstances the fracture is produced by a pressure on the vertex and counterpressure from the spine below; that is, pressure between the condyles of the occiput and the lateral masses of the axis. The weakest point of the atlas lies in the arches, both posterior and anterior, and fractures occur through these areas, with lateral displacement of the fragments. The patient who is the subject of the present report was standing in the hold of a vessel, looking forward, and was struck on the vertex with a sack of grain. It should be noted that the falling object was rather soft and consequently produced a pressure injury on the cervical vertebra rather than a direct fracture at the point of contact at the vertex. Hard objects striking the vertex are more likely to produce a depressed fracture of the skull at the vertex, or a basilar fracture. If the head is not fixed in a vertical position but is inclined somewhat forward, compression fractures of the cervical vertebrae, particularly the fifth and sixth, may be expected, instead of a fracture of the atlas. Fractures of the atlas are not uncommonly encountered in automobile accidents.[2] The mechanism here apparently is that the patient is thrown upward, usually from the rear seat, striking the vertex against the roof of the automobile. Here again a slower type of pressure is experienced

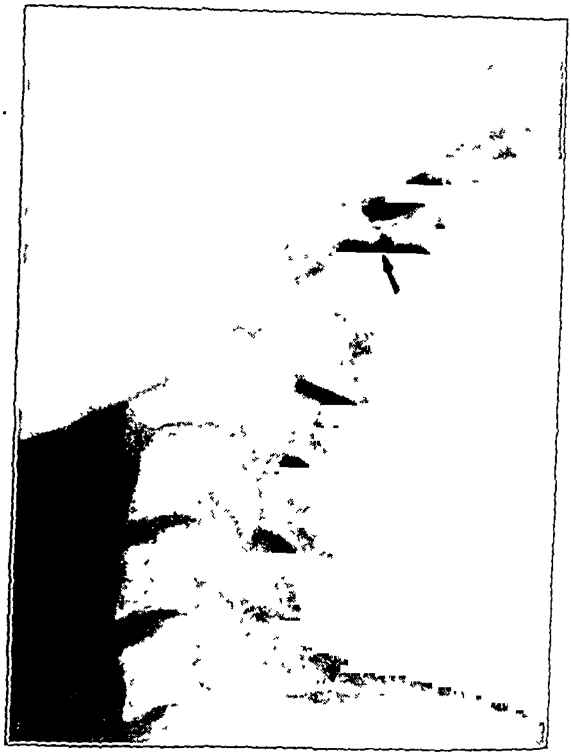

Fig 1.—Lateral view, showing fracture.

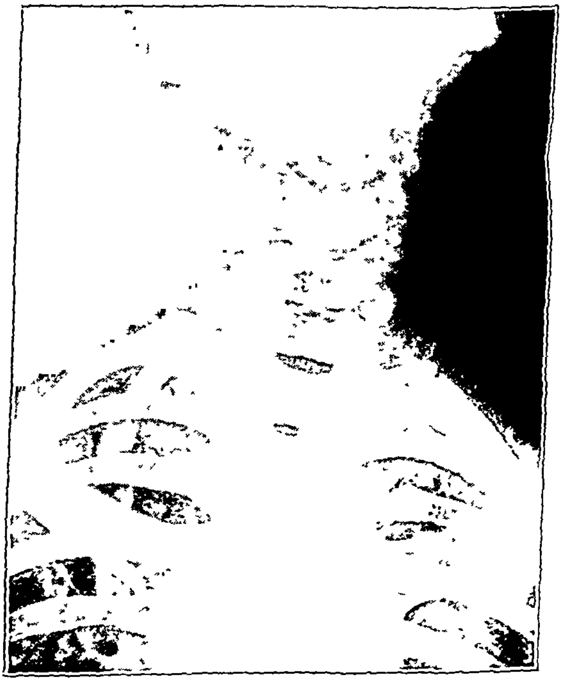

Fig 2.—Anteroposterior view, demonstrating the cervical rib

Dr. George McChesney cooperated with orthopedic consultation.

[2] Plaut, H. F.: Fracture of the Atlas in Automobile Accidents, J. A. M. A 110: 1892 (June 4) 1938.

and the mechanism is quite similar to that of a semisolid blow on the vertex.

Sinberg and Burman[3] state that the fracture may b unilateral or bilateral and in the posterior arch where the lateral masses are narrowed by the groove of the vertebral artery. However, it is necessary to differentiate these fractures in the x-rays from congenital bony defects. Lack of fusion of the posterior arch may produce a bony defect which is usually near the posterior tubercle, with rarely more than a width of 10 mm. The characteristic fracture, of course, is recognized by the sharp edges of the fracture line and subsequent disappearance of this line and the development of callus.

REPORT OF CASE

B. R., a Negro aged 40, admitted to St. Luke's Hospital to the service of Drs. G. D. Delprat and Alanson Weeks on Dec. 15, 1944, had been struck on the head by a sack of grain weighing about 100 pounds about two hours prior to admission. At the time he was standing erect and facing straight forward. He believes he was unconscious for a few seconds and was then aware of lying on the ground and having severe "pain" in the base of the skull "and a pain in the right shoulder." On admission he had nuchal and right shoulder pain and tingling in the right upper arm. X-rays showed a fracture of the first cervical vertebra near the junction of its posterior and middle thirds, the fragments being in satisfactory position. Also there was a long rib attached to the right transverse process of the seventh cervical vertebra.

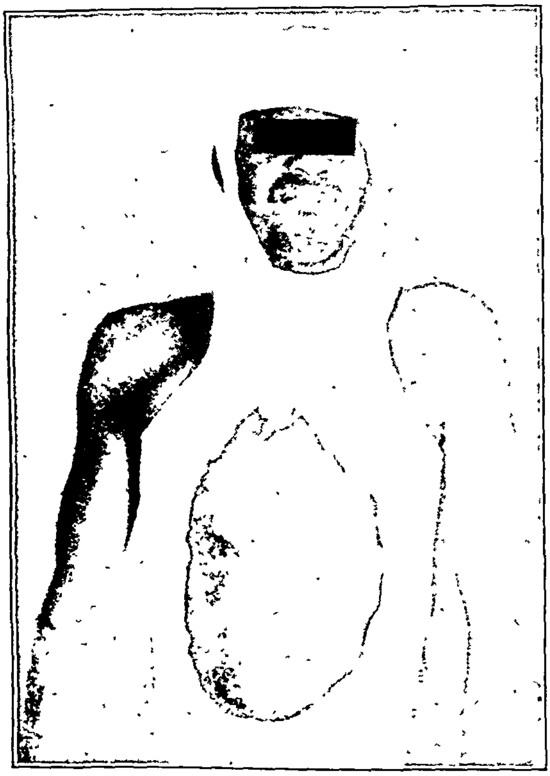

Fig. 3.—The cast.

Preliminary treatment consisted of head traction, with only slight relief, and hot compresses to his painful shoulder. On December 19 he was placed in a plaster jacket with a helmet included, this holding the head in slight extension and with great comfort to the patient. On December 28 he was allowed up in a chair and after a few days was able to walk. The patient was subsequently discharged ambulatory.

On Feb. 9, 1945 the cast was removed and x-ray examination at this time showed the fragments to be in good position with callus present. A plaster (Thomas) collar was then applied, this being split after eight weeks to allow physical therapy three times weekly, the collar being reapplied after each treatment. After a month the collar was removed permanently. X-ray examination on March 7 showed partial bony union with the fracture line still visible, and a film on May 4 showed almost complete bony union.

At present the patient still has physical therapy three times weekly for residual stiffness and slight pain in the neck. Rotation of the head is limited about 20 per cent. He has occasional ulnar paresthesia in the right hand apparently due to the presence of the aforementioned cervical rib.

Council on Foods and Nutrition

ACCEPTED FOODS

The following additional foods have been accepted as conforming to the Rules of the Council on Foods and Nutrition of the American Medical Association for admission to Accepted Foods.

George K. Anderson, M.D., *Secretary*.

PREPARATIONS USED IN THE FEEDING OF INFANTS (*See* Accepted Foods, 1939, p. 156)

Beech-Nut Packing Company, Canajoharie, N. Y.

Beech-Nut Strained Custard Pudding contains milk, sugar, rice, cornstarch, whole eggs, egg yolks, salt, vanilla and water.

Analysis (submitted by manufacturer).—Total solids 22.90%, moisture 77.10%, ash 0.88%, fat (ether extract) 2.05%, protein (N × 6.25) 2.38%, crude fiber 0.15%, carbohydrates (other than crude fiber) 17.44%, calcium 0.075%, phosphorus 0.060%, iron total 0.37 mg. per hundred grams, iron "available" (Bipyridyl method) 0.17 mg. per hundred grams, copper 0.15 mg. per hundred grams, specific gravity 1.08.

Calories.—98 per hundred grams, 28 per ounce.

Vitamins.—	Per Hundred Grams
Vitamin A, total	207 U. S. P. units
Thiamine	0.012 mg.
Ascorbic acid	0.018 mg.
Riboflavin	0.154 mg.
Niacin	0.18 mg.

Heinz Company, Pittsburgh.

Heinz Strained Custard Pudding contains rice, sugar, salt, 50 per cent cream, whole milk powder, whole eggs, cornstarch, vanilla concentrate and water.

Analysis (submitted by manufacturer).—Total solids 23.57%, total sugar as sucrose 10.81%, acidity as lactic 0.07%, protein (N × 6.25) 2.98%, fat (by acid hydrolysis) 2.34%, ash 0.75%, salt 0.43%, total carbohydrates by difference 17.43%, calcium 81.0 mg. per hundred grams, phosphorus 61.0 mg. per hundred grams, iron 0.04 mg. per hundred grams, copper 0.05 mg. per hundred grams.

Calories.—1.03 per gram, 29 per ounce.

SATURDAY, FEBRUARY 2, 1946

PARA-AMINOBENZOIC ACID THERAPY FOR TSUTSUGAMUSHI FEVER

Encouraging data as to the therapeutic value of para-aminobenzoic acid in the treatment of experimental tsutsugamushi disease (scrub typhus or "dangerous bug" disease) are reported by Snyder and his associates[1] of the Cairo unit of the United States of America Typhus Commission. Previously Zarafonetis,[2] a member of the typhus commission, had found that 2 small mouselike rodents (Gerbillus gerbillus and Gerbillus pyramidun) common in Asia, Africa and southern Russia are readily susceptible to Rickettsia orientalis. When inoculated intraperitoneally, subcutaneously or intravenously 100 per cent of the gerbilles succumbed to the disease. Smears of the peritoneal and pleural exudates showed numerous pleomorphic rickettsias within the cytoplasm of the pus cells. Following reported beneficial effects of para-aminobenzoic acid in the treatment of classic louse borne typhus in human beings,[3] the commission tested its possible therapeutic effect on gerbilles after lethal inoculation with several different strains of Rickettsia orientalis. The diet of the control gerbilles was a wet mash composed of 80 Gm. of dried, powdered Egyptian bread, 2 to 4 Gm. of sodium chloride, 60 cc. of milk and 40 cc. of tap water. Immediately after inoculation the treated rodents were changed to an identical diet in which 40 cc. of 9 per cent sodium salt of para-aminobenzoic acid was substituted for tap water in the mash.

In a typical experiment 15 rodents were inoculated with a 1:10 dilution of the peritoneal washings from a fatal case of the disease. All 7 of the normally fed control animals died between the ninth and the twelfth day after inoculation. Of the 8 treated animals but 3 died, a survival rate of 62.5 per cent. In a second series inoculated with a 1:100 dilution of the same peritoneal exudate all control animals died, while the survival rate was 87.5 per cent in the animals fed on the sodium salt of para-aminobenzoic acid diet.

Since gerbilles feed only at night, a new plan of therapy was then adopted. In this plan all gerbilles given this diet received a supplementary subcutaneous injection with 0.1 cc. of a 10.4 per cent solution of the sodium salt of para-aminobenzoic acid per 25 Gm. of body weight every eight hours from the fifth to the seventeenth day after inoculation. Of 130 control gerbilles inoculated with various multilethal doses of Rickettsia orientalis only 2, or 1.5 per cent, survived. Of 128 gerbilles given the same multilethal doses and afterward treated with the combined technic 105 survived, a survival rate of 82 per cent. The survival rate was as high as 90 per cent in certain other groups similarly treated. From these and other data the typhus commission recommends a clinical trial of the sodium salt of para-aminobenzoic acid in human tsutsugamushi disease. Clinical evidence[3] with epidemic louse borne typhus has shown that it is safe to give para-aminobenzoic acid to man in large amounts.

The commission offers no theory to explain these successful therapeutic results. A plausible theory, however, was suggested at an earlier date by Greiff[4] of St. Louis University. Greiff reported a similar therapeutic success from feeding 3 per cent para-aminobenzoic acid to mice previously infected with murine typhus rickettsias. He believes that the therapeutic effects were due to metabolic stimulation of host cells. This is in line with Zinsser's[5] earlier experimental evidence. Zinsser found that, under conditions of high metabolic activity as determined by rate of oxygen consumption, multiplication of intracellular rickettsias did not occur in Maitland tissue cultures.

The probability that para-aminobenzoic acid therapy is equally applicable to all rickettsial infections is increased by the demonstration by Anigstein and Bader[6] that 2 per cent para-aminobenzoic acid added to the diet of guinea pigs previously inoculated with Rocky Mountain spotted fever will usually protect them from all signs of the disease. Untreated control guinea pigs almost invariably succumb to the infection. Successful treatment of 1 human case of Rocky Mountain spotted fever by orally administered para-aminobenzoic acid has been reported by Rose and his associates[7] of Columbia University. The efficiency of para-aminobenzoic acid in the treatment of Carrion's disease and trench fever, however, has not yet been reported.

ORGANIZATION AGAINST CANCER IN GREAT BRITAIN

In 1942 cancer of the breast in the United Kingdom caused 7,877 deaths, of the uterus 5,094, of the larynx 1,206, of the tongue 1,033, of the lip 290. As these forms of cancer are curable in their early stages, the measures at hand to control cancer could probably have been used to better advantage. In the United States cancer of the breast in 1943 caused 16,140 deaths, of the uterus 16,968, of the larynx 1,490, of the tongue 1,231, of the lip 661. Unless treated effectively in the early stages cancer usually is fatal; hence high death rates from cancer of the forms mentioned indicate grave inadequacies in clinical cancer service, whatever the special reasons may be.

The problems of the practical application of the British Cancer Act of 1939 are now under the active consideration of governmental agencies and of medical societies.[1] In discussions on cancer both English and American physicians repeat that the patient frequently delays seeking medical care in good time from ignorance and fear. The physician may and often does fail to recognize early cancer. Nuttall [1] states that in England the condition is far advanced in 45 per cent of cancer patients when they first seek expert advice mainly because of their own fault but also to some extent of failures by attending physicians. The urgent need persists for continuous education in regard to the importance of early recognition and treatment of cancer. Cancer should be detected more and more at the stage when its presence usually can be proved only by skilful examinations. Patients should be taught to report symptoms as soon as noticed, and opportunities for immediate consultation and necessary aids to diagnosis should be provided. The slightest suspicion of cancer should be promptly confirmed or dispelled. The British Cancer Act provides not only for sufferers from cancer but also for those "suspect of cancer." When the diagnosis of cancer is made, there must not be any delay in skilled treatment. To meet these needs fully will require organized cancer services known to every practitioner and freely available to every patient, no matter what his means may be.

The British plan is to divide the country into self-contained regions with diagnostic units, treatment centers and facilities for the care of advanced cases. Public and private hospitals are to partake in each regional organization, with headquarters in a university city and with the necessary subcenters. Adequate facilities are to be organized for radiotherapy as well as for general and special surgery. The developments of British cancer services under governmental auspices will be observed with interest by all concerned with the control of cancer. Thus far there seems to be little evidence to prove that the system that prevails in Sweden, which provides free diagnosis and free transportation to government clinics, has materially reduced the deaths or death rates from cancer.

SILLY NAMES FOR PENICILLIN PRODUCTS

The name "penicillin," which truly reflects the source of the product, was deliberately chosen as a descriptive title. The modesty of the investigators led them to avoid eponyms. Now, however, leaders in the drug and chemical industries, apparently avid for the kind of profits that can be derived from well exploited medical specialties, have let their imaginations and their greed run riot in a search for specific trade names to designate some penicillin products.

In the January 1946 issue of *New Modern Drugs* are some extraordinary examples of this deliberate degradation of science. Instead of selling penicillin under its simple and well known name, they have become downright silly and offer penicillin under so many names that only a professional solver of crossword puzzles could guess the nature of the products that these names conceal.

Wyeth, Inc., is credited with marketing Amphocillin, Penioral and Bucillin, Squibb with Topicillin and Delacillin, Lederle with Ledercillin-G, and Hoffmann-La Roche, Inc., with Per-Os-Cillin. Some of these are for oral use, some for local application, one is to be mixed "before taking" with something else. The promulgators of these products and their sale are interested in helping their own pocketbooks by trying to make certain that the prescribing physician will limit himself to their products. One manufacturer naively combines his firm name with "cillin." There are more than twenty manufacturers. Carried to a logical conclusion that would give us not only "Ledercillin" but also "Squibbcillin," "Abbottcillin," "Schenleycillin" and "Commercial Solventscillin" plus some others.

But who could guess that Amphocillin and Bucillin refer to penicillin for oral use? Who can believe that Delacillin is really penicillin calcium in peanut oil and beeswax? You might surmise the nature of Ledercillin-G, but we will lay 8 to 5 that you would miss on Penioral. Would you think it useful especially for gonorrhea? Well, that isn't it. Then what about Per-Os-*Cillin*? Something concerned with an opening, but which one?

Some day scientific aims and business promotion will be more closely knit. When that day arrives every one will breathe a sigh of relief, including the promoters. Perhaps they will finally realize that a scientific approach gains the confidence of the prospective buyers and really promotes use. Until then, time marches on.

SCIENTIFIC RESEARCH IN THE FOOD AND PHARMACEUTICAL INDUSTRIES

Recent addresses[1] before associations of manufacturers have stressed the funds spent on research. Of the manufacturing industries the food industry is the most important, since its products are of the first concern to the people. This industry employs more persons and produces more goods than any other industry. The food industries entered directly into scientific research, pure and applied, about twenty-five years ago as bulk sale on a commodity basis gave way to specialty sale on a brand basis. Research is conducted by single concerns and by groups. Numerous organizations carry on research in various divisions of the food industry. The Nutrition Foundation promotes the development of the science of nutrition. Recently[2] the foundation made sixteen grants to universities in aid of research amounting to $108,000. The major basic research in nutrition has been done and presumably will be done in universities and other centers of pure research. The food industry is deeply interested in the maintenance of this activity by these institutions in the most effective way.

What is the food industry actually spending for scientific research? Dunn's estimate is 24 million dollars a year, which is 10 per cent of what all industry is reported to have spent for research in 1940. In discussing the plans and prospects for expanding the scientific research of the food industry as the basis for progress in its business and service, Dunn voices serious concern over the present deficit in scientists. The reduction in bachelor's degrees in science which would have been given but for the war is about 150,000, and only 20 per cent of the usual number of doctorate degrees in chemistry and physics were awarded in 1945.

Second only to the food industry as an agency of human health and welfare comes the pharmaceutical industry. Here too progress in business and service depends on scientific research. In answer to the question how much this industry is spending on scientific research, Dunn presents estimates showing that in 1944 the amount so spent was 12 to 14 million dollars. He points out that, calculated in percentages of sales, the pharmaceutical industry appears to be spending more for scientific research than any other major branch of manufacture. And the industry looks forward to the progressive expansion of its research activities. In all scientific research, especially the pure and fundamental, the culmination of each advance is the beginning for new advances.

The keynote of these discussions of industrial expenditures for research is that progress in the food and drug industries as economic and social organizations depends on scientific research not only to reduce the costs of their products but particularly to produce new and better foods and drugs.

Current Comment

IS TUBERCULOSIS FULLY REPORTED?

The United States Public Health Service has recently released statistics on the number of cases of tuberculosis reported in relation to the number of deaths by states. Several states show a ratio of 1.0: Arkansas, South Carolina, Texas and Vermont. Rhode Island, on the other extreme, reports 5.8 cases of tuberculosis for every death recorded in that state. The simple mean in all the states reporting is 1.9 cases per death. This wide variation implies either that tuberculosis is much more frequent in some states than in others or that the thoroughness of tuberculosis case reporting varies widely. Figures from England indicate about 15 cases of tuberculosis per registered death, but the comparability with those of the United States is questionable. The evidence suggests that the recording of cases of tuberculosis in many parts of this country is incomplete. Unless this deficiency can be remedied it is almost impossible to evaluate the true proportions of the tuberculosis problem in the United States. Physicians are responsible for reporting all cases of tuberculosis to their local health departments and should see to it that this obligation is fulfilled.

SOCIAL AND ECONOMIC FACTORS IN INFANT MORTALITY

For years physicians have known that infant mortality is greatest in slum areas and that it is influenced by social and economic factors. Possibly these are more significant than the factor of medical care. Professor Dugald Baird[1] of the University of Aberdeen has analyzed the influence of social and economic factors on stillbirths and neonatal deaths. He concludes that the most probable explanation of premature labor is poor health and nutrition of the mother and that the stillbirth and neonatal mortality rates will be most substantially improved by improvement in the standard of health and nutrition of mothers in the low income groups. He found that prematurity is greater in Scotland than in England and also greater than in America. His statistics indicated that the excess of neonatal mortality in Scotland is due largely to the excess mortality from prematurity. The most common obstetric condition associated with prematurity is eclamptic toxemia, which he found to be twice as common among the poor as among the well-to-do for the same age and parity groups. Surveys showed that in Scotland before the war there was twice as much poverty as in England, unemployment was greater, and slums and squalid living conditions were much more common. A careful study of the growth of women indicated that inadequate nutrition during the period of growth results in failure of the pelvis to develop properly, so that improvement in nutrition during pregnancy increases the risk because the child is large in relation to the size of the pelvis. From his study of the situation Dr. Baird concludes that improvement in social and economic conditions is the most important single factor in bringing about a reduction in the stillbirth and neonatal mortality rates in Scotland. Women of the lower income groups have poor physique and poor general health. Therefore continued improvement following better diets and better health services given to the mother during pregnancy is not the important factor. He is convinced that a minimal rate cannot be attained until all mothers have had the advantage of good food and environment from infancy to adult life.

IMMOBILIZATION OF LUNGS

Barach[1] reports the results obtained on 10 patients with advanced pulmonary tuberculosis who were treated by immobilization of both lungs in his equalizing pressure chamber. Cessation of voluntary respiration occurs in the living subject when an adequate flow of oxygen into the lungs and elimination of carbon dioxide are provided. Under these conditions the proprioceptive reflexes from the lungs do not stimulate lung movement. The individual remains comfortable, free from cyanosis, without the impulse to breathe and with a motionless chest. The chemical factors in breathing take precedence over proprioceptive reflexes. The equalizing pressure chamber was developed to apply equal pressure on the inner and outer surfaces of the chest wall at the same time. Continuous arrest of normal breathing was accomplished when patients were exposed to the equalizing pressure chamber in which the same alternating pressure wave of 110 mm. of mercury was produced, but a partition between the head and the chest of the chamber made possible a simultaneous arrival of an equal pressure on the two surfaces of the chest wall. The ability to dispense with the impulse to breathe required training, which was achieved by 1 patient in a period of forty-five minutes and by the majority of patients in three to four hours. Arrest of lung movement did not create any discernible changes in the circulation. There was no apparent change in the venous pressure, pulse rate, arterial blood pressure or circulation time. When voluntary respiration is abandoned, the impulse for movement of the voluntary muscles is strikingly diminished. Local lung rest favors the process of healing by reducing changes in the physical state of the tuberculous process and, in addition, has a specific effect on cavities in which a check valve action is present. The patients were treated in this chamber from 8:30 in the morning until 9:30 at night, being removed for meals. A course of therapy in most instances consisted of four months. The condition of all patients in the series was considered either too advanced or unsuitable for thoracoplasty. Significant improvement in the condition of 6 of the 10 patients was observed. The author concludes that this type of local lung rest aids the process of healing and tends to result in collapse of cavities.

NUTRITION IN REVIEW

The Joint Legislative Committee on Nutrition of New York State, under the chairmanship of Senator Thomas C. Desmond, in its 1945 report[1] makes a number of recommendations, among them that the state recognize the need for an expanded program of nutrition education, encourage research in the field of nutrition, give new recognition to the special nutrition needs of children, give greater consideration to stiffer penalties for black marketeering and lend its influence to further experiments in the fluorination of community water. "Nutrition in Review" (Legislative Document [1945] No. 49) contains a number of interesting reports, among them an illuminating one by Dr. John M. Cassels on "The European Food Situation," on "Nutrition in Industry" by Dr. Thomas Dobbins and on the "Newburgh-Kingston Caries-Fluorine Demonstration" by Dr. David B. Ast. The report emphasizes in particular the importance of education as carried on by Cornell University, by the New York State Emergency Food Commission and by the Nutrition Foundation and the War Food Administration.

MILK TRANSMISSION OF DDT

Telford and Guthrie[1] of the Hess-Clark Research Laboratory, Ashland, Ohio, fed female rats each of which had a 1 day old litter a balanced chick mash containing 0.1 per cent of DDT. Typical tremors were noted between the sixth and thirteenth days in the mothers and between the fourteenth and fifteenth days in the young. By the eighteenth day all were dead except 1 adult and 1 nursling. Both recovered when placed on a diet free from DDT. Nine adult rats and one half-grown kitten were then fed solely on milk obtained from goats which received daily oral dosages of 1 Gm. of DDT per 8 to 9 pounds (3.6 to 4.1 Kg.) of body weight. All 10 died within two to twenty-nine days after exhibiting typical DDT tremors. Butter made from the toxic milk produced typical toxic symptoms, with eventual death in a second series of adult rats. These preliminary experiments prove that continuous oral administration of DDT to goats and rats results in the appearance of a toxic substance in their milk which produces symptoms indistinguishable from DDT intoxication. The data strongly suggest the need for more intensive research on the toxicity of milk from dairy cows which ingest DDT residues either from sprayed or from dusted forage plants or from licking themselves after being sprayed or dusted with this insecticide.

MEDICINE AND THE WAR

SURPLUS MEDICAL EQUIPMENT FOR VETERANS OF WORLD WAR II

A procedure has been worked out whereby veteran physicians, dentists and veterinarians may purchase surplus army medical equipment directly from the disposal agency. The authority for this procedure is found in Public Law 457, 78th Congress, and appropriate regulations have been issued by the Surplus Property Administration.

In order to assist the individual in obtaining surplus property, there has been prepared by the Surgeon General of the Army, in collaboration with the disposal agency, a listing of items by army medical catalogue number, standard commodity classification number and army nomenclature, together with a price set by the disposal agency. This listing includes material appropriate for a professional office which was available as "declared surplus" in various army medical depots at the time the list was prepared. Supplemental lists are to be furnished as additional items become available. Copies of this list are being made available in service command headquarters, various army hospitals, medical depots and disposal agency offices. This listing should be used by individuals in preparing requests. It should be understood that not all of this material will be available in any one particular region, nor will the quantities of any given items be sufficient to satisfy all purchasers.

Veteran physicians, dentists or veterinarians should apply to the district office of the Smaller War Plants Corporation which is located nearest the veteran's residence. Effective January 28, district offices will be absorbed by the War Assets Corporation; however, it is expected that these district offices will remain in the same location. District offices are maintained in approximately one hundred and ten of the major cities throughout the country. The function of certifying applicants as to their eligibility to purchase surplus property, now performed by the Smaller War Plants Corporation, will be assumed by the War Assets Corporation as of January 28.

Having obtained certification that the applicant is a veteran and that the property applied for is to be used in his own small enterprise, prospective purchasers may present their requirements to the nearest regional office of the disposal agency or to the nearest district office of the War Assets Corporation, listing quantities desired by stock number and nomenclature as shown on the listing. Regional offices of the Office of Surplus Property RFC have also been absorbed by the War Assets Corporation, effective January 15, at which time the War Assets Corporation, a subsidiary of RFC, assumed the disposal functions for which the Office of Surplus Property RFC had heretofore been responsible. Regional offices are located as follows:

Atlanta 3, 105 Pryor St. N.E.
Boston 11, 600 Washington Street.
Chicago 4, 209 South La Salle Street.
Cincinnati 2, 704 Race Street.
Denver 2, 728 Fifteenth Street.
Fort Worth 2, Post Office Box 1407.
Los Angeles 14, Pacific Mutual Building.
Kansas City 8, 2605 Walnut Street.
New York 1, 350 Fifth Avenue.
Philadelphia, Lafayette Building, Fifth and Chestnut streets.
San Francisco 2, 30 Van Ness Avenue.
Seattle 1, 2005 Fifth Avenue.

Regional offices will advise the applicant as to items, quantity, condition, price, availability and location of material within that region. An extract, listing items desired but not available in that region, will be forwarded by the regional office to the central stock control point in Washington. Information as to availability in other regions will be furnished by the Washington office to the regional office for transmittal to the applicant. This information will also include the quantity, condition, price and location of these items. On receipt of this information, the applicant will notify the War Assets Corporation regional or district office of the items desired, *forwarding certified check* for the total amount involved. The disposal agency will then order shipments from the army or navy storage depot, where located, in accordance with the detailed shipping instructions supplied by the applicant. Shipment will be made, transportation charges collect, to be paid by the consignee.

Although samples of equipment are available for inspection by the purchaser, they are located in various depots throughout the United States, and it is impracticable to assemble all the items in one or more locations for inspection. Further, it is impracticable for individual purchasers to visit the numerous depots where material is located in order to inspect prior to purchase. It is not possible, in case individual items of equipment are inspected by purchaser, to tag any particular piece of equipment for the individual purchaser to be held pending receipt of shipping order from the disposal agency. Purchasers are familiar with army and navy equipment, having worked with it during their military service. Prices for new, unused equipment, in excellent condition, have been set by the disposal agency. The material is classified according to condition and will be billed by the disposal agency at fair value. Prices will be scaled downward if used equipment is furnished. If only new, unused equipment, in excellent condition, is desired, applicants will so state and depots will not make substitution of material in less desirable classification. All claims and adjustments will be handled by the War Assets Corporation. These claims must be presented to the district or regional office handling the original request for purchase. It must also be understood that surplus property sales are in progress at all times and that delivery of all items selected by the applicant cannot be guaranteed, nor will back orders be established. Payments for equipment not furnished will be refunded. To the extent of availability, equipment will be shipped from the medical depot nearest the destination designated by the purchaser. However, surplus stocks are not evenly distributed throughout the army and navy medical depot system, and shipments of some of the equipment will have to be made from depots at a considerable distance from the destination.

VETERANS

APPROVE WINTER GENERAL HOSPITAL FOR VETERANS ADMINISTRATION

President Truman recently approved the transfer of Winter General Hospital, Topeka, Kan., from the Army to the Veterans Administration as part of a plan for acquiring twenty-nine new hospitals and one home for Veterans Administration use.

Dr. Karl Menninger, who served as consultant in neuropsychiatry for the hospital under army control, has been named as temporary manager of the installation until the hospital is functioning regularly and then will resume his position as consultant to the Veterans Administration.

Dedication ceremonies of the Winter General Hospital, Veterans Administration, took place on January 11.

APPOINTED DIRECTOR OF TUBERCULOSIS SERVICE

Dr. John B. Barnwell of the University of Michigan, Ann Arbor, was recently appointed director of the Veterans Administration tuberculosis service, with Col. Roy A. Wolford of Washington, D. C., as associate director.

A new program for examination and care of tuberculous veterans was recently begun, of whom there are now approximately 100,000. The purpose is to prolong the good effects of hospital treatment after a veteran leaves a tuberculosis institution and to discover, at an early stage, any relapses.

ARMY

5,000 ASTP MEDICAL OFFICERS TO BE CALLED AS REPLACEMENTS

In a recent release the War Department stated that more than 5,000 young medical officers will be called to active duty by July 1 as replacements for officers of the Medical Corps who are eligible for separation from the service. These doctors, after receiving their academic training in medicine under the Army Specialized Training Program, are now completing their training by serving internships and residencies in civilian hospitals on an inactive status.

Information of the early call to active duty has been sent to all civilian hospitals by the Surgeon General of the Army and by the Procurement and Assignment Service for Physicians, Dentists and Veterinarians.

The 5,000 doctors being called to active duty are graduates of the Army Specialized Training Program whose tours of active duty as medical officers were scheduled to begin when they had completed hospital internships and residencies, essential professional preparation not available in military installations.

Approximately 3,300 enlisted men now assigned to ASTP units for training in medicine will receive the degree of Doctor of Medicine by July 1, when the ASTP medical program is to be discontinued. This group will be called to active duty at the completion of their internships. The enlisted men assigned for instruction in the freshman, sophomore and junior classes in medicine will be separated from the program in March. Those who plan to continue their medical studies will be transferred to the Enlisted Reserve Corps and released from active military duty in order to continue their medical training in a civilian status.

Men separated from medical training under the ASTP who do not plan to continue their medical studies will be transferred to other military duties and continued on active duty until they become eligible for separation from the Army under current War Department policies.

ARMY AWARDS AND COMMENDATIONS

Captain Neil M. Forbes Jr.

The Silver Star was recently awarded to Capt. Neil M. Forbes Jr., formerly of Laurel, Miss., who served as battalion surgeon for the 185th Infantry, 40th Division. The citation stated that the award was made for gallantry in action Feb. 16, 1945, when "Captain Forbes, without regard for his own persontal safety, constantly exposed himself to heavy enemy fire to care for the wounded. On one occasion Captain Forbes received word that a soldier had sustained a severed jugular vein from enemy shrapnel on top of a hill. Realizing the danger to the patient's life and the slowness of the litter haul down the hill, Captain Forbes left the aid station, climbed part way up the hill and there, while under enemy sniper and mortar fire, worked for one and one-half hours and saved the man's life. Captain Forbes's tireless devotion to duty, his disregard for his own safety when lives of our troops are at stake, and great courage have been an inspiration to the men and a credit to the Army of the United States." Dr. Forbes graduated from the University of Tennessee College of Medicine, Memphis, in 1941 and entered the service July 2, 1942.

Lieutenant Colonel John Groopman

Lieut. Col. John Groopman, formerly of New York, was recently awarded the Air Medal "for meritorious achievement in aerial flight. He completed 151 hours of combat and operational flight between Oct. 23, 1943 and July 31, 1945, flying from bases in North Africa, India and China. These flights were made in the performance of his duties as flight surgeon and were made in unarmed transport type aircraft. Despite the dangers involved from probable attack from enemy aircraft and ground installations and adverse weather, Lieutenant Colonel Groopman demonstrated courage and determination in carrying out his missions. He went to the aid of wounded and ill personnel at forward bases and evacuated them to rear areas for treatment. The achievements of Lieutenant Colonel Groopman during the period cited reflect credit on his personal record and on the Army Air Forces." Dr. Groopman graduated from New York University College of Medicine, New York, in 1932 and entered the service Oct. 5, 1940. He has also been awarded the Purple Heart and the Soldier's Medal.

Major Cortez F. Enloe Jr.

Major Cortez F. Enloe Jr. of Manhasset, L. I., N. Y., was recently awarded the Bronze Star. The award was accompanied by the citation "for meritorious service in connection with military operations as chief medical sciences branch, Morale Division, U. S. Strategic Bombing Survey, from Feb. 5, 1945 to May 8, 1945. Because of his thorough medical professional knowledge, his technical and scientific experience in the pharmaceutical and biological industry and his knowledge of German medical and health affairs Major Enloe was given the difficult and responsible assignment of preparing plans and directing the Medical Science Branch of the Morale Division, U. S. Strategic Bombing Survey, in the scientific study of the effects of aerial bombardment on the health of the German civilian population. His enthusiasm, diplomacy and complete knowledge of his task enabled him to direct successfully the military and civilian scientists assigned to his command in the accomplishment of their medical research mission. The data compiled by this study will be of inestimable value in the future national defense plans of the United States." Dr. Enloe graduated from Friedrich Wilhelms Universität Medizinische Fakultät, Berlin, Prussia, in 1937 and entered the service Sept. 18, 1942.

Major Hugh M. Crumay

The Bronze Star and two oak leaf clusters to the Air Medal were recently awarded to Major Hugh M. Crumay, formerly of Mercer, Pa. The citation read, in part, "As air evaluation officer, Medical Section, Headquarters Far East Air Forces, Major Crumay demonstrated exceptional initiative and sound judgment in the performance of his duties." Dr. Crumay graduated from Harvard Medical School, Boston, in 1933 and entered the service July 17, 1942.

MISCELLANEOUS

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

INDIANA

Memorial Hospital, South Bend. Capacity, 275; admissions, 9,180. Mr. Vernon T. Root, Administrator (interns, July 1).

LOUISIANA

Shreveport Charity Hospital, Shreveport. Capacity, 654; admissions, 10,320. Dr. Edgar Galloway, Medical Superintendent (resident—radiology).

NEW JERSEY

St. Joseph Hospital, Paterson. Capacity, 468; admissions, 7,636. Sister Anna Rita, R.N., Superintendent (resident—mixed service).

NEW YORK

Cumberland Hospital, Brooklyn. Capacity, 400; admissions, 5,729. Dr. Max Seide, Medical Superintendent (interns, April 1, July 1).

St. Vincent's Hospital, Staten Island. Capacity, 238; admissions, 5,920. Sister Mary Ignatius, R.N., Superintendent (interns).

General Hospital, Syracuse. Capacity, 170; admissions, 3,822. Mr. Carl P. Wright, Superintendent (interns).

Wyoming County Community Hospital, Warsaw. Capacity, 135; admissions, 2,699. Mr. W. A. Copeland, Superintendent (resident—mixed service).

OHIO

Lutheran Hospital, Cleveland. Capacity, 160; admissions, 4,926. Mr. Lee S. Lanpher, Superintendent (interns).

Youngstown Hospital, Youngstown. Capacity, 622; admissions, 17,297. Mr. David A. Endres, Superintendent (interns).

SOUTH CAROLINA

Columbia Hospital, Columbia. Capacity, 506; admissions, 8,902. Mr. P. A. Hodges Jr., Acting Superintendent (8 interns, April 1).

PHYSICIANS SEPARATED FROM SERVICE

ARMY MEDICAL CORPS OFFICERS RECOMMENDED FOR/OR RELIEVED FROM ACTIVE DUTY

Arizona

Herianek, Z. A., Capt., 906 Professional Bldg., Phoenix.

California

Bergman, H. H., Major, 3596 Mountain View, East Pasadena.

ORGANIZATION SECTION

PRESS COMMENT ON COMPULSORY SICKNESS INSURANCE

After President Truman sent his message on health to the Congress and the Wagner-Murray-Dingell bills were introduced, newspapers throughout the nation commented principally on the controversial compulsory sickness insurance feature. A majority of editors were opposed to extension of federal control over medical practice. Many considered the proposal merely a first step toward state socialism.

The Shreveport (La.) *Times* said, for instance:

> Actually, the danger rests not in adhering to the present system but in venturing to experiment with Wagner's socialism. It is in the latter direction that the hazards are found, the grave risk that, in destroying incentive for progress in medicine, this progress will be ended.
>
> No one contends that the present system is perfect. But no one can say honestly that it is not moving toward perfection, as rapidly as movement can be made safely in such a complex field, involving the lives and welfare of millions of Americans.

And then the Shreveport *Times,* after quoting almost wholly the editorial from THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION of December 1, concluded:

> Regardless of whether *The Journal of the A. M. A.* is right in every detail of its editorial comment, it is quite evident that if federalized compulsory sickness insurance is not socialization it is a full step toward it; and socialization of the medical profession, in whole or in part, would be exactly the step the Washington theorizers would like to take toward socialization in far broader fields.

Many newspapers were highly complimentary to the quality of medical care available in the United States. The Kansas City (Mo.) *Times,* after quoting largely from THE JOURNAL editorial of December 1, concluded regarding the application of compulsory sickness insurance to America:

> Its use in America is a question entirely too big for any hasty decision. The real question is whether it would not be far better to continue and further improve a medical system that has given this country health standards superior to those in any country that has adopted the compulsory plan with all its threatened regimentation and political control.

The Grand Rapids (Mich.) *Press* said:

> One might concede the need for federal participation in the medical and hospital field were it not for one thing—and that is that nationally we have steadily been making notable progress in the extension of health services without the intervention of the government. On the other hand, there is no assurance that the quality or scope of medical care would be greatly advanced under any federally supervised program. We do know, however, that such a program would be expensive, that it would compete with existing institutions and that it would bring virtual regimentation to a field where thousands of delicate problems depend for their solution on individual and confidential relationships.

The Fillmore (Neb.) *Chronicle* commented:

> The medical profession cannot be accused of being blind to the public interest. It has lifted the health standards of this nation higher than in any "socialized" nation. Its opinions should receive the most careful consideration.

The Baltimore *Sun* defended the quality of medical service generally available in the United States and described some of the many plans that have been developed to meet voluntarily the costs of medical care by prepayment insurance. It concluded:

> In these varied programs is found striking evidence of the widespread consciousness of the need for better medical care looking to the ultimate goal of adequate care for all. Some of the programs may fail, for this is a typical American approach to a problem by the trial-and-error method. But where one succeeds other communities will be prompt to adapt it to their needs. Whatever may come out of it, we may be sure that health care will be far better than any we have known before.
>
> Should this movement be ignored and discarded before we learn what it can do? Should we abandon this richly varied experimental approach for a set of alluring blueprints? This is what the advocates of a comprehensive scheme of tax-supported medical care, centrally administered by the federal government, are asking us to do. They are asking the country to throw away a system of medical care which despite many defects is fundamentally sound, and which is subject to constant improvement as experience points the way, for an entire new and untried plan.

As might be expected, the Chicago *Sun* in a number of editorials came out strongly for compulsory sickness insurance. Indeed it was certain that compulsory sickness insurance would be bound to prevail, saying:

> It can be asserted with utmost confidence that some such system of medical care will be realized in this country at a not too distant date. Complacency about national health has been shattered by the shocking revelation of widespread unfitness among draftees and servicemen. Thousands of families have experienced the financial catastrophe of sudden illness which might have been eased or avoided by prepayment on insurance principles. The benefits of adequate care have been brought home to many young men and women who got such care for the first time while in service. The tide of public demand for better health will grow and swell until it can no longer be resisted.
>
> Thus the real question before the medical profession is whether a national health program shall be put into effect with their aid and advice, or against their stubborn opposition. There may be legitimate differences of opinion on mechanics, but the principle of spreading the cost of medical care is here to stay. An enlightened medical profession will throw off the restraints of a misguided leadership and join the people in this great effort to broaden the base of national health.

In another editorial it urged that the medical care program be paid for principally from general taxes, not from payroll taxes, because it said:

> Payroll taxes clip mass purchasing power at its source, and it is essential to keep purchasing power high. If the nation has a stake in national health, as it does, then part of the burden can most appropriately be borne by general taxes based on ability to pay, rather than by payroll deductions, which, like sales taxes, fall most heavily on the low incomes.

Finally, it attacked the proposal that voluntary plans developed on a nonprofit basis in the individual states meet the situation, concluding:

> But the strongest point against the doctors' "plan" is that it will not accomplish what the people demand of medical insurance—an equitable spreading of medical costs among sick and well, rich and poor. Voluntary insurance would be open, as at present, only to those who can afford it and have the foresight to buy it. Low-income families would be excluded, as they are now; and so would millions of borderline families whose margin between income and outgo is so thin that medical expenses are never met until illness strikes.
>
> By putting forth their "alternative," the doctors admit the need for basic change in the economics of medical care. But by refusing to face the issues they fail to meet the need.

The Chicago *Daily News* said:

> The question is: what would it actually do; what would it actually cost; is it worth what it would cost; can we afford what it would cost, and what would its secondary effects be on medical practice and human welfare?

And then it said:

> Resentment of wage earners against the "deducts" is part of the troubled national psychology at this time. Workers tend to think of their wages as the amount that's left after the deductions. They often object to counting bonds, so readily cashable that they are the equivalent of cash, as part of take-home pay.
>
> If anything like Mr. Truman's plan is adopted, labor will demand wage increases to make up the cost.

Many editors felt that the President was apparently unaware of the relationship between compulsory sickness insurance and socialization of medicine. The New York *Sun* felt that the President should have studied more carefully the extent to which his proposal represented socialized medicine. It said:

> It will seem to many persons that President Truman has not gone far enough in testing this plan for marks of socialized medicine. It is true that physicians would not be employees of the federal government, but the intervention of Washington at every stage between the first sneeze and the last gasp would be so constant as to suggest state-dominated medicine, at the very least. The federal government would have complete control over collection and distribution of funds; it would have a corresponding say in fixing various standards to be met by communities or individuals. If this did not lead to socialized medicine, it would clearly result in firm establishment of federal control over a large area of medical practice.

The New York *Evening Post,* however, heartily endorses compulsory sickness insurance, assuring the doctors that it would give them more income and that it would not affect the personal relationship between physician and patient. The New York *Post* concluded:

> The President has proposed a democratic solution to a pressing national problem. If the entrenched minority of doctors, centering around the Fishbein clique in the American Medical Association, succeed in killing it by their screams against "socialized medicine," they may finally get just that.

The Nashville (Tenn.) *Banner* said:

> Leaders in the medical profession know the dangers invited by political control of medicine, however glibly its advocates dress it in words of innocence. . . . It is hardly likely that thinking American citizens will prefer political voices to authoritative medical voices on a subject involving life and health. It is inconceivable that thinking citizens will permit subjection of Medicine to the principles of boondoggling or assign it to the arrogant, untender mercies of bureaucracy.

And the Mount Carmel (Ill.) *News* went directly to the issue, asking:

> "When the federal government forces a person to subscribe to a prepaid medical system sponsored by the government, is there any other name for it but 'state medicine'?" It continues, "In order to have your free choice you may have to pay your medical bill twice—once to the government for a doctor you don't want and again to the doctor of your actual choice."

The Omaha *World Herald*, among others, feared the political domination of medicine. It said:

> As a matter of fact Dr. Washington is something of a quack. His rates are the highest in the world, but his patients often come down with palsy and creeping paralysis. And once they get into his clutches they are likely to stay there until the undertaker comes.
>
> Let it be hoped, even at this late hour, that the American medical profession will be spared such a fate. For despite anything its detractors may say, American medicine is the best in the world. Nowhere in the socialist or totalitarian lands is there anything to match it.

The Columbus (Ohio) *Evening Dispatch*, after calling attention to a strike of dentists in Great Britain against the health insurance system, says:

> For "dentists" read "doctors"; for "Surrey, Sussex, Kent and Hampshire" read "Ohio, Pennsylvania, New York and New Hampshire"; for "false teeth" read "appendectomies" or any common operation—and for the figures given substitute appropriate amounts.
>
> This shows what could happen in the United States with the practice of medicine regimented by political controls. Bureaucracy and human nature are the same over here as in the British Isles. A few words such as this one to the wise—meaning the American voter—should be sufficient.

Discussing the President's message, the New York *Sun* found it confused and said that the main trouble seems to be "anxiety to please as many persons as possible and to offend as few as possible." It continues:

> So, also, in his message on universal military training the President advocated it for men of certain ages, but didn't want these young men enrolled in the armed services—as neat a balancing of water on both shoulders as anybody could imagine. Likewise he has come out in favor of universal medical insurance—to be paid for largely by taxation—but says he opposed socialized medicine!

Apparently some editors were also confused. The Laguna Beach (Calif.) *South Coast News* has

> "always felt that the public health is a legitimate field for state action, and belongs in the same category as public education, fire and police protection, and other simple public utilities."

It offers the suggestion that local committees composed of both member and nonmember doctors set the rates for practice and that in each area

> "every registered M.D. may participate in a legal election to choose a committee to define standards for granting federal funds."

The *Wall Street Journal* too felt that the issue needed clarification. It said:

> Throughout the message the President asserts, not without reason, that his recommendations are based upon the insurance principle of pooled risks and pooled funds with which to cope with individual disasters and disabilities. He states, too, his conviction that his nationwide system of medical services "must be highly decentralized in administration." If one recalls the prolonged and at times bitter controversies which the age-pension reserve fund and state versus federal control of unemployment compensation have provoked, one must gain some idea of the greater struggles which a "required prepayment" system of providing such intimate relationships as medical, dental and nursing care must go through before it is established by federal law.
>
> We see little chance that Congress, despite the energy and intelligence with which its committees carry on their inquiries, can prepare itself to legislate wisely on the complex group of questions which Mr. Truman's latest message puts before it. A commission of the right sort could do much invaluable spade-work.

Then also the Asheville (N. C.) *Citizen* says "the Truman proposal is imperfect but it is no monster. It merits serious discussion, not cheap abuse." It further says:

> The American people, the *Citizen* ventures to believe, do not want "socialized medicine" in the correct definition of the phrase. But they are not satisfied with the present system. They wish to see competent medical attention brought within the economic reach of all the people.

The Washington (D. C.) *Post* praised highly the President's message to Congress demanding a national health program and concluded:

> There is nothing un-American about meeting the problem of ill health through social action. What the President has proposed is simply an orderly method of meeting the burden of medical care through prepayment and a reasonable distribution of that burden so that medical care can be genuinely available to all. He may be off the mark in detail, but he is right in principle and policy. Health, like education, must be the concern of our whole society, and we trust that the subject will receive the constructive attention that the presidential message deserves.

The Washington (D. C.) *News* indicated that none of the proposals made by Mr. Truman are new and that it is about time that there be a real hearing on the subject. Then it said:

> And we aren't trying to be facetious when we add that consideration of these and all other proposals involving government spending should take due account of the health of the federal treasury. Some sort of insurance against a continued decline into deeper and deeper debt is urgently needed there.

The New York *Times* indicated the support which the President's health program may anticipate as follows:

> The President may count on much support. Behind him stand the AFL and the CIO, both of which have endorsed not only compulsory health insurance but the payroll deductions and contributions by employers called for by the Wagner-Murray-Dingell bill; the American Public Health Association, which has a program much like his; the philanthropic organizations as a whole; some associations of liberal physicians, and powerful unions of farmers. Public health officers, too, will support the President, because his plan provides hope that at last they will be able to extend their activities to whole counties where there have been few physicians and too often no hospitals and laboratories at all.

The *Times* then emphasized the immense costs and the great size of the national debt.

The *Farmers Guide* (Huntington, Ind.) said that the American people "are exceedingly weary of compulsory this and compulsory that. They would like nothing better than to be permitted to live at least part of their lives unbossed by federal or union bureaucracies." The *Farmers Guide* continued:

> If we can be compelled to set aside a part of our earnings for medical care that we may or may not need, why should we not be compelled to set aside another percentage to insure against dandruff or baldness or graying hair?
>
> The President now appears as an advocate of compulsory military training, of compulsory medical insurance, compulsory price fixing, compulsory union membership and a host of other compulsions.
>
> Why not include matrimony, paternity and membership in either the Democratic or Communist party?

Finally the Alexandria (La.) *Daily Town Talk* offered a calm summary of the situation:

> Americans do not take well to compulsory anything, except in grave national emergencies, and then they rapidly return to voluntary action as soon as the crisis has passed.
>
> Medicine now stands at a sort of crossroads. Behind it is a long, stately avenue that is dotted with monuments that represent the noble achievements of the profession under the American system of free enterprise. Across that road there seems to stand a rather impenetrable road block of social change. The road to the left is marked "Compulsory Sickness Insurance," and from it there runs a collateral road that is even darker, called "State Medicine." On the other hand, we can turn down the road to the right, which leads us into that realm of voluntary social security occupied by the various voluntary prepayment plans that have been developed for the administration of medical care. From this road extends also a collateral road of continued individual private practice of medicine.

Coming Medical Meetings

Annual Congress on Medical Education and Licensure, Chicago, Feb. 11-12. Dr. Victor Johnson, 535 North Dearborn St., Chicago, Secretary.

Conference of State Secretaries and Editors, Chicago, Feb. 8-9. Dr. Olin West, 535 North Dearborn St., Chicago, Secretary.

American Association of Pathologists and Bacteriologists, Chicago, March 8-9. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland, Secretary.

American Orthopsychiatric Association, New York, Feb. 14-16. Dr. Nina Ridenour, 1790 Broadway, Room 916, New York 19, Secretary.

American Physiological Society, Atlantic City, March 11-15. Dr. Wallace O. Fenn, 260 Crittenden Blvd., Rochester 7, New York, Secretary.

American Society for Experimental Pathology, Atlantic City, March 11-15. Dr. Harry P. Smith, 630 W. 168th St., New York 32, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, March 5-8. Dr. Warren W. Furey, 30 North Michigan Ave., Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, March 18-21. Dr. John G. Young, 1719 Pacific Avenue, Dallas 1, Director of Clinics.

Federation of American Societies for Experimental Biology, Atlantic City, March 11-15. Dr. D. R. Hooker, 19 West Chase Street, Baltimore 1, Secretary.

Medical Library Association, New Haven, Conn., March 25-27. Miss Frida Pliefke, 2000 Medical Arts Bldg., Minneapolis 2, Secretary.

Missouri State Medical Association, St. Louis, March 24-26. Dr. Ralph L. Thompson, 634 N. Grand Blvd., St. Louis 3, Secretary.

National Conference on Medical Service, Chicago, February 10. Dr. Cleon A. Nafe, 822 Hume-Mansur Bldg., Indianapolis 4, Secretary.

Southeastern Surgical Congress, Memphis, Tenn., March 11-13. Dr. Benjamin T. Beasley, 45 Edgewood Ave. S.E., Atlanta 3, Georgia, Secretary.

Washington Letter

(*From a Special Correspondent*)

Jan. 28, 1946.

American Medical Association Accused of Misleading Public

Representative Biemiller, Democrat of Wisconsin, charged that the National Physicians' Committee had misrepresented the Wagner-Murray-Dingell bill to the public. He accused the American Medical Association of exerting pressure on Congress against compulsory health insurance and said that the organization was involved in a double deal in which it appeared to support voluntary health insurance while its "rear guard of expendables," the National Physicians' Committee, supplied "canned" advertisements to newspapers and inspired letters to Congress opposing federal health measures. Representative Biemiller appeared at a conference on a national program sponsored by the District of Columbia chapter of the Physicians Forum headed by Dr. A. T. Rand. Nelson Cruikshank, director of social insurance activities of the American Federation of Labor, also supported the Wagner-Murray-Dingell bill.

Admiral McIntire Writes on Health of Late President

Considerable attention was given here to the signed article in *Collier's* magazine by Vice Admiral Ross T. McIntire, personal physician to the late President Roosevelt, in which he said that the President had regained considerable lost weight and "every cause for anxiety seemed to have been lifted" before his sudden collapse and death last April. Just minutes before the President's collapse, he wrote, he had received an "optimistic" report on the President's health from Commander Howard Bruenn, one of the Navy's "fine internists," who was in personal charge of the President.

Hospital Signs Union Contract for Nonprofessional Workers

Emergency Hospital is the first hospital here to sign a union contract with nonprofessional employees, assuring wage increases up to $7.50 a week and ending a disagreement involving more than three years of litigation. The hospital's refusal to recognize the American Federation of Labor Building Service Employees Union almost resulted in a strike last July.

District Opposes Sharing Medical Center Costs

Commissioners of the District of Columbia have protested in a lengthy report to representative McMillan of the House District Committee against charging the capital for any portion of the proposed 1,500 bed hospital center. Commissioner John Russell Young states that District taxpayers are now paying about nine million dollars annually for the care of the sick.

Child Care Centers to Close February 28

Henry J. Sullivan of the Federal Works Agency has advised that after February 28 no federal funds will be available for child care centers in public buildings. Teachers and officers of child care centers are now endeavoring to arrange operation of the nursery schools on a cooperative basis.

Ninety Thousand Treated in Veterans Hospitals

The Veterans Administration has announced that the number of veterans receiving hospital treatment has passed 90,000 and revealed that progress is being made in recruiting more doctors and nurses under new regulations of the Department of Medicine and Surgery of the Veterans Administration.

Walter Reed Amputees Urge Artificial Limb Foundation

Amputees at Walter Reed Hospital have urged creation of a permanent foundation, financed primarily by private contributions, to aid the physically handicapped. They fear that artificial limb legislation will die as public sympathy wanes toward the nation's 14,000 war amputees. An editorial in the *Service Stripe*, weekly newspaper published by Walter Reed patients, criticized public apathy, which is claimed to have retarded artificial limb research during the past fifty years. A decision has not yet been made by Congress on government sponsored artificial limb research. The House Labor Committee subcommittee on aid to the physically handicapped first urged that such research be centered in the U. S. Public Health Service but later recommended that the Veterans Administration take over the job. The final decision is to speed up pending Congressional action on legislation affecting all government health services.

Typhus Expert Honored for Work in Europe

While the nation's capital launched a program to exterminate rats, 22 per cent of which are reported to be infested with typhus-carrying fleas, Dr. Leonard A. Scheele, senior surgeon of the U. S. Public Health Service, was awarded the Typhus Commission Medal for "exceptionally meritorious service" in preventing the spread of the disease in northwestern Europe during 1944 and 1945. Already 1 child in the capital has been found to be infected with typhus. The medal was presented to Dr. Scheele by Dr. Thomas Parran, surgeon general, in services at the National Institute of Health in Bethesda. The citation with the award was read by Brig. Gen. Stanhope Bayne-Jones, commission director.

Nationalized G. I. Universities Proposed

Educational officials here are studying the proposal made at a meeting of the National Education Association veteran education conference in Cleveland that "G. I. universities" should be set up if present colleges and universities fail to accommodate war veteran students. An estimated 750,000 are expected to enroll by next September. Dr. Alonzo G. Grace, Connecticut commissioner of education, suggests that the federal government "has a responsibility to take over training facilities, including army and navy camps, and establish college and university opportunities for youths." He suggests that nonservice youths attend in order that veterans may have first priority on established colleges.

General Bradley Makes Appointments to New Medical Board

Veterans Administrator Omar N. Bradley has announced the first appointments under the new law creating a department of medicine and surgery in the agency which is not controlled by civil service. The appointment of Major Gen. Paul R. Hawley as acting director was purely "technical," as he has been serving in this capacity. Dr. Robert Webb, veteran of four years' service in the South Pacific, was named chief psychiatrist in the Washington regional office.

Progress in Reorganization of Veterans Administration

High praise for the progress made in reorganization of the medical department of the Veterans Administration was made by Representative Edith Nourse Rogers of Massachusetts in a tribute to Veterans Administrator Omar N. Bradley and Acting Medical Director Paul R. Hawley. She warned that they will continue to need the help and cooperation of the medical profession and the public.

University Offers Intensive Medical Postgraduate Courses

A series of intensive courses in postgraduate subjects will be available to veterans beginning February 11, according to Dr. Walter A. Bloedorn, dean of George Washington University School of Medicine. A grant from the W. K. Kellogg Foundation enables eight courses to be scheduled within allowances of the G. I. Bill of Rights.

Meeting of Hospital Service Plan Commission

The quarterly meeting of the Hospital Service Plan Commission of the American Hospital Association has been held at the Hotel Statler. John R. Mannix, commission chairman and director of the Chicago Blue Cross Plan, presided, and in charge of arrangements was C. Rufus Rorem, commission director.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Social Security

H. R. 5116, introduced by Representative King, California, proposes to amend the Social Security Act to provide for payment for hospital, medical and health services to needy aged persons, to dependent children and to needy blind persons.

Commission for Physically Handicapped

Representative Sparkman, Alabama, has introduced H. R. 5206, to establish a Federal Commission for the Physically Handicapped. This commission, among other things, will be authorized to provide for medical, surgical and therapeutic treatments, the application of prosthetic or orthopedic appliances, hearing aids, eyeglasses and such other devices as may by their use enable physically handicapped persons to become proficient physically so as to be able to earn their own living, wholly or in part. The bill contains a title proposing an appropriation of $2,000,000 to the Public Health Service to be available for research, applied medicine and treatment, and necessary expenses to develop a cure for deafness. The bill indicates that additional titles will be added covering grants to the Public Health Service for clinics on the treatment of poliomyelitis and epilepsy.

Miscellaneous

S. J. Res. 128, introduced by Senator Murdock, Utah, proposes an appropriation of $500,000 to be used by the Administrator of Veterans' Affairs for the purpose of acquiring a site for, and building and equipping, a laboratory to be used in conducting scientific studies of artificial legs and appliances therefor.

Representative Lemke, North Dakota, proposes by H. J. Res. 298 that the veterans' hospital at Fargo, N. D., shall be known as the Clarence Theodore Hoverson Memorial Veterans' Hospital.

H. R. 5181, introduced by Representative Sumners, Texas, would authorize the use of the employees' compensation fund to furnish medical and hospital services to certain enrollees of the Civilian Conservation Corps.

H. R. 5193, introduced by Representative Lemke, North Dakota, proposes that no person shall be employed as an officer or employee of the United States as a pharmacist unless such person holds a degree in pharmacy based on not less than a two year college course in pharmacy or its equivalent.

STATE LEGISLATION

California

Bills Introduced.—A. C. R. 10-X proposes the adoption of a resolution to the effect that, if legislation is enacted establishing a medical school and center at the University of California at Los Angeles, the Board of Regents of the university give favorable consideration to the location of such institution in the San Fernando Valley. A. 88-X and S. 57-X propose to create a State Advisory Council on Hospital Facilities and to authorize the Department of Public Health to make a survey of existing public and private hospitals and health centers in the state, to evaluate the sufficiency of such hospitals and health centers to supply the necessary physical facilities for furnishing adequate hospital, clinic and similar services to the people of the state and to make recommendations for such additional facilities as may be necessary. S. 54-X proposes the appropriation of a sum of money to the California Polytechnic School to be used in part for the planting and cultivating of herbs and plants, the resins, gums and oils of which are used for medicinal purposes.

Bills Passed.—A. 35-X passed the assembly January 15. It proposes to authorize the appropriation to the Regents of the University of California of the sum of seven million dollars for the purpose of establishing, equipping and maintaining a medical school and center as a unit in the University of California at Los Angeles. A. 37-A passed the assembly January 17. It proposes to amend the business and professions code so as to increase the annual tax and registration fees of osteopaths from $5 to $10 for residents and from $2 to $10 for nonresidents.

A. 61-A passed the assembly January 17. It proposes an appropriation of four million dollars to the Regents of the University of California for the purpose of additional construction, improvements and equipment for the medical center of the University of California at San Francisco.

Massachusetts

Bills Introduced.—H. 301, to amend the medical practice act, proposes that all persons who matriculated at the Middlesex University School of Medicine and were duly graduated therefrom on July 24, 1944 and subsequently served as an intern in a hospital shall be eligible for examination and registration as qualified physicians. H. 767 proposes that all veterans of World Wars I and II, their wives and their children under 18 years, shall be given full hospital and medical care. H. 601, to amend the medical practice act, proposes that a state board of osteopathic examination and registration be established for the purpose of examining and registering persons desiring to practice osteopathy. H. 800, to amend the law relating to the practice of physicians in hospitals, proposes that no person registered as a qualified physician shall be refused the right to practice in a hospital supported in whole or in part by contributions from the commonwealth or any hospital endowed for charitable purposes and not operated for profit because said physician is not a member of any particular medical association, society or organization. S. 189, to amend the medical practice act, proposes that all physicians, after the removal of any limb or organ, whether or not written or verbal permission has been given by the patient and whether or not as the result of an accident the patient is unconscious and no near relative can be reached quickly, be required to deliver to the patient a written statement setting forth the nature of the operation which he performed and his reasons for considering such operation necessary. S. 259, to amend the law relating to the furnishing of medical care to recipients of old age assistance, proposes that no board of public welfare or old age assistance bureau shall set a rate of payment for medical services to recipients of old age assistance that is less than the accepted rate for medical services in the community in which the recipient lives, unless the physician is willing to accept a payment for his services less than the accepted rate. S. 263, to amend the medical practice act, proposes that any person who graduated from the Middlesex school of medicine on or before Dec. 31, 1945 and who subsequently served as intern in a hospital shall be eligible for examination and registration as a qualified physician. S. 264 proposes that no person shall be required to submit to vaccination or inoculation of any kind against his will as a condition precedent to admission to or attendance at any public school and that no certificate of vaccination or nonvaccination shall be required as an entrance requirement to attendance by any child in the public schools of the state. S. 386 proposes that the department of mental health be authorized to select and acquire a site for the erection of a state hospital for the treatment and study of persons who have degenerated in health through the excessive use of intoxicating liquors.

New York

Bills Introduced.—A. 94, to amend the education law, proposes the establishment of two medical colleges to be known as New York State Victory Medical College I and New York State Victory Medical College II, one to be located in New York City and one to be located in upstate New York. Each of such colleges shall be initially equipped to provide courses of instruction for four thousand pupils. A. 186, to amend the education law, proposes the establishment of a New York State Victory Medical College, to be initially equipped to provide courses of instruction for four thousand pupils. A. 294, to amend the laws relating to the construction of municipal hospitals, proposes that the city of New York be authorized to select and acquire a site and to erect and equip a public general hospital and dispensary to meet the present inadequate hospital facilities now existing within the city. S. 171, to amend the education law, proposes the establishment of a medical college to be known as New York State Medical College, initially equipped to provide courses of instruction for four thousand pupils. S. 265 and A. 245, to amend the education law, propose that the health service to be rendered to pupils in public schools shall include the necessary facilities to afford adequate physical examinations, including x-raying of the chest of all pupils annually. S. 268 and A. 215, to amend the public health law, propose the enactment of a law providing for a statewide system of health insurance. S. 283 and A. 123 propose that no professional schools shall deny an applicant admission thereto because of race, creed, color or national origin. S. 285 and A. 89, to amend the education law, propose the establishment of an institution to be known as New York State University, which shall include, among other things, a school of medicine. S. 332, to amend the civil practice act, proposes the authorization of the introduction in evidence in a law suit of hospital bills bearing a certification by the superintendent or head of the hospital that the bill is true and correct and that the amount charged therefor is the fair and reasonable value of the services rendered.

Virginia

Bill Introduced.—S. 21 proposes that the state board of health be authorized to initiate and administer a program of hospital treatment and care for indigent persons residing in the state.

CONFERENCE OF STATE SECRETARIES AND EDITORS

The Annuel Conference of Secretaries and Editors of Constituent State Medical Associations will be held in the American Medical Association building in Chicago February 8 and 9. The program will be as follows:

FRIDAY, FEBRUARY 8—10 A. M.

Call to Order. R. L. Sensenich, *Chairman of the Board of Trustees* of the American Medical Association.

Current Status of Medical Legislation. J. W. Holloway Jr., Director, Bureau of Legal Medicine and Legislation.

Discussion: Joseph S. Lawrence, Director, Washington Office of the Council on Medical Service and Public Relations.

Plans for Medical Care in Rural Areas. F. S. Crockett, Chairman, Committee on Rural Medical Service.

Discussion: L. W. Larson, Secretary, North Dakota State Medical Association.

12:30 P. M. Luncheon.

FRIDAY, FEBRUARY 8—2 P. M.

Address. Harrison H. Shoulders, President-Elect of the American Medical Association.

State Plans for Aid to Returning Medical Veterans. George F. Lull, Associate General Manager of the American Medical Association.

Discussion: Victor Johnson, Secretary of the Council on Medical Education and Hospitals, and Robert C. Ayers, Director, War Property Distribution of the Federal Security Administration.

Plan for Furnishing Medical Care to Veterans. Col. James C. Harding, Veterans Administration.

Discussion: L. Fernald Foster, Secretary, Michigan State Medical Society.

FRIDAY, FEBRUARY 8—6:30 P. M.

Dinner Meeting of Editors of State Medical Journals
Palmer House, Crystal Room

Presiding: Lyman W. Mason, Editor, *Rocky Mountain Medical Journal.*

Clinic on Editorial Problems. Henry A. Davidson, Editor, *Journal of the Medical Society of New Jersey.*

SATURDAY, FEBRUARY 9—9:30 A. M.

Public Relations of American Medicine. Morris Fishbein, Editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Discussion: John Hunton, Executive Secretary, California Medical Association, and Edward Stegen, National Physicians' Comittee for the Extension of Medical Care.

Progress Toward a National Medical Prepayment Plan. Jay Ketchum, Executive Vice President, Michigan Medical Service.

Discussion: Edward J. McCormick, Chairman, and A. W. Adson, Member, Council on Medical Service and Public Relations.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education and public health.)

CALIFORNIA

First Evans Lecture.—Dr. Wesley W. Spink, associate professor of medicine, University of Minnesota Medical School, Minneapolis, gave the first annual Newton G. Evans Lecture in bacteriology and pathology at the College of Medical Evangelists, Loma-Linda-Los Angeles, November 29. His subject was "Brucellosis: Diagnostic and Therapeutic Consideration." Dr. Evans, for whom the lecture was named, died December 19 in the White Memorial Hospital. He had been professor of pathology and director of research at the College of Medical Evangelists and formerly served as president of the college and dean of the medical school.

New Department of Medical Physics.—A department of medical physics has been established within the department of physics on the Berkeley campus of the University of California Medical School, to apply the products of the cyclotron to the study of health and disease and for human betterment. Close liaison will be maintained with the medical school and the radiation laboratory, as well as with the department of physics. Because of the war, many men of the science departments still are on leave. However, work in the new department, headed by Dr. John H. Lawrence, will go forward as rapidly as possible. At the present time the staff, in addition to Dr. Lawrence, consists of Dr. Joseph G. Hamilton, assistant professor of medical physics and assistant professor of medicine and radiology, Hardin B. Jones, Ph.D. (physiology) and Cornelius A. Tobias, Ph.D. (physics). The department will be housed in the Donner Laboratory for Medical Physics, a gift of the International Cancer Research Foundation, of which William H. Donner, Philadelphia, is president. It is situated near Crocker Radiation Laboratory, which was built to house the 60 inch cyclotron and is now devoted to medical physics for the most part. Much had been accomplished before the war with radioactive isotopes, such as carbon in the study of photosynthesis, sodium in numerous investigations and phosphorus in the study of plant growth and human health and disease, particularly polycythemia vera, for which it has become an established treatment. A cooperative program is being planned with the university's medical school in San Francisco which Dr. Lawrence believes will lead to important advances in the understanding of the human body in health and disease and to improvements in therapy. Neutron therapy for the treatment of cancer is to be continued and extended. The fall semester, which began in October 1945, marked the offering of one upper-division course entitled medical physics. This course gives an introduction to nuclear and radiation physics, electronics, biologic effects of radiations and an introduction to the tracer technic. Four additional upper-division courses are planned for the spring semester: an introduction to medical physics, photobiology, laboratory courses in medical physics, and medical physical aspects of aviation. Two degrees are planned, a Ph.D. in medical physics for students who have earned the M.D. and a Ph.D. in biophysics for others. These degrees will require the completion of a minimum number of courses in the fields of physics, chemistry, physiology, mathematics and medicine, to give a well balanced basic medical physics background, and completion of a certain amount of original research in the laboratory.

DISTRICT OF COLUMBIA

New Mental Hygiene Head.—Dr. Leopold E. Wexberg, New Orleans, has been appointed chief of the bureau of mental hygiene of the District health department. Dr. Wexberg came to the United States in 1933 after nineteen years of practice in Vienna. He succeeds Dr. John F. Owen, who resigned (The Journal, June 23, 1945, p. 604).

Stephen McDonough Goes to Minnesota.—Stephen J. McDonough Jr., Washington science editor of the Associated Press from 1933 to 1942, when he entered military service, has joined the staff of *Modern Medicine*, Minneapolis. Until his recent discharge as major in the medical administrative corps, Mr. McDonough served as chief of the planning board, technical information division, Office of the Surgeon General of the Army, and as a member of the committee on information of the division of medical sciences of the National Research Council. Mr. McDonough is a former secretary of the National Association of Science Writers.

ILLINOIS

Changes in Health Personnel.—Dr. James W. Chapman, Charlevoix, Mich., has been appointed director of the DuPage County Health Department, with headquarters in Villa Park, to succeed Dr. Sidney I. Franklin, it is reported.——Dr. Walter C. Wilhelmj, East St. Louis, has been appointed acting director of the East Side Health District, succeeding the late Dr. Robert C. Farrier.——Dr. Emil J. Bunata, who was recently released from military service, has returned to his position as health officer of Berwyn, the position he held when he entered military service in 1942.

Chicago

Health Educational Program.—The Mount Sinai Hospital on January 22 opened a series of meetings for the general public to disseminate information on how to maintain and enjoy good health. The meetings are to be conducted as forums where opportunities will be given to the public to ask questions and will be followed by a social period.

James Case Chosen President of Battle Creek Sanitarium.—Dr. James T. Case was elected president of the new board of the Battle Creek (Mich.) Sanitarium. The sanitarium and the Seventh Day Adventists General Conference recently settled a two year litigation with a compromise agreement. The operation of the Battle Creek and Benevolent Association is one of the results of the new setup (The Journal, Dec. 1, 1945, p. 971).

Dinner for Returning Faculty Members.—The faculty of medicine of Northwestern University Medical School, under the auspices of the medical division of the Alumni Association, will hold a dinner February 7 at the Furniture Club of America, 666 Lake Shore Drive. The event is in honor of members of the faculty who have served in the armed forces and will begin with cocktails at 5 p. m. and dinner at 7. Two hundred and fifteen members of the faculty served in various military divisions, most of whom have returned. Any member who has not received an invitation is urged to communicate with the Medical Alumni Office, 303 East Chicago Avenue. The telephone number is Superior 4500, extension 212.

Branch Meetings.—The North Side Branch of the Chicago Medical Society will be addressed February 7 by Dr. Max M. Peet, professor of neurologic surgery, University of Michigan Medical School, Ann Arbor. His subject will be "Surgical Treatment of Hypertension and Peripheral Vascular Disease." The North Shore Branch will hold a meeting at the Edgewater Beach Hotel, February 5. "Do's and Don'ts" will be discussed by the following in the respective subjects:

Dr. Harry Culver, Acute Urinary Retention.
Dr. Ovid O. Meyer, Madison, Wis., Relation to Anticoagulants.
Dr. Harry A. Oberhelman, "Acute" Abdomen.
Dr. Arthur R. Colwell, Evanston, Ill., Diabetic Coma.
Dr. Erwin R. Schmidt, Madison, Wis., Acute Intestinal Obstruction.

LOUISIANA

Personal.—Dr. Boni J. De Laureal was recently elected treasurer of the Orleans Parish Medical Society to succeed Dr. Paul G. Lacroix, who resigned because of ill health, both of New Orleans.

Grant for Hypertension.—The Winthrop Chemical Company has made a grant of $2,500 to the Alton Ochsner Medical Foundation for research in hypertension. The chemical phases of this problem are directed by Otto Schales, D.Sc., New Orleans.

Orientation Course in Allergy.—The American Academy of Allergy, under the sponsorship of the Louisiana State University School of Medicine, will give a five day orientation course in allergy in New Orleans, March 8-12, with headquarters at the Roosevelt Hotel. Inquiries should be addressed to the Dean's Office, Louisiana State University School of Medicine, 1542 Tulane Avenue, New Orleans 13.

MARYLAND

Anesthesiology Service Launched at University Hospital.—On January 1 the regular course of instruction in anesthesiology of the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, was augmented by the establishment of a separate service of anesthesiology in the University Hospital, the principal clinical teaching unit of the school of medicine.

DeLamar Lecture in Hygiene.—Dr. Willard F. Machle, formerly associate director, Kettering Research Institute, Cincinnati, and recently director, Armored Medical Research Laboratory, Fort Knox, Ky., gave the DeLamar Lecture in Hygiene at the Johns Hopkins University School of Hygiene and Public Health, Baltimore, January 8, on "Interrelationship Between Man, His Environment and Tasks."

Personal.—John E. Ransom has resigned as assistant director of Johns Hopkins Hospital, Baltimore, to become director of a survey of state hospitals in Georgia. The survey is under the auspices of the Georgia State Health Department and will involve the study of existing hospital facilities in Georgia for proposed expansion. Mr. Ransom is a former superintendent of the Toledo Hospital, Toledo, Ohio, and in 1941 served as executive secretary of the Hospital Council of Greater New York, according to the *Modern Hospital.*——R. Dale Smith, head of the department of biology at Gonzaga University, Spokane, Wash., has accepted the position of assistant professor with the department of anatomy of the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, beginning January 1, according to Dr. Robert U. Patterson.

MICHIGAN

Course in Occupational Health Postponed.—A twelve week orientation course in occupational health and medicine offered by the School of Occupational Health, Wayne University, Detroit, scheduled to begin March 4, has been canceled on account of the existing situation, which has closed so many industrial plants in which practical instruction was planned. A course will be offered at a later date to be announced when conditions permit.

Review Course for Physicians.—The University of Michigan Medical School, Ann Arbor, announces that review courses for returning medical officers and civilian physicians will be conducted at the university as follows: internal medicine, March 4-April 27; course for practitioners, April 29-June 22, and brief review courses in anatomy, internal medicine, allergy, cardiology, blood diseases, endocrinology and metabolism, therapeutics, gastroenterology, ophthalmology and otolaryngology, pediatrics and roentgenology in April, May and June. Requests for information should be addressed to Dr. Howard H. Cummings, chairman, Department of Postgraduate Medicine, University Hospital, Ann Arbor.

Change in Executive Administration.—A change in the executive committee of the University of Michigan Medical School, Ann Arbor, has been approved by the board of regents. Under the new plan the executive committee will consist of the dean of the medical school, the director of the University Hospital and four additional members of the executive faculty to be appointed by the board of regents on recommendation by the president of the university. The appointed members are to consist of a representative from each of two clinical departments and a representative from each of two preclinical departments. Previously there had been no provision for apportioning membership between the departments. The new plan had received approval of the medical school's executive committee and executive faculty before final approval was given by the board of regents.

MINNESOTA

New Professorship in Public Health.—The first permanently endowed professorship in the University of Minnesota Medical School, Minneapolis, was created recently as the Mayo Professorship in Public Health when the board of regents accepted endowment of that chair by the Mayo Properties Association. To pay the salary, which will not exceed $10,000, a gift of $150,000 was made to the university by the Mayo Properties Association, which specified that over and above the income from that sum the total will be made up from the income of the Mayo Foundation for Medical Education and Research. Dr. Harold S. Diehl, dean of medical sciences, said he thought appointment to the new chair would be made before July 1, when the next fiscal year begins. One other named professorship, the George Chase Christian professorship in cancer research, exists at the university but is not permanent, although it is still supported by gifts made when the Citizens Aid Society was liquidated. The school of public health was created in the medical school about two years ago when Dr. Diehl recommended that the then department of [illegible] the medical school, like the school of nursing. Dr. Gaylord W. Anderson has been head of the school from the first, although during the war he has been on leave as head of the division of medical intelligence in the Office of the Surgeon General, War Department. The Mayo Properties Association is the organization formed by the late Drs. Charles H. and William J. Mayo and their associates to hold and manage the assets of the Mayo Clinic. The Mayo Foundation for Medical Education and Research is an educational division of the University of Minnesota on the graduate level. It was first endowed with $2,000,000 in 1917, which sum was subsequently increased by $500,000 in 1934. It carries a broad program of graduate teaching, maintains laboratories and will now contribute to the new professorship. The school of public health was described by Dr. Diehl as one of six regional training centers in this country having as a principal function the training on the graduate level of doctors, engineers and nurses in public health matters to become specialists. For ten years past the school has had federal support of about $15,000 a year. Columbia, Harvard, Yale, Johns Hopkins and Michigan are other institutions which have such schools. Minnesota was designated a regular public health training center after the state health officers of the North Central group of states expressed a desire to have the federal government take that action.

NEW YORK

James Perkins Named Deputy Health Commissioner.—Dr. James E. Perkins, Delmar, director of the division of communicable disease, New York State Department of Health, was on January 7 appointed deputy health commissioner, succeeding Dr. Paul B. Brooks, who retired January 1 (The Journal, January 19, p. 163). Dr. Hollis S. Ingraham, Kingston, was named acting director of the division of communicable disease. Dr. Perkins recently returned after several months in Italy as an officer in the U. S. Public Health Service.

Cerebral Palsy Group Backs Local Project.—The Cerebral Palsy Association, formed by a group of parents in Rochester, voted at a meeting January 9 to support the project at Strong Memorial Hospital and the Rochester Municipal Hospital for the care of children with cerebral palsy (The Journal, Dec. 22, 1945, p. 1216). The Cerebral Palsy Association comprises about 95 parents of children afflicted with the disease. Lawrence Ross, previously chairman pro tem of the association, was named chairman at the meeting and Mrs. Herbert Soule, wife of Dr. Herbert C. Soude Jr., instructor in pediatrics at the University of Rochester School of Medicine and Dentistry, was named secretary. There are said to be about 300 children in Rochester affected with cerebral palsy. The parents who banded together originally planned to obtain funds to provide a spacious building for the care of these children.

New York City

Physician Chosen Princeton Board Member.—Dr. Fordyce Barker St. John has been elected a member of the board of trustees of Princeton University, Princeton, N. J. Dr. St. John graduated at Princeton in 1905 and at Columbia University College of Physicians and Surgeons in 1909, serving there currently as professor of clinical surgery.

Blood Transfusion Grants.—The Blood Transfusion Association of New York will resume grants-in-aid for research in the field of blood and blood substitutes in relation to transfusions. Those interested in obtaining such grants should write, giving full information concerning their projects, to Chairman, Research Grants Committee, 2 West 106th Street.

Hepatic Disorders.—On February 7 the New York Academy of Medicine will devote a meeting to the discussion of hepatic disorders, with Drs. Franklin M. Hanger Jr. speaking on "The Uses and Limitations of Liver Function Tests" and Allen O. Whipple and Arthur H. Blakemore on "Indications for Shunting Operations Determined by Pathologic Findings."

Judd Prize Goes to Allen Whipple.—The annual Judd Award of the Memorial Hospital for Cancer and Allied Diseases will be presented to Dr. Allen O. Whipple, professor and executive officer of the department of surgery, Columbia University College of Physicians and Surgeons, the New York *Times* announced January 17. Dr. Whipple was nominated for the award for having made the "greatest advancement to the discovery of a cure for cancer." The citation noted Dr. Whipple's special achievements in surgery in the field of cancer relating to the duodenum and pancreas, adding that his method "has established entirely new and successful opportunities for [illegible] ure of a group of cancers previously deemed hopeless." The Judd award was established in 1937 under the will of Katherine Berkan Judd, who died in 1934 and left a trust fund to provide an annual prize of $1,000 to encourage research in the causes and cure of cancer.

"Dean's Committee" to Recruit Doctors for Veterans' Hospitals.—Announcement was made January 5 of a "deans' committee," representing all five medical colleges in New York City, to cooperate with the Veterans Administration in the recruitment of physicians for veteran's hospitals. The New York City committee consists of Dr. Willard C. Rappleye, dean of the Columbia University College of Physicians and Surgeons, chairman; Dr. Jean A. Curran, president and dean of the Long Island College of Medicine, Brooklyn; Dr. J. A. W. Hetrick, president and dean of the New York Medical College, Flower and Fifth Avenue Hospitals; Joseph C. Hinsey, Ph.D., dean of the Cornell University Medical College, and Dr. Donal Sheehan, acting dean of the New York University College of Medicine. Anticipating recent enactment of a law creating a bureau of medicine and surgery in the Veterans Administration, the medical colleges set up the committee some time ago to work out methods of administration with Col. Harvey C. Hardegree, manager, and Col. John G. Hood Jr., clinical director, of the 2,000 bed Kingsbridge Veterans Hospital in the Bronx. The committee is empowered to nominate the professional staff at the hospital. A number of fifteen to twenty senior consultants from a list of leading New York specialists is to be nominated, this group to be supplemented later with about one hundred consultants to act as attending or visiting physicians, mostly on part time duty, and from sixty to eighty resident physicians on full time duty. The Kingsbridge Hospital now has 119 full time medical officers, some of whom will remain on full time or part time duty, while others will be assigned to other veterans' hospitals.

SOUTH CAROLINA

Dr. Ball Returns to State Position.—Dr. Robert W. Ball, Columbia, recently released from the army, has returned to his position as director of the division of maternal and child welfare of the South Carolina State Department of Health. Dr. Hilda Sheriff, Columbia, who served as director of the division in the absence of Dr. Ball, will become associate director.

Personal.—Dr. Mauldin J. Boggs, Abbeville, who has been health officer of McCormick and Greenwood counties, with headquarters at Greenwood, has been appointed health officer for Abbeville County, with offices in Due West.——Dr. Joseph Decherd Guess, Greenville, has been named editor of the Bulletin of the Greenville County Medical Society to succeed Dr. James W. Jervey, Greenville, resigned.——Dr. and Mrs. Robert Wilson, Charleston, observed their fiftieth wedding anniversary November 27.

New Head of Physiologic Chemistry.—Dr. William M. McCord, formerly associate professor of physiologic chemistry, Louisiana State University School of Medicine, New Orleans, has been appointed professor and head of the department of physiologic chemistry of the Medical College for the State of South Carolina. At a special meeting of the house of delegates of the South Carolina Medical Association and other members in Columbia, S. C., January 3, unanimous approval was given the construction program of the medical college. This includes a teaching hospital under ownership and operation by the medical school in addition to hospital teaching facilities provided by the Roper Hospital, with which a cooperative agreement has been established. A committee consisting of members from each county was established by the association to promote the medical college program.

TEXAS

Psychopathic Hospital Reopened.—The Galveston State Psychopathic Hospital, a unit of the University of Texas Medical Branch, Galveston, under the direction of Dr. Jack R. Ewalt, professor of neuropsychiatry, has reopened for the diagnosis and management of acute cases of mental disorder. The hospital was formerly under the direction of the state board of control but was transferred to the university by legislative action (The Journal, June 9, 1945, p. 454). Its bed capacity has been increased from 80 to 120. The hospital furnishes special facilities for teaching and research in neurology and psychiatry.

Medical Service Society Honored.—The Medical Society of Dallas was guest at a luncheon, December 15, given by the Southwestern Medical Foundation in recognition of its "service in medicine" in Dallas. The group, which represents the pharmaceutical houses in the area, was presented with a bronze plaque. The Medical Service Society of Dallas, whose membership is made up of representatives of various pharmaceutical houses in America who live in Dallas, was formed about two years ago. The Dallas chapter has adopted the medical library of the Southwestern College as a project and has been active in its development. The *Dallas Medical Journal* states that other chapters of the society are being organized, with some units already operating in Houston and Fort Worth.

UTAH

Activities at Utah Medical School.—Dr. Scott M. Smith has been named assistant clinical professor of anesthesiology and acting head of the newly established department of anesthesiology at the University of Utah School of Medicine, Salt Lake City. Gustave Albin Matson, Ph.D., who has been on active duty in the U. S. Sanitary Corps since 1942, has returned to his position at the university as associate professor of bacteriology. New appointments at the school include:

Dr. Randolph T. Shields, formerly resident in surgery at the University of Pennsylvania and more recently major in the U. S. Army Medical Corps in the China-Burma-India Theater, instructor in surgery.

Dr. Crichton McNeal, now stationed at the Army Institute of Pathology, Washington, D. C., instructor in pathology.

Dr. David W. Morgan, now at the Regional Hospital, Camp Swift, Texas, clinical instructor in psychiatry.

The Abbott Laboratories of North Chicago has made another grant of $1,500 to the department of pharmacology for the continuation of research on anticonvulsant and other drugs. The Amalgamated Sugar Company of Ogden has donated $300 to assist in remodeling Dr. Matson's research laboratory in the department of bacteriology. The Givaudan-Delawanna Corporation has granted to Dr. Philip B. Price, professor and head of the department of surgery, $5,250 for the investigation of skin disinfection. The Utah Medical Foundation has contributed $500 to the school of medicine for the purchase of books and journals for the medical library.

VIRGINIA

Health Council Formed.—Representatives of thirty-seven organizations interested in public health and medical care at a meeting in Richmond recently decided to establish a statewide health and medical care council and named a committee to work out details of the organization. W. T. Sanger, LL.D., president of the Medical College of Virginia, Richmond, will serve as chairman of the committee.

Dr. DeJarnette Leaves State Service.—Dr. Joseph S. DeJarnette, physician in charge of the DeJarnette Sanitarium, Staunton, has resigned, concluding fifty-six years' service to the state, according to *Southern Medicine and Surgery*. Dr. DeJarnette in 1939 was honored by the staff of the hospital for his completion of fifty years on the hospital staff. He graduated at the Medical College of Virginia, Richmond, in 1888 and began his career at the hospital as third assistant physician. He became superintendent in 1906. In 1928 he founded the DeJarnette Sanitarium, which is a unit of the Western State Hospital.

Gift to Medical School.—Dr. Charles S. Venable, chief surgeon of the Nix Hospital, San Antonio, Texas, has given the University of Virginia Department of Medicine, Charlottesville, $1,500 in war bonds in support of a lectureship in traumatic surgery which he established three years ago (The Journal, April 29, 1944, p. 1310). In the fall of 1942 Dr. Venable turned over to the university his royalty rights for an adjustable splint of his own invention to set up a lectureship as a memorial to his father, the late Charles S. Venable, who was for many years a member of the university faculty as professor of mathematics.

PUERTO RICO

Public Health Meeting.—The Public Health Association of Puerto Rico will hold its fifth annual meeting February 6-9 at the School of Tropical Medicine, San Juan. Among the speakers will be:

Dr. Milton J. Rosenau, Chapel Hill, N. C., president-elect, American Public Health Association.

Dr. John R. Heller Jr., Washington, chief, venereal disease division, U. S. Public Health Service.

Dr. Julio Bustos, chief, Social Health Department, Santiago de Chile.

Margaret Merrell, Sc.D., associate professor of biostatistics, Johns Hopkins University School of Hygiene and Public Health.

John M. Hepler, C.E., director, bureau of sanitary engineering, Michigan Department of Health, Lansing.

One session will be addressed by Gov. Rexford G. Tugwell, Hon. Luis Munoz Marin, president of the Senate, and Dr. Antonio Fernos Isern, commissioner of health of Puerto Rico.

GENERAL

Course for Pathologists.—The postwar educational planning board of the American Society of Clinical Pathologists, of which Dr. Robert A. Moore, St. Louis, is chairman, announces a postgraduate refresher course for pathologists returning from military service, to be held at the Drake Hotel, Chicago, March 2-5.

Conference on Proposed U. S. P. XIII Standards.—Following the pharmacopeial policy in recent revisions, an open U. S. P. conference has been arranged. Any one who is interested in the proposed new or revised standards is invited to present comments or suggestions looking to improvements in proposed U. S. P. standards as released in proofs and circulars. The conference will be held at the Hotel Pennsylvania, New York, starting on February 15. It will continue throughout the day and evening and probably on the following day, February 16. E. Fullerton Cook, Pharm.M., is chairman of the U. S. P. committee of revision.

Citizens Planning Committee for Health.—The Citizens Planning Committee has been organized by the National Health Council, 1790 Broadway, New York, to provide leadership in a movement to coordinate the work of some twenty thousand voluntary health agencies in the country. The committee comprises twenty-five leaders in public service and will work with the professional board of the council. Louis I. Dublin, Ph.D., New York, second vice president of the Metropolitan Life Insurance Company, is temporary chairman. The committee will formulate a plan to strengthen the National Health Council with new executive direction and a unified health education and fund raising program.

Training for Pediatricians.—The American Academy of Pediatrics has received a grant of $10,000 from Mead Johnson and Company to launch a program of placing physicians training in pediatrics available for physicians coming out of the armed services. The program, which is not confined to members of the academy, will include a recommendation for refresher courses, and for residencies that are vacant and other advanced positions. Facilities have been set up in the office of the secretary of the American Academy of Pediatrics, Dr. Clifford G. Grulee, 636 Church Street, Evanston, Ill. The creation of the service stemmed from a survey made by a committee on postwar planning and postwar courses of the academy, of which Dr. Irvine McQuarrie, Minneapolis, is chairman.

Special Society Elections.—At the annual meeting of the American Therapeutic Society at the Netherland Plaza Hotel, Cincinnati, November 11-12, Dr. Joseph F. Borg, St. Paul, was elected president; Drs. William Bryant Rawls, New York, Lucien A. LeDoux, New Orleans, and Nathan S. Davis III, Chicago, vice presidents; Dr. Oscar B. Hunter, Washington, secretary, and Dr. Daniel L. Sexton, St. Louis, treasurer.——Dr. Thomas L. Lee, Kinston, N. C., was elected president of the Seaboard Medical Association at its meeting in Virginia Beach, Va., December 13. He succeeds Dr. Antonio A. Burke, Norfolk, Va. Other officers include Dr. Clarence P. Jones Jr., Newport News, Va., first vice president, and Dr. Clarence P. Jones Sr., also of Newport News, who was reelected for his thirty-eighth consecutive term as secretary-treasurer.

Grants of the Commonwealth Fund.—Recent appropriations of the Commonwealth Fund, New York, include $304,000 for public health activities in Tennessee, Oklahoma and Mississippi, $204,000 for medical research and $121,000 for medical education. Among the research grants were one for the study of arthritis at the Harvard Medical School, Boston, and another for research in kidney and vascular physiology, with special reference to hypertension, at the New York University College of Medicine. A grant of $57,000 was made to Cornell University Medical College, New York, to establish a new clinic where physicians can be trained in a broader medical service than is now available, and $40,000 was granted to the Medical College of Virginia, Richmond, to initiate postgraduate educational services in eastern and southeastern Virginia. The Commonwealth Fund fellowships for British students, first offered in 1925 and interrupted in 1941 by the war, will be resumed next spring, when the British committee of award will be invited to nominate twenty fellows for 1946.

John Hubbard Named Director of Child Health Study.—Dr. John P. Hubbard, instructor of pediatrics (on leave), Harvard Medical School, and in charge of the cardiac clinic of the Children's Hospital, Boston, has been appointed director of a study of child health services of the American Academy of Pediatrics. Dr. Hubbard is directing the project under the auspices of a specially appointed committee of nine members on the study of child health service of the academy in cooperation with the U. S. Public Health Service and the U. S. Children's Bureau. Working with Dr. Hubbard are Drs. Katherine Bain, Washington, D. C., representing the U. S. Children's Bureau, and Charles L. Williams Jr., Wadesboro, N. C., representing the U. S. Public Health Service, both of whom are serving as field directors. Dr. Joseph Lachman, also on loan from the U. S. Public Health Service, is serving as executive secretary of the study in North Carolina, where the national project was launched (The Journal, Dec. 8, 1945, p. 1036). Dr. Hubbard, who was recently released from military service, will have headquarters for the national study in the Children's Hospital, Washington.

Gastroenterological Association Creates Prize.—The National Gastroenterological Association announces the establishment of an annual cash prize award of $100 and a certificate of merit for the best unpublished contribution on gastroenterology or allied subjects. Certificates will also be awarded those physicians whose contributions are deemed worthy. Contestants residing in the United States must be members of the American Medical Association. Those residing in foreign countries must be members of a similar organization in their own country. The winning contribution will be selected by a board of impartial judges, and the award is to be made at the annual convention banquet of the National Gastroenterological Association to be held at the Hotel Pennsylvania, New York, June 20. Certificates awarded to other physicians will be mailed to them. The decision of the judges will be final. The association reserves the exclusive right of first publishing the winning contribution and those receiving certificates of merit in its official publication, the *Review of Gastroenterology*. All entries for the 1946 prize should be limited to 5,000 words, be typewritten in English, be prepared in manuscript form, be submitted in five copies, be accompanied by an entry letter and be received not later than May 1. Entries should be addressed to the National Gastroenterological Association, 1819 Broadway, New York 23.

Science Writing Award Fund.—On January 14 the American Association for the Advancement of Science announced the establishment of the George Westinghouse Science Writing Award Fund to give national recognition to newspaper writers and newspapers contributing most to better popular understanding of the achievements of science and technology. It was stated that the fund had been provided by the Westinghouse Educational Foundation, which is supported by the Westinghouse Electric Corporation in commemoration of the hundredth anniversary of the birth of George Westinghouse. The fund will be administered by the American Association for the Advancement of Science to develop closer cooperation between scientists and news writers in keeping the public informed of scientific developments which more and more affect human lives in this atomic age. In addition to encouraging news writers of press associations as well as newspapers themselves to cultivate general sources of science news in their communities and the marshaling of the 27,000 scientist members of the American Association for the Advancement of Science to this end, the fund provided two annual awards: a cash award of $1,000 to a newspaper writer for outstanding science reporting of the year and a citation to the newspaper whose science news coverage in the preceding year is adjudged most complete and authoritative and most interestingly presented. There may also be awarded at the direction of the awards committee special citations in recognition of distinguished service in science journalism. The first annual awards, covering the year 1946, will be made at the winter meeting of the American Association for the Advancement of Science in December 1946. Details of the judging and presentation of awards will be made at the spring meeting of the association in St. Louis, March 27-31.

CORRECTION

Trichinosis.—In the article on "An Effective Method for the Control of Trichinosis in the United States" (The Journal, Dec 29, 1945), by Dr. S. E. Gould, there was an omission in the fourth sentence of the second paragraph in the right hand column on page 1254. This sentence should read "It has also been found that raw pork in commercial quantities may be rendered free of infective trichinae by lowering its temperature to minus 35 C. (minus 31 F.) or below and holding it at that temperature for two hours or by freezing at minus 17.8 C. (0 F.) for seventy-two hours."

Deaths

Newton Gurdon Evans ⊕ Los Angeles; Cornell University Medical College, New York, 1900; born in Hamilton, Mo., June 1, 1874; taught pathology for a short while at the old American Medical Missionary College in Battle Creek, Mich., moving to the University of Tennessee College of Medicine, Nashville, where he taught pathology until 1911; joined the College of Medical Evangelists, where he became president and professor of pathology in 1914, serving as professor and head of the department until the time of his death, member of the board of trustees, vice president from 1931 to 1936, dean from 1927 to 1931 and again for one year beginning in June 1944; chairman of the board of the Alumni Research Foundation, College of Medical Evangelists; for many years pathologist and director of the laboratory of the Los Angeles County Hospital; specialist certified by the American Board of Pathology, Inc.; fellow of the American College of Physicians and the American Association for the Advancement of Science; member of the Los Angeles Pathological Society and in 1929 president, Los Angeles Cancer Society, president in 1936, American Association of Pathologists and Bacteriologists, American Society of Clinical Pathologists and the Los Angeles Academy of Medicine; retired lieutenant colonel in the medical reserve, serving as commanding officer of the U. S. General Hospital number 47 from 1926 to 1932 and from 1935 to 1937; one of the counselors of the Surgeon General's Library; on Jan. 30, 1945 his portrait was presented to the White Memorial Library; introduced cooperative plan of education in medicine; died in the White Memorial Hospital December 19, aged 71, of carcinoma.

Sumner Marcy Miller ⊕ Peoria, Ill.; Northwestern University Medical School, Chicago, 1899; born in Farmer City, Ill., in 1873; since 1938 health officer of Peoria; president of the Illinois Public Health Association, of which he had been a founder; past president of the Peoria Medical Society; fellow of the American Public Health Association; a founder and for many years president of the Peoria County Tuberculosis Association; founder and first president of the Peoria County chapter of the American Red Cross, which he organized at the outbreak of World War I; later served as a captain in the medical corps of the U. S. Army; a director of the Visiting Nurses Association; a member and past president of the staff of the Methodist Hospital; served on the staff of the Peoria Municipal Tuberculosis Sanitarium; president of the Peoria X-Ray Laboratory; in 1941 received the Northwestern University award of merit for achievement in public health work; as the result of the advancements during his commissionership the city received a health honor roll plaque for the first place among cities under 150,000 from the American Public Health Association and from the United States Chamber of Commerce in 1943 and again in 1944; died December 14, aged 72, of carcinoma of the sigmoid.

Julian Mayo Cabell ⊕ Lieutenant Colonel, U. S. Army, retired, Washington, D. C.; born in Richmond, Va.; Dec. 21, 1860; University of Virginia Department of Medicine, Charlottesville, 1886; entered the U. S. Army as an assistant surgeon in 1887; retired as a captain on March 29, 1897 for disability in line of duty; returned to active duty from May 1914 to December 1914 and from June 24, 1917 until he retired as a major in September 1919; retired with the rank of lieutenant colonel on June 21, 1930 under a special act of Congress; held the Legion of Honor and Purple Heart; served in the Spanish-American War and the Philippine Insurrection; surgeon on the hospital ship *Maine* during the Boer War; served during World War I; at one time superintendent of the Columbia Hospital for Women; died in the Walter Reed General Hospital November 15, aged 84, of carcinoma.

Clyde Madison Speck ⊕ New Albany, Miss.; Vanderbilt University School of Medicine, Nashville, Tenn., 1912; served as associate in psychiatry at the University of Mississippi School of Medicine, University; fellow of the American College of Surgeons; past president and vice president of the Mid-South Postgraduate Medical Assembly; vice president of the state medical association in 1933 and president of the North Mississippi Medical Society in 1939; served during World War I; formerly medical superintendent of the Mississippi State Hospital in Whitfield; helped found the New Albany Hospital, where he died November 9, aged 58, following an appendectomy.

Ludwig Silverman Simon ⊕ Los Angeles; College of Physicians and Surgeons, medical department of Columbia College, New York, 1894; an Affiliate Fellow of the American Medical Association; emeritus member of the Illinois State Medical Society; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; fellow of the American College of Surgeons; formerly president of the medical staff and head of the department of obstetrics at the Michael Reese Hospital, Chicago; died in the Cedars of Lebanon Hospital October 7, aged 74, of uremia, arteriosclerotic heart disease and prostatic hypertrophy.

Vernon Scott Lilly ⊕ Detroit; Ohio State University College of Medicine, Columbus, 1924; fellow of the American College of Surgeons; served during World War I; formerly industrial surgeon for the Parke-Davis Company; on the courtesy staffs, Woman's, St. Joseph's Mercy, Cottage, Florence Crittenton, Charles Godwin Jennings and East Side General hospitals; interned at St. Mark's Hospital in Cleveland and the Harper Hospital, where he served a residency, as assistant surgeon to outpatient department, division of surgery, and where he died September 27, aged 47, of coronary thrombosis.

Benjamin Trowbridge Tilton ⊕ New York; Albert-Ludwigs Universität Medizinische Fakultät, Freiburg, Baden, Germany, 1893; an Affiliate Fellow of the American Medical Association; fellow of the American College of Surgeons; served as director of surgery at the Broad Street Hospital; for many years president and chief of the surgical service at St. Mark's Hospital, where he established a scholarship for nurses; consulting surgeon to the Lincoln and Manhattan State hospitals; died in Black Point, Conn., September 23, aged 77, of heart disease.

Charles William Rodgers Jr., Alexandria, Va.; University of Virginia Department of Medicine, Charlottesville, 1930; interned at the Gallinger Municipal Hospital and formerly resident physician at the George Washington University Hospital in Washington, D. C., where he was associated with the National Airport; member of the American Medical Association; formerly health officer, and on the staff of the King's Daughters' Hospital, Staunton; on the staff of the Alexandria Hospital, where he died October 9, aged 41, of subarachnoid hemorrhage and bronchopneumonia.

Luther Lefever Ames, Wichita, Kan.; College of Physicians and Surgeons, Keokuk, Iowa, 1880; died October 8, aged 94, of coronary occlusion followed by cerebral embolism.

Frank J. Austin, Laceyville, Pa.; University of Nashville Medical Department, 1910; member of the American Medical Association; died September 29, aged 81, of coronary thrombosis.

Francis Herbert Battey, Iowa City; Kansas Medical College, Topeka, 1893; died September 3, aged 79, of carcinoma of the prostate.

Martin Luther Bearden, Memphis, Tenn.; Memphis Hospital Medical College, 1909; member of the American Medical Association; died in the Baptist Memorial Hospital October 27, aged 63, of circulatory failure.

L. V. Bishop, Lancaster, S. C.; Baltimore Medical College, 1893; died October 9, aged 74.

James Alexander Boon, New York; Bellevue Hospital Medical College, New York, 1888; for many years a member of the U. S. Narcotic Bureau; died October 20, aged 79.

Henry Thomas Brogan, West Allis, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1903; died in St. Joseph's Hospital, Milwaukee, October 9, aged 69, of arteriosclerosis and interstitial obstruction.

John Buckley ⊕ Chicago; Illinois Medical College, Chicago, 1906; died October 29, aged 69, of acute dilatation of the heart and chronic myocarditis.

Alanson Capehart, Roxobel, N. C.; Bellevue Hospital Medical College, New York, 1887; served as bank president; died October 11, aged 80, of coronary thrombosis and arteriosclerotic heart disease.

Enos Ralph Cheney, Gypsum, Kan.; Kansas City (Mo.) Medical College, 1891; honorary member of the Kansas Medical Society; served in the medical corps of the U. S. Army during World War I; for many years served on the local school board, most of the time as director, and on the city council; died in a hospital at Wichita October 9, aged 74.

Roy William Chivers, Jackson, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1900; member of the American Medical Association; served as health officer and president of the board of health; on the staff of the W. A. Foote Memorial Hospital; died October 25, aged 67, of coronary occlusion.

Robert William Cotton ⊕ Bellevue, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1906; served during World War I; company surgeon for the Pittsburgh and Lake Erie Railroad Company; died in Baltimore October 14, aged 68, of coronary heart disease.

Richard F. Crabtree, Gamaliel, Ky.; Vanderbilt University School of Medicine, Nashville, Tenn., 1882; member of the American Medical Association; on the staff of the T. J. Samson Community Hospital in Glasgow; died October 17, aged 87, of chronic myocarditis.

William McKee Crosier ⊕ Alexis, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; past president of the Warren County Medical Society; served as a member of the local school board and of the Warren County library board; on the staffs of the St. Mary's and Cottage hospitals in Galesburg and the Monmouth Hospital in Monmouth, where he died October 27, aged 69, of heart disease.

Burnham C. Dale, Marion, Ind.; Medical College of Indiana, Indianapolis, 1893; member of the American Medical Association; county coroner; member of the board of directors of the Emily Flynn Home for the Aged; died October 26, aged 74, of coronary occlusion.

Francis Peter Daly, Chippewa Falls, Wis.; Rush Medical College, Chicago, 1897; member of the American Medical Association; deputy state health officer; died in Rochester, Minn., October 15, aged 76, of ileocolitis and carcinoma of the colon.

Magnet Jervais Davis, Los Angeles; Cincinnati College of Medicine and Surgery, 1896; died October 25, aged 79, of generalized arteriosclerosis.

Maxwell Dorr, Brooklyn; Long Island College of Medicine, Brooklyn, 1932; member of the American Medical Association; began active duty as a first lieutenant in the medical corps, Army of the United States, in October 1942; service terminated in August 1943; on the courtesy staff of the Israel Zion Hospital; adjunct in the department of gynecology at the Beth Moses Hospital, where he died August 24, aged 36, of malignant hypertension.

Thomas Longley Eland ⊕ Letts, Iowa; State University of Iowa College of Medicine, Iowa City, 1907; died in Iowa City October 27, aged 69, of arteriosclerotic heart disease.

Julius Essrig ⊕ Mount Vernon, N. Y.; University and Bellevue Hospital Medical College, New York, 1913; past president of the Mount Vernon Medical Society; fellow of the American College of Surgeons; member of the draft board during World Wars I and II; on the staff of the Mount Vernon Hospital; died October 9, aged 55, of hypertensive heart disease.

Eudora Winifred Faxon, Newton, Mass.; Tufts College Medical School, Boston, 1904; served as superintendent of the Woodlawn Sanitarium; died October 13, aged 68.

Dorsey Wayland Fellers, Bloomville, Ohio; Ohio Medical University, Columbus, 1902; served in France during World War I; formerly county health commissioner; on the staff of the Mercy Hospital in Tiffin; bank president; died October 28, aged 71, of cerebral hemorrhage.

Frederick Harrison Ferguson, Elroy, Wis.; Jenner Medical College, Chicago, 1906; served during World War I; died in Bay Pines, Fla., September 18, aged 74.

Henry Sampson Goodman, Cary, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1897; member of the American Medical Association; died October 24, aged 69, of coronary heart disease.

Yancey E. Gordon, Bucatunna, Miss.; Kentucky School of Medicine, Louisville, 1890; member of the American Medical Association; also a druggist; died October 16, aged 83, of pneumonia.

Henry Raymond Gross, Chicago; State University of Iowa College of Homeopathic Medicine, Iowa City, 1910; died near Milwaukee September 30, aged 61.

Bertram Johnson, Eureka, Kan.; Jenner Medical College, Chicago, 1908; Hering Medical College, Chicago, 1909; member of the American Medical Association; died September 12, aged 68.

William Craig Judd, West Los Angeles, Calif.; Willamette University Medical Department, Salem, Ore., 1906; died in the Veterans Administration Facility October 23, aged 62, of heart disease and diabetes mellitus.

Orville Kenneth Kaylor ⊕ St. Louis; Barnes Medical College, St. Louis, 1903; died October 24, aged 72, of arteriosclerosis.

Logan Guernsey Kimzey ⊕ Pullman, Wash.; Washington University School of Medicine, St. Louis, 1910; past president of the Whitman County Medical Society; died September 23, aged 67, of cerebral hemorrhage.

Carl Ross Knoble ⊕ Sandusky, Ohio; Starling Medical College, Columbus, 1905; past president of the Erie County Medical Society; formerly county coroner; for many years member and president of the board of education; medical examiner for the Metropolitan Life Insurance Company for many years; on the staffs of the Providence and Good Samaritan hospitals; past president of the Palm Brook Country Club; vice president of the Peoples Loan and Saving Company; died October 24, aged 65, of coronary thrombosis.

John Elias Kumpf ⊕ New York; Baltimore University School of Medicine, 1900; died October 9, aged 72.

Charles W. LaRue, Parrottsville, Tenn.; University of Virginia Department of Medicine, Charlottesville, 1893; died in the Takoma Hospital and Sanitarium in Greeneville, October 30, aged 75, of nephritis and pernicious anemia.

Roy Hamilton Long, Monroe, N. C.; Jefferson Medical College of Philadelphia, 1916; specialist certified by the American Board of Psychiatry and Neurology, Inc.; member of the American Psychiatric Association; served in France during World War I; assistant superintendent from 1938 to 1942 and for many years a member of the staff of the State Hospital in Morganton; died October 18, aged 54, of coronary thrombosis.

Melville LeRoy Loomis, Long Beach, Calif.; University of Southern California College of Medicine, Los Angeles, 1900; served on the staff of the Hospital of the Good Samaritan in Los Angeles; surgeon and medical director of the Douglas Aircraft Corporation; died in Santa Barbara October 14, aged 69, of coronary thrombosis.

William Tripner Dowler MacDonnell, Melrose Park, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1904; served on the staff of St. Luke's Hospital in Philadelphia; died in the Hahnemann Hospital, Philadelphia, October 28, aged 66, of coronary occlusion.

Lorne Mahaffey MacDougall ⊕ Brooklyn; M.B. in 1913 and M.D. in 1915, Queen's University Faculty of Medicine, Kingston, Ont., Canada; specialist certified by American Board of Otolaryngology; associate surgeon at the Brooklyn Eye and Ear Hospital; died October 3, aged 65.

Guy Elliott Marcy ⊕ Yakima, Wash.; State University of Iowa College of Medicine, Iowa City, 1908; served in France during World War I as a captain with Base Hospital number 50; on the staff of St. Elizabeth's Hospital; surgeon for the Northern Pacific Railway for twenty-five years; died October 24, aged 59, of cerebral hemorrhage.

Frank Eugene Mayberry ⊕ Rockland, Mass.; Dartmouth Medical School, Hanover, N. H., 1885; died October 1, aged 85, of diabetes mellitus and heart disease.

Malcolm McKellar ⊕ Tulsa, Okla.; Bennett Medical College, Chicago, 1913; member of the American Urological Association; specialist certified by the American Board of Urology, Inc.; medical officer in the medical corps of the U. S. Army during World War I; formerly chief of staff at St. John's Hospital; died October 8, aged 59.

Patrick James McLaughlin, Nashua, N. H.; Baltimore Medical College, 1906; member of the American Medical Association; on the staffs of the St. Joseph's Hospital and the Nashua Memorial Hospital, where he died September 8, aged 67, of acute dilatation of the heart and arteriosclerosis.

Walter Miles ⊕ Viola, Ill.; Rush Medical College, Chicago, 1898; died October 29, aged 77, of cerebral thrombosis.

Earl Joseph Morrow, Kansas City, Mo.; Medico-Chirurgical College of Kansas City, 1903; died October 7, aged 66.

Stephen Arthur Oliva, Marcus Hook, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1932; member of the American Medical Association; began active duty as a first lieutenant in the medical corps, Army of the United States, on Nov. 1, 1942; service terminated Sept. 24, 1943; drowned September 3, aged 39, when he fell from his yacht in Northeast River, Md.

George Byron Parisen, Toledo, Ohio; Western Reserve University Medical Department, Cleveland, 1908; served in the Spanish-American War and World War I; for many years surgeon at the Willys-Overland Motors Company; died October 16, aged 70, of arteriosclerosis and chronic nephritis.

John Porter Pennell ⊕ Kokomo, Ind.; Indiana University School of Medicine, Indianapolis, 1935; began active duty as a captain in the medical corps, Army of the United States, on Jan. 5, 1941; relieved of active duty during October 1944; died in a hospital at Columbus, Ohio, October 19, aged 34.

William D. Pennington, Chicago; Hospital College of Medicine, Louisville, Ky., 1894; on the staffs of the Illinois Masonic and Columbus hospitals; died in the American Hospital October 23, aged 88, of cerebral hemorrhage.

William Winston Pettus, Changsha, Hunan, China; Yale University Medical School, New Haven, Conn., 1937; diplomate of the National Board of Medical Examiners; interned at the Presbyterian Hospital in New York, where he served a residency; professor of surgery at the Hunan Yale Medical College; on the staff as teacher at Hsiang-Ya College of Medicine; had been affiliated with the Hunan-Yale Hospital; killed in an airplane accident at Hwangping, Kweichow, China, November 18, aged 33.

William Eugene Ranz ⊕ McAllen, Texas; Miami Medical College, Cincinnati, 1899; born in Cincinnati on March 20, 1873; member of the Ohio State Medical Association; past president of the Mahoning County (Ohio) Medical Society; fellow of the American College of Surgeons; for several years a member of the board of education in Youngstown, Ohio, where he was on the staff of the old Mahoning Valley Hospital and St. Elizabeth's Hospital; a captain during World War I; died October 20, aged 72, of coronary occlusion.

Robert Ellsworth Riley ⊕ Celina, Ohio; Rush Medical College, Chicago, 1893; also a graduate in pharmacy; on the staffs of the Gibbons Hospital and the Otis Hospital, where he died October 25, aged 82, of cerebral hemorrhage.

Arthur Maurice Rogers, Los Angeles; State University of Iowa College of Medicine, Iowa City, 1895; for twenty years assistant city health officer in charge of the venereal section clinic; died October 21, aged 76, of cirrhosis of the liver.

James Melburn Ruckman ⊕ La Rue, Ohio; Starling Medical College, Columbus, 1900; member of the La Rue and Marion County board of education; on the staff of the Marion City Hospital, Marion; died October 25, aged 73, of heart disease.

Levi Albertus Ruhl ⊕ Covington, Ohio; Jefferson Medical College of Philadelphia, 1905; died October 19, aged 68, of cerebral hemorrhage.

John G. Seiter, Marion, Ohio; Homeopathic Hospital College, Cleveland, 1881; served as mayor of Marion; died October 23, aged 93, of senility.

John Gill Shimmon ⊕ Cleveland; University of Wooster Medical Department, Cleveland, 1912; for many years member and frequently president of the Willoughby village school board and Union High school committee; served as president of the Northeastern Ohio Boy Scout Council; presented the Silver Beaver award in recognition of his valued services to boy scouting; member of the board of trustees of Andrews School for Girls in Willoughby; died in the Lakeside Hospital October 23, aged 61, of perforated duodenal ulcer.

Clyde Earl Shinkle ⊕ Cincinnati; Ohio-Miami Medical College of the University of Cincinnati, 1910; assistant professor of psychiatry at his alma mater, now known as the University of Cincinnati College of Medicine; member of the American Psychiatric Association; at one time assistant superintendent of the Longview State Hospital; on the staffs of the Speer's Memorial Hospital, Dayton, Ky., General, Deaconess and Good Samaritan hospitals; died October 5, aged 60, of bronchiogenic carcinoma.

Robert Simms, Akron, Ohio; Ohio Medical University, Columbus, 1903; died in St. Thomas Hospital October 29, aged 74, of coronary thrombosis and arteriosclerosis.

Capt. James S. Knipe, M. C., A. U. S., 1918-1945

John Knox Smith, Charleroi, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1888; served as a member of the first school board, for many years president of the board of health and postmaster of Charleroi; died October 8, aged 87.

Oscar H. Stewart ⊕ Orleans, Ind.; Pulte Medical College, Cincinnati, 1885; honorary member of the Indiana State Medical Association; died October 19, aged 85, of cardiovascular renal disease.

Thomas Hezekiah Street ⊕ Alexander City, Ala.; Jefferson Medical College of Philadelphia, 1900; served as secretary of the Tallapoosa County Medical Society, a member of the city council, member of the state legislature, state senator, city health officer and medical examiner for the Veterans Bureau; a captain in the medical corps of the U. S. Army during World War I; died October 24, aged 69, of coronary occlusion.

Samuel Gaines Stubbins ⊕ Birmingham, Ala.; St. Louis College of Physicians and Surgeons, 1907; member of the Southeastern Surgical Association; fellow of the American College of Surgeons; on the staffs of the Hillman Hospital and South Highlands Infirmary; died November 3, aged 65, of coronary thrombosis.

Samuel Henry Sulouff ⊕ Jersey City, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; also a graduate in pharmacy; served as a captain during World War I; for many years held various offices on the board of health; died in the All Souls Hospital, Morristown, November 2, aged 70, of bronchogenic carcinoma.

John S. Suva ⊕ Cleveland; John A. Creighton Medical College, Omaha, 1911; member of the Cleveland Academy of Medicine; died in St. Luke's Hospital October 16, aged 64, of injuries received in an automobile accident.

Horace Frederic Tangeman, Cincinnati; Ohio-Miami Medical College of the University of Cincinnati, 1912; member of the American Medical Association and the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Otolaryngology; served overseas during World War I; on the staffs of the Christ and Good Samaritan hospitals; died in St. Luke's Hospital, Chicago, October 11, aged 57, of coronary occlusion.

Ernest Julius Thierman ⊕ Cedar Falls, Iowa; Jefferson Medical College of Philadelphia, 1904; died September 13, aged 70, of cerebral hemorrhage.

Joseph Archibald Vance, Seattle; Eclectic Medical Institute, Cincinnati, 1886; died in a local hospital September 7, aged 86.

Dell Warner Ward, Oelwein, Iowa; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1906; member of the American Medical Association; died September 29, aged 63, of coronary occlusion.

Isabel Monteith Weaver, Kankakee, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1907; on the staff of the Kankakee State Hospital, where she died November 14, aged 64, of heart disease.

John Raymond Wilkinson ⊕ Kankakee, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1911; past president of the Kankakee County Medical Society; on the staff of St. Mary's Hospital, where he died November 9, aged 68, of cerebral hemorrhage.

KILLED IN ACTION

James Stuart Knipe, Armstrong, Iowa; State University of Iowa College of Medicine, Iowa City, 1943; interned at the Santa Clara County Hospital in San Jose, Calif.; diplomate of the National Board of Medical Examiners; began active duty as a lieutenant in the medical corps, Army of the United States, on December 29, 1943; in March 1944 received his assignment as battalion surgeon with the 381st Regiment, 96th Division, then stationed at Camp White, Ore.; received amphibious warfare training at San Luis Obispo, San Diego, and Camp Beale, Calif.; embarked for overseas duty from Camp Stoneman at Pittsburg, Calif., in July 1944; promoted to captain in September 1944; after several months' intensive training in Hawaii, participated in the invasion of Leyte Island on Oct. 20, 1944 and in the invasion of Okinawa April 1, 1945; killed in action in Okinawa April 12, aged 26.

Foreign Letters

PARIS

(From Our Regular Correspondent)

Dec. 26, 1945.

Anticancer Center in France

There are in France sixteen anticancer centers, created by private concerns with a certain participation of the public authorities. Of these the Institute of Cancer, the Curie Foundation and the Parisian District Anti-Cancer Center are in Paris. At first these centers dealt only with diagnosis and hospitalization. The Institute of Cancer, under the direction of Professor Roussy, with the Curie Foundation under the direction of Professor Lacassagne, comprises the largest center in the country. It has a laboratory branch for research and a branch for hospitalization; the latter in 1944 dealt with 7,690 patients, with 2,902 new cases; 2,023 were hospitalized. Since 1941 all the centers have dealt with the early diagnosis of cancer. The largest diagnostic centers are in Paris and Nancy; as a rule, 1 person out of 33 examined was found to have cancer. In 1943, as an experiment, Chevalier, director of the National Institute of Hygiene, created a medicosocial department at the Institute of Cancer. Since January 1944 all centers have been endowed with such a department, which, with the help of the district nurses ("assistantes sociales") follows up cancer patients for a five year period.

Difficulty in the development of the centers was due to lack of a regular and secure budget. By order of the former minister for public health these centers have become establishments of public interest and are endowed with a budget by the state. They consist of surgery and radiotherapy wards. Each center must secure the services of a cancer specialist, an otorhinolaryngologist and a pathologist. Each center provides care for a special area; this geographic distribution covers the whole of France.

A unique nomenclature for the types of cancer has been established for all centers. Forms of two types are used in the centers: One form for new patients gives their clinical and therapeutic history, another form is for the supervision of the patients; examinations during the year, relapses, metastasis and other incidents. This last form is sent every year to the National Institute of Hygiene. The center keeps in permanent touch with patients through the district nurse, and the Institute of Hygiene possesses a scientific record. At the beginning of 1945, 7,500 files had already arrived at the institute. In order to obtain more complete documentation, an inquiry is being made on the biologic condition of tumor bearers. The inquiry will be completed when 10,000 files have been received.

Experiment in Social Medicine at the Paris Hospital Clinic

The reform of hospital legislation is, at present, being studied and an experiment is in progress at one of the large Paris hospitals, Beaujon, which had been at the disposal of the United States Army and after being modernized and reequipped was returned to the French administration on Nov. 15, 1945. This hospital is to become a diagnosis and treatment center. It will be open to all social classes. Under the statute of the hospital medical staff, doctors will be under a five year contract. They will be allowed to treat their private patients in the hospital wards, but they must devote a daily minimum of three hours to the service of the public; attendance on outside patients would be, as a principle, prohibited to hospital doctors to avoid the dispersion of their activities and allow these doctors to devote themselves wholly to scientific research and teaching. This hospital clinic will receive large subsidies from the future social security fund. There will be a secretarial department to maintain connection with doctors who send patients to the establishment; they will find in this new organization means of diagnosis and treatment not now available to them. Time will show the results of this experiment.

Hospital Problems

A new medical journal on hospital technics has just been issued under the direction of Henri Thoillier, author of "The French Hospital." It is the first periodical in France to be devoted exclusively to hospital problems. Among the contributors are Professor Justin Besançon, president of the French Red Cross, Professor Debré of the Academy of Medicine, Dr. Hazemann, regional director for public health and assistance, Mrs. Randoin, general secretary of the Society of Alimentary Hygiene, Dr. Rouques, technical adviser to the Ministry of Public Health, other doctors, engineers, architects, managers and administrators of hospitals. The aim of this journal is to foster the collaboration of all persons concerned with hospitals in an attempt to modernize French hospitals. In the first issue there are articles on hospital legislation, medicine, surgery and hospital architecture. It includes two articles by Mrs. Randoin on dietetics and daily equilibrated rations, with menus for institutions. In the same issue Dr. Bridgman sets forth the situation of hospitals in devastated Brittany; in the four departments of this region 4,526 beds were lost and 10,035 still exist. The department of Loire-Inférieure, which in the past was the twenty-ninth on the departmental list of French hospitals, now is the eighty-first; surgery centers are disorganized. The greatest damage occurred in Brest, Lorient, St. Nazaire and St. Malo.

SWEDEN

STOCKHOLM, Dec. 14, 1945.

First Postwar Nobel Celebration

This year's Nobel celebration was one of the most splendid and impressive ever held. The memorable event was held December 10 at the Stockholm Concert Hall. After the royal family entered with fanfares, the Nobel prize winners took their places on the platform, this year's winners in the front row and the winners of prizes in previous years behind them. Only five of this year's winners were able to be present: Gabriele Mistral, winner of the prize in literature, Professor Artturi I. Virtanen, winner of the chemistry prize, and the three winners in medicine, Dr. Ernst B. Chain, Sir Alexander Fleming and Sir Howard Florey. The prize winners of previous years, who had been unable to come to Stockholm before, were Johannes V. Jensen, winner of the 1944 prize in literature, Professor Herbert Gasser, who in 1944 received half of the medical award, Professor Leopold Ruzicks, who in 1939 won half of the chemistry award, and Professor Corneille Heymans, 1939 prize winner in medicine.

In addition three Swedes, former prize winners, were present on the platform—Professor Manne Siegbahn, 1944 winner in physics, Professor The Svedberg, 1926 chemistry winner, and Hans von Euler-Chelpin, 1929 winner in chemistry. The Hungarian professor George Hevesy, who received the chemistry award in 1943, also was present. Never before had so many Nobel prize winners been present in Stockholm at one time, and the Swedes outdid themselves both in the decorations of the concert hall and in the festivities that followed the awarding of the prizes by King Gustaf. The following day the king gave a dinner for the prize winners and numerous other guests, after which papers were read by Fleming and Florey in the auditorium of the Karolinska Hospital on the background, development and uses of penicillin.

Penicillin Again Rationed

The Swedish Medical Board has been obliged again to institute rationing of penicillin. During its unrationed period its use was tripled. In September 18,230 ampules were used, in October 24,592 and in November 20,716. At the beginning of December the entire stock consisted of only 21,528 ampules, and the demands of the Swedish hospitals were not entirely filled. To cover the need during January and February, at least 50,000 more ampules are needed. Since the American authorities have announced that the supply to Sweden will be reduced during the coming months, and no other source of supply exists for the Swedes, the situation does not look too promising.

Antipoliomyelitis Serum

Dr. Sven Gard of the state bacteriologic laboratory reports promising preliminary results in the development of an antipoliomyelitis serum. Dr. Gard is chief of the research team which has been carrying on this work at the School of Physics and Chemistry at Uppsala University through a grant from the King Gustaf Jubilee Fund. An additional grant has just been awarded to enable research to continue for another three years. After innumerable general studies of the poliomyelitis virus, research is now concentrated on the development of prophylactic methods of immunity. It is in this field that promising preliminary results have been achieved.

ITALY

(From Our Regular Correspondent)

Naples, Dec. 11, 1945.

Control of Bubonic Plague

Eleven cases of bubonic plague were reported in August 1945 in the area of the port of Taranto, where ships from oriental countries were anchored. The patients were immediately isolated. Five patients died. New cases of human contagion did not occur. It is believed that the plague was due to the presence of infected rats. The city was quarantined, and schools and places of public meetings were closed. American sanitarians took an active part in cleaning up the port, which included a campaign against rats. Huge pasteboard rats with antiplague inscriptions were exhibited in public squares in Genoa, Naples, Bari, Palermo and other seashore towns. The inscriptions read "Rats are carriers of plague. Kill them, poison them!" Plague is now entirely under control. The sanitary condition of Naples is normal. The city is not in quarantine and has returned to civil and military activities. One may conjecture that if this epidemic had appeared in 1943 (instead of in 1945, as it did) it would have spread to all European countries. The organic resistance of 450,000,000 European people was very low in 1943. Many families passed several hours of the day and night in subterranean shelters in poor hygienic condition after their homes had been demolished by bombs. The scanty amount of proteins in their food caused an imbalance of albumins and globulins in the blood as well as disorders of the water metabolism, with a consequent rapid loss of weight, urinary disorders and a collective diminution of immunity to infections. If the epidemic had occurred in 1943 it would have been more acute than was influenza after the war of 1914-1918. The epidemic of influenza in 1918 caused six million deaths in Europe. In 1943 sulfanilamide was not available in some European countries. Germany had a large store of drugs early in the war yet was in need of drugs late in its course. A congress of German and Italian immunologists was held in 1942 in celebration of Behring's centennial. The Germans stated that typhus was frequent in Russian soldiers and that German soldiers at the Russian front were using an insecticide substance of the type of DDT which, when dissolved in water and applied to the clothes, killed lice. An article with details of this insecticide substance appeared on pages 232-233 of the *Allgemeine Zeitung* of May 16, 1943. This powder was not provided for the Italian soldiers. During hostilities the Italians used sulfonamide preparations of the types of thiazole and pyridine, by which massive pandemics of pneumococcic diseases were prevented. However, in 1940 the Società Medica Lombarda reported 30 cases of atypical bronchopneumonia caused by pneumococci which were resistant to sulfonamide. The rate of mortality was more than 50 per cent.

American Physicians in Italy

The pattern followed by epidemic foci in Europe was surprising. The epidemics in Italy, like those in France, consisted of salmonellosis due to the paratyphoid bacillus C, smallpox, infectious jaundice and some other infections. Salmonellosis was caused by ingestion of bad meat which was sold through the black market. Smallpox was mild and of the "alastrim" type (which is pandemic in Africa and is very acute in Negroes). In Italy there were many cases, but the mortality rate was low. The appearance of typhus in Italy was exaggerated in some American magazines. The infection in Italy was not caused by Rickettsia prowazeki, as was the infection reported at the Russian and Polish fronts. It is believed that it was caused by Borrelia recurrentis.

Captain Woodward of the United States, a member of the Interallied Committee Against Typhus, now in Naples, recently read a paper on the subject. There was a large audience of American and Italian physicians, among them Colonel Spalding of Detroit, Dr. Anton of Los Angeles and Dr. Schumacher of Illinois. Dr. Woodward spoke on the work of the American Sanitary Committee in Italy. The work carried on in Italy by American authorities in sanitation has resulted in immediate control of epidemics in the country. There were several hundred cases of typhus reported in Naples during January and February 1944. The epidemic was controlled in the course of a few weeks by the work of the American committee, which included administration of the Cox vaccine and disinfection with DDT. The population of Naples in 1944 was more than three million.

Experimental Adrenal Insufficiency During Pregnancy

Dr. Bernardo A. Houssay, the president of the Sociedad Argentina de Biologia, recently read a paper before the society in which he reported that 50 per cent of rats which are adrenalectomized during pregnancy die before parturition. If the animals drink a 1 per cent sodium chloride solution only 14 per cent of the animals die before parturition. The death rate is minimal during the second and third pregnancies after adrenalectomy even if the animals do not receive salt water. At this time the accessory adrenal glands have hypertrophied. The offspring of adrenalectomized rats are small in the first parturition. They are of almost normal size in the second and third parturitions. The number of animals for each parturition is normal. The rats which undergo parturition within ten or fifteen days after adrenalectomy have insufficient milk or none at all. The offspring of these rats die within a few days or grow in a poor nutritional state. The offspring of rats which had adrenalectomy between twenty-five and fifty days before parturition are normal. In relation to control animals, the weight of the adrenals in the offspring of recently adrenalectomized rats is diminished. The injection of adrenotrophine in pregnant rats causes hypertrophy of the adrenals of the pregnant animals but not of the offspring rats. Parturition is difficult for rats treated with the adrenotrophine and the fetuses die. The injection of desoxicorticosterone in pregnant rats prolongs pregnancy, the fetuses are abnormally grown, and parturition is difficult. The injection has no effect on the adrenals of the offspring.

Effect of Alloxan on Langerhans Islands of Rats

Dr. Arturo di Pietro recently reported results of experiments to the Sociedad Argentina de Biología. Eight rats had intraperitoneal inoculation of alloxan in different doses. The animals were killed at an interval of hours different for each animal for examination of the pancreas and the Langerhans islands. It appears in the literature that, when alloxan is intravenously given, microscopic changes of the pancreas and the Langerhans islands are observable within five minutes to one hour after the injection. The main changes consist of coagulation necrosis of the beta cells of the islands, whereas the alpha cells of the acinous tissue remain well preserved. The same changes are observed twenty-four hours after intraperitoneal injection. Progressive proliferation in the intercalary ducts and the cells of the central portions of the acini starts within seventy-two hours. Atrophy of the islands and degeneration of the beta cells follow. Hyperplasia of the ducts of the islands starts after abatement of the processes of cellular destruction and proliferation, with consequent nodular formation in the ducts and stimulation of the formation of regenerated alpha and beta cells. The former persist in regenerated islands, whereas the latter become necrotic.

Medical Graduates in Colombia

A plan of work to be followed by physicians during the first year after graduation was recently established in Colombia. The aim of this plan is to appoint physicians immediately after graduation to carry on medical work for one year in towns and zones far from the university centers (Bogota, Medellin and Cartagena). In these remote zones and towns the sanitary conditions are unsatisfactory and the number of physicians is small. The physicians will carry on medical work as well as biologic, demographic and epidemiologic studies. The latter will include physical geography, demography, birth rate, death rate, disease rate, general condition of sanitation in the given zone, nutrition, hygiene and economical status of the people, food and kind of salt consumed, social insurance and industrial diseases. The physicians will give with their final report after one year of work in a given zone their own suggestions for improvement of the people and of the living conditions. The physicians appointed will have previously an intensive course on elemental epidemiology and biostatistics. The foregoing plan is already established in Haiti, Mexico and Brazil with satisfactory results.

Experimental Diabetes in Relation to Sex

Dr. Virgilio G. Foglia of Buenos Aires, in a paper read before the Sociedad Argentina de Biologia, described the course of diabetes in subtotal depancreatized rats with loss of 90 or 95 per cent of the whole pancreas. Diabetic hyperglycemia appears in 88 per cent of male rats and in 40 per cent of female animals. The death rate during the first year after subtotal pancreatectomy is higher in the male than in the female. Hyperglycemia in male rats appears early after pancreatectomy and is of long duration. The results of the experiments seem to indicate an antidiabetic role of the ovary.

Brief Items

The Associación Argentina de Radiólogos was recently organized. Drs. Jose Guardado and Jose P. Uslenghi are the president and secretary, respectively, of the association.

A permanent committee of the pharmacopeia was recently established. The functions of the committee include the study of the Argentine pharmacopeia, biology and pharmacology. The committee will publish a national formulary.

Dr. Bernardo A. Houssay, the head of the Institute of Physiology of the Faculty of Medicine of the University of Buenos Aires, was awarded the 1945 Charles Mickle prize of the University of Toronto.

Dr. Jose Arce of the Faculty of Medicine of the University of Buenos Aires was recently appointed ambassador of Argentina to China.

BRAZIL

(From Our Regular Correspondent)

São Paulo, Dec. 6, 1945.

The Faculty of Hygiene and Public Health of São Paulo

On November 30 the Faculdade de Higiene e Saude Publica of the University of São Paulo was installed under the presidency of Prof. Paul Leitão da Cunha, minister of education and public health. The elevation of the old and well known Instituto de Higiene de São Paulo to the status of a university is one of the most important accomplishments of the government of the state of São Paulo under the supervision of the rector of the University of São Paulo, Professor Jorge Americano.

Among the different courses given in the Escola de Higiene e Saude Pública are public health courses for doctors and teachers, courses for technicians in public health laboratories and courses in dietetics. In July of this year Dr. Fernando Costa signed a decree forming the Institute of Hygiene and the faculty. The following professors constitute his first faculty: Geraldo H. de Paula Souza, Pedro Egidio de Oliveira Carvalho, Lucas de Assunção, Alexandre Wancolle, Francisco Borges Vieira, Francisco Antônio Cardoso, Benjamin Alves Ribeiro, Paulo Cesar de Azevedo Antunes, Rafael de Paula Souza, José Maria Gomes, Alvaro Guimarães Filho, Pedro de Alcântara Marcondes Machado, João Alves Meira, Vicente de Sampaio Lara, João Lane and Rubens Azzi Leal.

Brief Items

The São Paulo Society of the History of Medicine held a special meeting to honor the late Professor João Alves de Lima, whose distinguished services as a surgeon were emphasized by Dr. Sabastião Hermeto Jr. At the same meeting Dr. Flaminio Favero, professor of forensic medicine at the University of São Paulo, read a paper on "The Prohibition of the Use of the Blood among the People of Israel."

Dr. Euryclides J. Zerbini, associate professor of surgery at the University of São Paulo and surgeon of the Santa Casa Hospital, recently returned from the United States, where he spent some time as a guest of Harvard University.

Dr. Angel Roffo, professor at the University of Buenos Aires and director of the Experimental Cancer Institute of that city, spent a few days in São Paulo, where he gave a lecture on "Civilization and Cancer" at the medical center of the university. Dr. Roffo was made a doctor honoris causa by the São Paulo University.

Marriages

Dean Stephen Fleming, Minneapolis, to Miss Elizabeth M. L. Elliott of Thirlestane, Lauder, Scotland, recently.

John Dallas Hallahan, Lansdowne, Pa., to Miss Marion Elizabeth Laskey of Mount Airy, October 30.

A. C. Whittington, Bossier, La., to Miss Jimmie Evans of Farmerville, Texas, October 19.

Stephen Mayka to Miss Mary Jane LaIuppa, both of Rochester, N. Y., December 29.

Daniel Louis Fink to Miss Carroll Louise Shapiro, both of Minneapolis, November 18.

Maurice Nolan Bingham to Miss Virginia Ruth Watson, both of Seattle, October 19.

Robert G. Cook, Toledo, Ohio, to Miss Sarah Louise Sexton of Chillicothe, December 1.

Jack Greenfield, Cleveland, to Miss Janice Elrod of Rutherford, Tenn., January 2.

Harold Rifkin, Brooklyn, to Miss Beatrice Weiss of New York, November 25.

Horace R. Lyons to Mrs. Jeannette Gartz, both of Chicago, January 4.

Correspondence

PHYSICIANS NEEDED FOR MEDICAL MISSIONS

To the Editor:—With the return of large numbers of doctors and nurses from the armed forces—Army, Navy and Air Forces—there must be numbers of men and women ready to launch out in new fields of challenging, often arduous, service.

Lying on my desk today are many calls for doctors and nurses from overseas hospitals in Latin America and Africa, in Asia and the islands of the Pacific. Every sort of person is wanted—physicians, surgeons, medical teachers, research workers, health workers, nurses, expert dentists. So many of our fighting doctors and nurses have seen what Christian missions, both Catholic and Protestant, have meant to remote parts of the world that they must feel an urge to take part in the new health outreach. The numberless times our soldiers and sailors were rescued, whether in the islands of the Pacific or China or Africa, from almost certain death, make one realize what the influence of the Christian world mission has been.

The Christian Medical Council for Overseas Work is organized to answer questions that doctors and nurses may wish to ask as to place and conditions of service, as to the type of work involved and as to possibilities for further study and adequate preparation for careers as medical missionaries.

This letter goes out through you and The Journal to any whose attention may be arrested by our call. This office exists to bring men and women who are eager to serve overseas into touch with the medical and nursing opportunities that are waiting. We shall be glad to write, or to interview, any who will respond.

Douglas N. Forman, M.D.
Edward H. Hume, M.D.
Christian Medical Council for Overseas Work,
156 Fifth Ave., New York 10.

REVIEW OF BRADFORD AND SPURLING "INTERVERTEBRAL DISC"

To the Editor:—I have just read in the Dec. 15, 1945 issue of The Journal the review of the book by Drs. F. Keith Bradford and R. Glenn Spurling on the Intervertebral Disc, with Special Reference to Rupture of the Annulus Fibrosus with Herniation of the Nucleus Pulposus. In my opinion this review in its entirety is an unjustified and unscientific attack.

Although the review is not signed, the identity of the reviewer is perfectly evident to any one familiar with the history and literature of intervertebral disk surgery. Those readers not familiar with the history and literature of the intervertebral disk will unfortunately be led to accept it at its face value. The conservative approach of this book to diagnosis and treatment coincides with the opinions of almost all the neurosurgeons and orthopedic surgeons who have had wide experience with this condition and is in sharp contrast to the dogmatic, extravagant and unproved claims made by the reviewer as, for example, that "recent advances have completely transformed the field, both in diagnosis and treatment, to one of accuracy and certainty," as well as his unwarranted opinions regarding "concealed disks" and his dogmatic statements regarding fusion.

R. Arnold Griswold, M.D., Louisville, Ky.
Professor and Head of Department of Surgery,
University of Louisville School of Medicine.

(Comment.—Books received for review are submitted by the editor to physicians who have done work in the field and who are believed to be competent to express an opinion. Every possible effort is made to avoid the selection of reviewers who might have personal animus. Efforts are also made to avoid the selection of reviewers who would be personally biased in favor of an author. In other words, The Journal seeks critical reviews, not eulogies or malicious attacks. Reviews are published unsigned because it has been found impossible to obtain objective critical reviews with the signature of the reviewer.—Ed.)

TREATMENT OF TETANUS

To the Editor:—These are some personal observations on the treatment of active tetanus. After the fall of Okinawa and the surrender of many Japanese there were many wounded with active tetanus. They all had complete trismus, many with opistotonos, a few in coma.

Our treatment at first consisted in giving tetanus antitoxin intraspinally, intravenously and intramuscularly. The routine consisted of once daily intraspinal and intravenous administrations and a four hour intramuscular sequence. There occurred no change in the clinical state, and after ten days of this treatment without progress we tried the effect of penicillin.

The penicillin was given by once daily intraspinal and intravenous injection of 40,000 units and a four hourly intramuscular injection of 20,000 units. The improvement and eventual recovery following the institution of penicillin therapy was very impressive and warrants further investigation.

Harry L. Margulies, M.D., New York.

BENJAMIN RUSH—FIRST AMERICAN PSYCHIATRIST

To the Editor:—I have read with interest in the December 22 issue of The Journal the comment on page 1170 on Benjamin Rush, M.D. Benjamin Rush was a great man and he has many admirers. There was one claim to fame which was omitted from this little historical note, however; namely, that Rush was the author of the first systematic work on mental disorders published in this country (Medical Inquiries and Observations upon Diseases of the Mind) in 1812. The portrait of Benjamin Rush adorns the seal of the American Psychiatric Association, since in many ways he is properly looked on as the first American psychiatrist. His statue on the grounds of the old Naval Hospital in Washington bears on one side of the base the inscription "The first American alienist."

Winfred Overholser, M.D., Washington, D. C.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Cosmetology: Loss of Hair Resulting from Negligence of Beauty Operator.—This is an action to recover damages for personal injuries alleged to have resulted from the negligent acts of a beauty operator employed by the defendant. From a verdict in favor of the plaintiff and an order denying the defendant's motion for a directed verdict in his favor, the defendant appealed to the Supreme Judicial Court of Massachusetts.

The defendant was the proprietor of the Kilby Beauty Shop, of which the plaintiff had been a customer for over nine years, and on March 13, 1943 the plaintiff went to the shop by appointment to have her hair dressed by a "heat wave" with the electrical appliance that had been used on other occasions in performing such a service for her. When she arrived, a beauty operator in the employ of the defendant informed her that they had a new "no heat cold wave" which she recommended the plaintiff try. The plaintiff replied that she would prefer the "heat wave" but after some discussion consented to the use of this newer and more expensive method. It appeared from the evidence that the previous February the operator had attended a demonstration of the cold wave process at the place of business in Boston of the distributor of the preparation which was later used on the plaintiff's hair and that an order for the preparation was placed with the distributor. When the order was filled it was found to consist of four different solutions, one for fine hair, one for coarse hair, one for medium hair and one for overbleached hair. After obtaining the plaintiff's consent, the operator arranged her hair, which was abundant and of fine texture, on different spools and applied a liquid substance by patting it on the hair. During this process the plaintiff informed the operator that her head felt "numb and cold," but the operator replied that "that was the general result of the preparation." The operator later admitted, however, that this was the first time she had used the preparation. The process took about three hours and at its conclusion the operator held up her hands and said that "her hands were all split from the acid that was used and she had to go out and tape her fingers one at a time." About five days after the treatment had been given, the plaintiff ran her hand through her hair and "it came right out by the roots, in bunches." She returned to the shop and asked the operator whether or not the defendant had been informed of the circumstances. The operator replied that he had. Defendant then came into the shop and in his presence the operator stated "We used the wrong solution. . . . We had three solutions and we used the wrong one on your hair." The defendant replied "All right, we will give you some Breck shampoos" and "it will take care of it." The plaintiff then received a Breck shampoo, in the process of which her hair came out in "good sized bunches" so the "top of her head was perfectly bald." No charge was made for this shampoo. The plaintiff's hair kept falling out for five or six weeks and the bald spots on her scalp existed for about a year. In April following this treatment the plaintiff consulted a physician, who administered "lamp treatments" at different periods up to September, and new hairs were then just commencing to come in on the top of the plaintiff's head. Following the plaintiff's treatment, the operator called at the office of the distributor from whom the preparation had been received and as a result a representative called on her and told her not to use any more of the solution for fine texture hair. She used none thereafter.

The court said that the defendant was bound to exercise the ordinary skill and ability of persons engaged in the hair dressing business in Boston. On all the evidence, continued the court, the jury could properly have found that the preparation used by the operator had not been used by her before but that, when warned by the plaintiff that her head felt numb and cold, the operator nevertheless stated that that was the general result of the preparation; that on the conclusion of the work the operator's hands were split and bleeding as a result of the "acid" in the preparation; that in the presence of the defendant, who did not demur, the operator subsequently admitted that she had used the wrong solution. Furthermore, said the court, the jury could properly have found that the negligence of the defendant in the use of the wrong and harmful solution was the cause of the plaintiff's injuries. The jury findings being sustained by the evidence, the defendant's exceptions were accordingly overruled, and, in effect, the plaintiff's verdict affirmed.—*Cowhig v. Cafarelli, 63 N. E. (2d) 347 (Mass., 1945).*

Privileged Communications: What Action of the Patient Constitutes Waiver of Privilege.—The plaintiff sued to recover damages for injuries sustained when he fell through a trap door in the public sidewalk adjacent to the defendant's store. The defendant used this trap door for the purpose of receiving merchandise into its store basement. From a verdict and judgment in favor of the plaintiff, the defendant appealed to the Supreme Court of Utah.

The evidence showed that the opening in the sidewalk was in the shadow of an awning maintained by the defendant to shade its store windows, and that the plaintiff had impaired eyesight, but that he could have seen the trap door if he "had looked right down." Whether he used the requisite degree of care for his own safety was a jury question which was resolved in favor of the plaintiff. In asking for a reversal, the defendant contended, among other grounds, that the trial court erred in its ruling on the admissibility of the testimony of two physicians. It appeared from the evidence that a Dr. Dumke had attended the plaintiff when he was first taken to the hospital after the accident and that another physician, Dr. West, had taken various x-ray pictures of the plaintiff's back and skull. These pictures were taken at the request of Dr. Dumke to assist in his treatment of the plaintiff. At the trial the defendant attempted to prove by these two doctors that the x-ray pictures did not show any injury to the bone in the plaintiff's back but disclosed a pronounced arthritic condition which could not have developed as a result of this injury. On objection of the plaintiff, the proffered proof was rejected.

Section 104-49-3 (4), U. C. A. 1943, provides:

> A physician or surgeon cannot, without the consent of his patient, be examined, in a civil action, as to any information acquired in attending the patient which was necessary to enable him to prescribe or act for the patient.

The defendant did not contend that this section was inapplicable, but it did contend that the plaintiff, by testifying concerning the nature and extent of his injuries, waived the privilege provided for by the statute.

We have consistently held, said the court, that the privilege given by section 104-49-3 (4) is personal to the patient and may be waived. In this case, however, the plaintiff did not testify concerning anything which either Dr. Dumke or Dr. West told him nor did he give details concerning the mode of treatment. The plaintiff did not by his own testimony, therefore, waive the privilege. Furthermore, the use by the plaintiff of Dr. Kerr, another physician, as a witness on his behalf did not constitute a waiver. Dr. Kerr was subject to cross examination by the defendant. The x-ray pictures which he testified that he took and which he identified for the court were admitted in evidence. Dr. Dumke and Dr. West were both permitted to see these pictures and to testify in full as to what the pictures disclosed. The court therefore held that while a patient cannot testify concerning what was said and done by his physician in the treatment of the injuries which are subject to the litigation and then close the physician's mouth by claiming privilege, no such effort was made by the plaintiff in this case, and it therefore held that there was no error in refusing to admit the proffered testimony of Drs. Dumke and West. Judgment for the plaintiff was accordingly affirmed.—*Clawson v. Walgreen Drug Company, 162 P. (2d) 759 (Utah, 1945).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1936 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Quinacrine Hydrochloride in Malaria Prevention.—Boyd and Kitchen record experiments performed to ascertain the degree of protection against malaria afforded by various dosages of quinacrine hydrochloride (atabrine) when administered to patients inoculated with one or more species of malaria parasites at varying levels of inoculation intensity. Plasmodium vivax and Plasmodium falciparum react differently when inoculated into white patients routinely receiving quinacrine. The administration of 0.1 Gm. six days a week continued during the period of exposure has afforded complete protection against the falciparum infection but has not protected against a vivax infection. Even materially lower dosages appear in some instances to have protected against the falciparum infection and in the instances in which the infection became patent appear to have exerted a therapeutic effect before the onset of clinical activity. When the period of administration closely coincides with the time of exposure, doses of 0.1 Gm. a day for six days a week are inadequate to protect against a vivax infection. Even when the period over which these doses are given is extended to at least two weeks before and two weeks subsequent to the time of exposure, vivax infections later become clinically active, although exhibiting a more extended incubation period. Since vivax infections may, even without suppressive therapy, sometimes present protracted incubation periods approaching a year in duration, it is likely that a high proportion of persons who have received suppressive therapy will also finally experience clinically active vivax malaria after protracted incubation periods.

Transmissibility of Strains of Plasmodium Vivax.—From soldiers who had presumably acquired their infections in Pacific war areas, six strains of Plasmodium vivax were isolated by transfer of blood to patients who were candidates for malaria therapy. The clinical and parasitologic characteristics of the induced infections were not unlike those of infections with the McCoy strain of P. vivax, the strain of reference used throughout the study. Some of the patients with known or probable histories of former vivax infections demonstrated considerable immunity to the Pacific strain infections, 4 patients being refractory. When gametocytemia of these induced infections seemed to favor mosquito infection, Anopheles quadrimaculatus mosquitoes were fed. Subsequent to a minimum incubation period of seventeen days, these mosquitoes were examined for sporozoites. Salivary gland infections were demonstrated in mosquitoes fed on patients with infections with three of the six strains. Sporozoite transmission of these three strains was accomplished. At least some of the vivax strains from the Pacific war area are capable of being transmitted by A. quadrimaculatus.

Arsenotherapy of Early Syphilis.—A group of 210 patients with early primary syphilis were given three injections of oxophenarsine hydrochloride weekly for a total of twenty injections (six and two-thirds weeks). A single dose varied from 0.05 to 0.07 Gm., depending on weight. This course was followed by eight injections of bismuth salicylate 0.2 Gm. given twice weekly for four weeks. This course was immediately followed by ten arsenical treatments given twice weekly for five weeks. Only 63 of the 210 patients completed the treatment with satisfactory regularity and remained under observation for at least six months. Fifty-six of these (89 per cent) proved negative clinically and serologically, and 5 patients (8 per cent) proved seroresistant; there was clinical relapse in 2 (3 per cent) and serologic relapse in none. A total of 352 patients with syphilis were given three injections of oxophenarsine hydrochloride and one injection of bismuth subsalicylate weekly for eight weeks according to the Eagle plan. Only 109 patients completed the treatment in a satisfactory manner and have been followed for six to seventeen months. Thirty-three of the 109 were patients with early primary syphilis. It is desirable in appraising results to classify the types of early syphilis. Prognosis depends on the duration of the disease. Six of the 33 patients were classified as seronegative, and all proved negative clinically and serologically. Of 27 classified seropositive 23

(85.2 per cent) proved negative clinically and serologically. One seropositive patient (3.7 per cent) proved seroresistant, and 3 seropositive patients (11.1 per cent) were considered questionable. Failures have not occurred with any type of intensive therapy used for any patient with seronegative primary syphilis.

Undecylenic Acid in Dermatomycosis.—A new fungicidal preparation containing 20 per cent zinc undecylenate and 5 per cent undecylenic acid in a vanishing emulsion base (p_H 6.5) was tested clinically by Shapiro and Rothman in 150 patients with dermatomycosis presenting positive microscopic and/or cultural evidence of fungi. The pathogenic fungi grown on culture in this group were identified as Tricophyton gypseum, Tricophyton purpureum, Epidermophyton inguinale and Monilia. Complete clinical cure could be achieved with the undecylenate preparation within four weeks for the great majority of patients (86 per cent) with dermatomycosis pedis, regardless of the causative fungi. Relapses did not occur if treatment was continued. Comparative experiments have shown that the new preparation is only slightly superior to sulfur-salicylic acid preparations, but the undecylenate ointment is less irritating than any other preparation of similar fungicidal strength. Treatment with undecylenate ointment of patients with extended vesiculation, erosions, rhagades and edema of the feet can be employed without danger of irritation. In treatment of tinea cruris and tinea axillaris complete clinical cure was readily accomplished with the undecylenate preparation, regardless of the causative agent. In this group complete absence of any irritating action was noted as particularly important because of the pronounced irritability of large flexor surfaces. Results against tinea circinata so far are not entirely satisfactory. Infection of the glabrous skin with Microsporon audouini in adults and children responded well. In addition, 3 of 11 patients with tinea capitis caused by M. audouini were cured by the undecylenate ointment, so that x-ray epilation was not necessary. The results were not encouraging in onychomycosis.

Epidemic Pharyngitis Due to Hemolytic Streptococci.—Pewters and Bullock report an epidemic of acute pharyngitis and tonsillitis which occurred at an army air field. One hundred and fourteen cases were admitted to the station hospital during an eight day period. The onset was rapid, starting with sore throat, fever and malaise. The severe sore throat was accompanied by dysphagia and severe prostration in many cases. The temperature was usually between 101 and 103 F. and ranged between 100 and 105 F. Dusky red edema of the tonsils, uvula and pharynx and small yellow spots of exudate on the tonsils or pharyngeal wall were present. The submaxillary lymph nodes were usually enlarged and tender. The fever subsided by lysis in two or three days, and the sore throat gradually improved. Throat cultures were taken from 66 patients. About one half of these were taken after varying amounts of sulfadiazine had been administered. Fifty-five of the cultures were positive for group A hemolytic streptococci. All patients were treated with bed rest, forced fluids and sulfadiazine. Sulfadiazine 2.5 Gm. was given initially, followed by 1 Gm. every four hours. Sedatives were used as needed to control pain and dysphagia. Recovery was rapid. Three patients developed mild injection of the eardrum, which subsided without drainage or disturbance in hearing. All patients were examined weekly for six weeks. After three months rheumatic fever or nephritis had not developed in any patient.

*Human Food Poisoning Due to Growth of Clostridium Perfringens (C. Welchi) in Freshly Cooked Chicken: Preliminary Note. L. S. McClung.—p. 229.

Food Poisoning Due to Clostridium Perfringens.—The majority of the cases which have come to McClung's attention resulted from food eaten in a large public cafeteria. The symptoms included nausea, occasionally vomiting, intestinal cramps and severe diarrhea. In the majority of cases the symptoms began eight to twelve hours after the meal, with the diarrhea continuing for about twelve hours. Symptoms developed after eating chicken which was cooked one day and served on the following day. The chickens were cooked by steam under low pressure for three hours; they were then removed from the broth, which was saved for later use, and boned. Creamed chicken, croquettes prepared from the precooked chicken and similar dishes have been implicated and confirmed by bacteriologic evidence. The spoilage could be detected in many cases by the appearance of gas bubbles in liquid or semiliquid samples. In all samples of broth, but not necessarily with samples like croquettes, gram stains revealed heavy contamination with gram-positive rod forms which gave cultural and other reactions of

Clostridium perfringens. It seems reasonable to suppose that C. perfringens may be involved in the toxic spoilage of foods other than chicken and may have been overlooked. It is suggested that in the future those who are investigating outbreaks include the inoculation of suitable anaerobic mediums. In view of the ubiquitous distribution of the organism, its mere demonstration in a food may not necessarily mean that the food was contaminated sufficiently for this species to be the offending organism.

Obliteration of Bone Cavities Following Traumatic Osteomyelitis.—Knight and Wood point out that one of the most serious reconstruction problems in war casualties is the treatment of bone cavities associated with loss of skin and soft tissue following infected compound fractures. Especially difficult are large bone defects in the tibia and the femur in the vicinity of the knee. The authors have adopted a procedure which expedites healing and obliterates these cavities in the long bones of the extremities. Their method consists of three stages: (1) adequate sequestrectomy, (2) application of split skin grafts and (3) excision of the initial skin graft, application of bone chips and transfer of a full thickness skin graft. Of 23 cases treated in this manner the wounds in all but 2 have entirely healed. Bone sepsis has been eradicated in all cases and the defects have been eliminated. There has been no sequestration of any of the chips and no roentgenographic evidence of osteomyelitis following the insertion of the bone chips. In the 2 cases in which healing is not complete the bone defects have been eliminated and bony union is solid, but the soft tissue healing is not sound because of error in the skin graft technic, resulting in inadequate blood supply. Careful planning of the full thickness skin grafting will ensure sound healing.

Chemotherapy with Primary Closure of Septic Wounds.—After incision and drainage of an osteomyelitis area, two glass cannulas are inserted, and the wound is closed tightly around them. Rubber tubes are connected to the cannulas, one leading to a bottle of irrigating fluid at the head of the bed, the other to a waste bottle on the floor. At regular intervals irrigation fluid is allowed to flow through the wound until it comes out clear; the rubber tube from the outlet cannula is then clamped off, allowing the irrigation fluid to accumulate in the wound before the rubber tube from the supply bottle is clamped off. Later vitallium cannulas were substituted. Diluted solution of sodium hypochlorite has been used extensively and is often substituted temporarily for other chemotherapeutic agents. Silver pectinate solution has been used in a limited number of cases as a local chemotherapeutic agent but not as an irrigation fluid. Penicillin has been used for the last year. The system of two drainage and irrigation cannulas has been found to be a practical way of introducing the penicillin locally. Smith-Petersen and his associates, after eleven years with local chemotherapy administered through a closed system of cannulas, call attention to several favorable aspects: The almost complete primary closure reduces to a minimum the loss of serum from the granulating surfaces. The infrequency of dressings appeals to the patient and to the surgeon. The time for complete healing of the wound is materially shortened. The scar is linear and level. The postoperative clinical course in the majority of cases treated by this method has been smooth; the temperature chart levels off quickly; the patients are happy and look well. It is not a method with 100 per cent cures. There have been cases with local recurrence of sepsis, but these have been relatively few.

Rehabilitation of Patients Paralyzed Below Waist.—Munro asserts that a patient with a spinal cord or cauda equina injury who is intelligent and cooperative and has the use of the shoulder, arm and hand muscles can be made ambulatory, can have such control of the bladder and bowels as to sleep through the night without either getting up or wetting himself, can carry out ordinary activities throughout the day without soiling himself with feces or having to evacuate his bladder oftener than once every three hours, can lead a normal social life and can earn a living. This paper is the first of a series that describes certain therapeutic procedures that have made the attainment of these end results possible. The author has performed a bilateral dorsolumbar anterior rhizotomy on 10 patients. This bilateral intraspinal division of the anterior roots of the eleventh thoracic through the first sacral spinal nerve is recommended as a means of changing a spastic to a flaccid paraplegia in patients with an anatomic transection of the spinal cord at any point between the second thoracic and the second sacral segment preliminary to making the patients ambulant and to providing them with complete twenty-four hour control of micturition so that they may again become active members of their community and be self supporting. Because this operation is a permanently destructive one, the indications for performing it should never be considered lightly. For the present, at least, it should be strictly limited to patients in whom the spinal cord is anatomically transected and in whom all neural connections between the cut surfaces of the cord have been destroyed.

Cobra Venom in Angina Pectoris.—Freedberg and Riseman studied 12 patients with angina pectoris of coronary arteriosclerotic origin for various lengths of time. During the period of observation the frequency of the attacks in daily life became well known. The amount of work that could be performed under standardized conditions before pain developed had been determined on many occasions. The administration of cobra venom to patients resulted in an increase in the standardized exercise tolerance and in clinical improvement in 7 of the 12 patients studied. This occurred in 4 of 5 patients unresponsive to the usual medication employed in the treatment of angina pectoris. The optimum method of administration was 10 mouse units (1 cc.) three times the first day, followed by one injection daily for seven days; biweekly injections of 1 cc. were then necessary to maintain the effect. If escape from the drug occurred, repetition of the initial course of therapy sometimes produced beneficial effects. No untoward symptoms occurred with the dose recommended. Local pain invariably occurred, but in no case was it severe enough to warrant discontinuance of treatment. Cobra venom does not prevent the electrocardiographic changes associated with exertion in patients with angina pectoris. Its action is therefore not that of coronary vasodilatation.

Sodium Amytal Narcosis in Emotional Disorders.—Erb and Bond report the results of treatment with prolonged deep sodium amytal narcosis in a total of 311 flying personnel. The patients had early but true combat neuroses and were not men primarily physically fatigued. They all had one or more of the following symptoms: fear of flying or of combat flying, preoccupation with the hazards of combat, insomnia, vivid battle dreams, loss of appetite, irritability, depression, startle reactions, alcoholism, functional vomiting, tremor and, rarely, amnesia. The smallest dose of sodium amytal administered was 1.8 Gm. (27 grains) and the largest 24.6 Gm. (369 grains). The majority of the patients were subjected to a three day period of deep narcosis. Of the 311 men treated, 108 (34.7 per cent) returned to flying duty, 153 (49.2 per cent) returned to ground duty and 50 (16.1 per cent) were returned to the zone of the interior for rehabilitation. The treatment was considered successful in those who returned to combat flying in less than one month after treatment and who performed satisfactorily on more than four missions. This group is represented by 37 patients, or 11.9 per cent of all patients treated. More officers than enlisted men returned to flying duty, and more officers were successful after they had returned. The less severe the emotional reaction, the better the prognosis under this form of therapy. A greater percentage of men returned to flying and a greater percentage were successful when treated within four weeks of the onset of symptoms. In the immediate postnarcotic stage the patient frequently was overwhelmed with aggressive fantasies. The fantasies were often hallucinations concerning one form or another of mutilation and were extremely vivid and brightly colored. The massiveness of the release of aggressive thought is so impressive that its benefit or harm should not be overlooked when one is considering the effects of treatment. The patients who experienced this reaction in its most violent form were those who had rather serious emotional difficulty early in life, whether or not it had been apparent in adulthood.

Emotional Albuminuria in Flying Officers.—In a series of 935 officers returned from combat 49 had albuminuria of variable severity which could not be ascribed to organic disease. Fifteen minutes after withdrawal of blood for a Kahn test 160 of the officers had albumin in the urine. One hundred and eleven of these men had had normal urine before the emotional stimulus of venipuncture. Officers hospitalized for operational fatigue tended slightly to have more frequent and more severe albuminuria than those sent to duty. Plass suggests that such emotional albuminuria should be regarded as one of many signs and symptoms of a person's autonomic activity under conditions of decompensation. The phenomenon is probably less frequently observed in subjects as they become older.

Cervical Carcinoma.—Glücksmann and Spear applied a quantitative method by which the effects of radiation could be observed during treatment. The individual response to irradiation of 166 carcinomas of the cervix uteri treated since 1938 was assessed by means of a quantitative microscopic examination of serial biopsies. The subsequent clinical findings have confirmed the histologic assessment in the majority of tumors examined, the proportion of agreements increasing with time after treatment. The histologic assessment has therefore a useful prognostic value. A further series of 502 carcinomas of the cervix treated radiologically between 1930 and 1939 was classified on a preirradiation biopsy according to the degree of anaplasia and the results compared with the clinical follow-up, which covered a period of at least five years. In this series it was also found that the response of anaplastic tumors to irradiation tended to be less satisfactory than that of differentiating tumors.

*Cervicofacial Actinomycosis. A. B. MacGregor.—p. 639.

Cervicofacial Actinomycosis.—For years it was believed that workers associated with cattle or horses were more liable to actinomycosis infection than others, and the fact that similar looking organisms could be found on grasses and straw gave further credence to this view. Recent studies have shown that bovine and human strains differ and that the organisms present on vegetation are nonpathogenic for animals or man. Furthermore, anaerobic strains corresponding morphologically and culturally to the pathologic human Actinomyces israeli type can be found in normal mouths. It seems probable therefore that under certain circumstances, e. g. trauma, the organisms normally saprophytic in the mouth become parasitic and the disease manifests itself. This view is supported by the almost invariable history of trauma, e. g. extraction of a tooth or fracture of the mandible, which precedes the onset of the disease. In many cases the condition is not recognized. Patients may present a single abscess under the chin or on the neck or the classic form with multiple sinuses. In the 10 cases reviewed by MacGregor 6 started with a single abscess, though bacteriologic examinations showed the presence of true actinomycosis in these as well as in the remaining 4. Iodine and x-ray therapy have been the most widely used methods of treatment. In this series iodine was not used and x-rays were used on only 2 patients without especial success. Excision of the whole area in 1 localized case was performed without recurrence. One case with a submental abscess following fracture of the mandible was treated by drainage alone, without recurrence. Two patients were treated by injection of a suspension of sulfonamide into the infected area and along the sinuses without conspicuous success. Seven patients, including 1 of the sulfonamide failures, were treated with penicillin applied by means of thin rubber tubes inserted through incisions in the skin. In 4 of these patients the results were successful. The results of penicillin therapy were in agreement with the in vitro penicillin sensitivity, since the strain of organisms present in the failures were found to be much less sensitive than were those in the successfully treated cases.

Pleural Reaction in Primary Tuberculosis.—A primary tuberculous pleurisy develops when primary tuberculosis is at its height. This disorder is to be differentiated from postprimary exudative pleurisy, including the exudative pleurisy which develops within three to six months subsequent to the primary tuberculous infection and from the pleural exudate which is frequently associated with phthisis and miliary tuberculosis. Physical examination fails to demonstrate the pleural exudate, and even a careful roentgenologic examination in the sitting position will fail to disclose comparatively large exudates, which gravitate into the phrenicocostal sinus. Laurell's method, modified by Müller and Löfstedt, facilitates the roentgenologic demonstration of minimal amounts of exudate in the pleural cavity. Investigation on 120 healthy persons revealed that the most suitable projections may be obtained with the rays directed horizontally and by rotating the patient while recumbent on the affected side 20 to 30 degrees backward around his longitudinal axis and by elevating his hip so that the spine forms an angle of about 20 degrees with the horizontal plane. By this method fluid in the pleural cavity was demonstrated in 15 of the 120 examined persons (12.5 per cent). Thoracentesis demonstrated that 3 to 5 cc. of fluid may be disclosed by this roentgenographic technic. In 9 out of 10 patients with primary tuberculosis a pleural exudate was demonstrated on the affected side. The amounts of exudate aspirated by thoracentesis varied between 7 and 175 cc. The largest exudates were found in persons who were examined in the course of the first days after the onset of clinical symptoms. As a rule the exudate was absorbed in two to three weeks; in some cases small residual quantities persisted for a long period. These exudates have a high albumin content and contain a large number of polymorphonuclear cells. Guinea pig inoculation was positive in 2 cases. Demonstration of tubercle bacilli in the pleural exudate establishes the diagnosis of pulmonary tuberculosis even if tubercle bacilli cannot be recovered from the sputum or gastric contents. Determination of the cell content of the pleural exudate is an aid to early and definite differential diagnosis from acute pneumonia, which cannot be made unless the patient is studied for a prolonged period.

Book Notices

Electrotherapy and Light Therapy with the Essentials of Hydrotherapy and Mechanotherapy. By Richard Kovács, M.D., Professor of Physical Therapy, New York Polyclinic Medical School and Hospital, New York. Fifth edition. Cloth. Price, $8.50. Pp. 694, with 353 illustrations. Philadelphia: Lea & Febiger, 1945.

This is a presentation of the various phases of physical medicine with greatest emphasis on electrotherapy and light therapy. The author has revised many sections in order to include the newer concepts of electrophysics, ultraviolet irradiation and exercise and to bring the material in this rapidly changing field up to date. In addition, a special chapter on hypothermy has been added, as well as a glossary with general definitions of electrophysics, mechanotherapy and muscle and nerve action.

In an introductory chapter on physical therapy in the practice of medicine the basis and scope of physical medicine are described briefly. Following this, as was true of earlier editions, the book is divided into sections which deal with specific branches of physical medicine. Part I, on electrophysics, explains the fundamentals of this branch of physics and the generation, conversion and distribution of electricity. Much of this material is similar to that in the fourth edition, and the author again uses his comparison of the water system and electricity in order to explain the flow of electrons through a conductor. The electron theory of matter has been brought up to date and is explained in a fairly simple and comprehensible manner. Part II, on general electrotherapy and electrodiagnosis, includes material on currents of low frequency, high frequency, hyperthermy, electrosurgery, electrophysiology and electrodiagnosis. Because of the fact that static electricity has fallen generally into disuse, the author has condensed the material on this subject but states that "in competent hands the static apparatus is still a very useful and versatile piece of electrical equipment." Part III, on light therapy, has chapters on physics of radiant energy, ultraviolet radiation and heliotherapy and includes the physiologic effects of these modalities. Under special technics of ultraviolet irradiation has been added new material on ultraviolet irradiation of the blood. However, the author feels that too few clinicians have made reports on this procedure to make it preferable to other methods of treatment which require much less elaborate equipment and technics.

Part IV, on the essentials of hydrotherapy and mechanotherapy, is a concise description of hydrotherapeutic measures, massage and exercise. Here is a new chapter on hypothermy with descriptions of the mechanical apparatus devised for treatment as well as physical and physiologic effects and therapeutic considerations. Hypothermy also includes a brief but excellent discussion of cold injuries (immersion foot, chilblains and frostbite) with the present day methods of treatment. Part V, on applied physical therapy, gives indications and contraindications for physical therapy in most branches of medicine and surgery. Greatest emphasis is placed on the use of electrotherapy and light therapy in the majority of clinical entities, although the use of massage and exercise is mentioned rather briefly. Included are chapters written by collaborating authors who are specialists in their particular fields of medicine. Here too is material on physical therapy in office practice and institutional practice, which describes the planning of physical treatment, frequency of treatment, judging of results and selection of apparatus and personnel as well as a floor plan for a model physical medicine department in a hospital.

The author has included many pictures of equipment, diagrams and charts which are instructive and well arranged. Bibliographies at the end of a number of chapters give an opportunity to read further on material which may be too briefly handled in this book. The appendix contains tables of motor nerves and muscles as well as motor point charts which are necessary in electrodiagnosis. Because of the clear presentation of the material and the fine glossary, this book is useful either as a textbook for students of physical therapy or as a reference work for clinical practice.

Textbook of Bacteriology. By Edwin O. Jordan, Ph.D., and William Burrows, Ph.D., Associate Professor of Bacteriology, University of Chicago, Chicago, Illinois. Fourteenth edition. Cloth. Price, $7. Pp. 909, with 242 illustrations. Philadelphia & London: W. B. Saunders Company, 1945.

The passage of a textbook through fourteen editions over a period of almost forty years is sufficient evidence of its success. In the review of such a work it is necessary only to point out certain changes. The earlier editions were characterized by their emphasis on bacteriology as a biologic science. Although medical aspects of bacteriology were amply covered, the book was nevertheless a textbook of general bacteriology. Since Burrows has taken over the editorship he has continued to emphasize the fundamental importance of bacteriology as a science, but he has endeavored also to extend its usefulness along medical and diagnostic lines. This edition represents more than the usual type of revision in that several chapters have been completely rewritten. Rapid advances in the field of bacteriology have required this and the publishers are to be commended for their desire to make the revision a real one. In the present edition the chapters dealing with the yeasts, molds and Actinomyces have been completely rewritten, and the chapter dealing with the parasitic protozoa has been extended. Many new illustrations have been added, all of excellent quality. Particularly valuable are the chapters dealing with bacterial physiology, bacterial heredity and variation. In view of the confusion regarding classification of bacteria, the chapter dealing with that subject, including various classifications, enables one to understand better the reasons for the changing emphases. The chapters on the relationship of bacteria to disease and on resistance present the current points of view. One might question the retention of the old Ehrlich receptor theory with the pictures of receptors of the various orders, as this is now largely a matter of history, but perhaps in future editions this will be attended to. The book is beautifully printed and illustrated. There is no doubt that it will continue to serve its purpose even better in the future than it has in the past, owing in large measure to the scholarly way in which Burrows has planned the revision.

Human Biochemistry. By Israel S. Kleiner, Ph.D., Professor of Biochemistry and Physiology, New York Medical College, New York. Cloth. Price, $6. Pp. 573, with 75 illustrations. St. Louis: C. V. Mosby Company, 1945.

This is essentially a textbook of biochemistry for the medical student. It is not a suitable reference work for the practicing physician. The author has made a laudable attempt to relate the subject matter to clinical medicine in sufficient detail to lend interest and significance to the chemical facts, but briefly enough so that the student is not diverted too far or too long from the fundamental subject. There can be little doubt that the book will prove more interesting to medical students than were former textbooks which neglected the clinical aspects. However, this seems to have been accomplished at the expense of fulness and depth in the presentation of the biochemical matter. It may be that through the use of this book the student will learn less biochemistry but will remember and apply a proportionately greater amount in his clinical thinking. It would be of considerable pedagogic importance to know whether this does or does not turn out to be the case.

Clinical Parasitology. By Charles Franklin Craig, M.D., M.A., F.A.C.S., and Ernest Carroll Faust, M.A., Ph.D., Professor of Parasitology in the Department of Tropical Medicine, Tulane University of Louisiana, New Orleans. Fourth edition. Cloth. Price, $10. Pp. 871, with 309 illustrations. Philadelphia: Lea & Febiger, 1945.

The publication of a fourth edition within two years of the third edition attests the deserved popularity of this authoritative textbook of medical parasitology. Text material has been revised and brought up to date and thirty-one illustrations have been added. Information concerning DDT and other wartime advances in disease prevention is included. However, the recommendations on the use of atabrine in the section on the treatment of malaria do not take full account of recent military experience with the drug. Summary tables of the diagnosis and treatment of parasitic infections are provided for the student. The completeness with which the subject is covered and the extensive bibliography also make the volume valuable for reference purposes.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

PROGRESSIVE MUSCULAR DYSTROPHY

To the Editor:—A man aged about 26 is afflicted with progressive muscular dystrophy, probably of the Erb type. The patient has been examined by numerous clinics throughout the country, including the Mayo Clinic, but, in spite of aminoacetic acid and numerous other attempts at treatment his condition is slowly progressing. The patient is quite discouraged, and the family is willing to try anything that might help his condition. Would it be possible for you to forward a copy of this letter to some physician, foundation or clinic that has been doing experimental work in the treatment of this unfortunate disease? R. W. Sleeter, M.D., Medford, Ore.

Answer.—No effective specific therapy for progressive muscular dystrophy yet exists. Many types of treatment have been proposed, but each of these after extensive observations has been demonstrated to be without effect. An abnormality in creatine metabolism with an increase in urinary excretion of creatine and a decrease in creatinine excretion accompanies the disease. It has been demonstrated that changes in creatine excretion may be effected in the dystrophic patient by the administration of a number of substances. These include gelatin (Gibson, R. B., and Martin, F. T.: *J. Biol. Chem.* **49**:319 [Dec.] 1921), aminoacetic acid (Brand, E.; Harris, M. M.; Sandberg, M., and Ringer, A. I.: *Am. J. Physiol.* **90**:296 [Oct.] 1929), pancreatic extract (Meldolesi, G.: *Policlinico* [sez. prat.] **43**:1187 [June 29] 1936), vitamin E (McBryde, A., and Baker, L. D.: *J. Pediat.* **18**:727 [June] 1941) and testosterone (Hoagland, C. L.; Shank, R. E., and Gilder, H.: *Proc. Soc. Exper. Biol. & Med.* **55**:49 [Jan.] 1944). However, administration of these substances to large groups of patients for prolonged periods has failed to provide objective evidences of improvement. Recently in a preliminary communication Milhorat and Bartels described a decrease in creatinuria in progressive muscular dystrophy which occurs when a condensation product of alpha tocopherol and inositol is administered (*Science* **101**:93 [Jan. 26] 1945). Only a small group of patients was treated, and no statement was made concerning the effect of this compound on other manifestations of the disease. None of the substances so far used in therapy have been shown to increase the creatinine output of patients with progressive muscular dystrophy. According to evidence presented by Hoaglund, Gilder and Shank, the decrease in the urinary excretion rate of creatinine is more closely related to the amount and degree of involvement of muscle than is the creatinuria (*J. Exper. Med.* **81**:423 [May] 1945). Moreover, effective therapy should be accompanied by objective evidences of improvement in muscle function and by the disappearance of signs of degeneration and atrophy of the affected musculature.

Despite the fact that specific forms of therapy are lacking, certain considerations in the general care of the patient with progressive muscular dystrophy may postpone the development of incapacitating contractures and the onset of a state of complete invalidism. Patients should be encouraged to use affected musculature as long as even minimal function remains. Periods of prolonged bed rest have been observed to accelerate the process of muscular atrophy. For this reason it is of importance to protect these patients from infectious diseases and illnesses which may make bed rest necessary. Excessive muscular exertion may precipitate more rapid progress of the disease. Therefore, exercise and use of the affected muscles should not be carried to the point of fatigue. Lipodystrophy with deposition of large masses of subcutaneous fat often accompanies the disease. The provision of a diet meeting basal requirements but not permitting excessive weight gain may protect diseased muscle from work loads which are unnecessarily great.

STREPTOMYCIN IN TUBERCULOSIS

To the Editor:—What is the efficacy of streptomycin or any other medication in the treatment of primary childhood tuberculosis? My little daughter has contracted the infection (none in the family—it must have been through a nurse or maid) and I am afraid of hematogenous dissemination, as her condition is poor. M.D., New York.

Answer.—Streptomycin, an antibiotic isolated by Waksman and his co-workers (Waksman, S. A., and Woodruff, H. B.: *Proc. Soc. Exper. Biol. & Med.* **49**: 207 [Feb.] 1942), from a soil Actinomyces—Streptomyces grisei—has been found to be useful in controlling infections by many gram negative microorganisms. In tuberculosis the effect is limited but promising. Most of the reports to date have been made by Hinshaw and Feldman and others, at the Mayo Clinic (Feldman, W. H.; Hinshaw, H. Corwin, and Mann, Frank C.: *Am. Rev. Tuberc.* **52**:269 [Oct.] 1945. Feldman and Hinshaw, *ibid.*, p. 299). The effect on animal tuberculosis, reported by the authors and others (Youmans, Guy P., and McCarter, John C., *ibid.* **52**:432. [Nov.] 1945) has been more favorable than any other agent tried up to the present time. Many animals were made bacillus free following the treatment.

In human disease the results have been encouraging but not as good as in animals. There seems to be little doubt that the drug retards certain types of tuberculous infections. It is too early, however, to say how permanent are the effects on tubercle bacilli, but open kidney lesions, lymph node lesions, sinuses, lesions of mucous surfaces, late generalized miliary pulmonary lesions and miliary lesions associated with primary infections have been noted to change and partially disappear following streptomycin treatment. The course of the disease in some cases of tuberculous meningitis has been modified, but as yet recovery has not occurred. The changes, however, in ordinary lung tuberculosis have not been sufficient to warrant enthusiasm.

Of almost equal importance to the effect on the disease is the low toxicity of the drug. With few exceptions ill effects from daily doses of several million units, even when administered to infants, do not occur. In a few cases there has appeared to be a slight disturbance of the labyrinth, either directly or as an effect on the nerve. However, the loss of equilibrium seems to be transient and present in only a few cases.

The older the child, the less is the possibility of meningitis and the greater is the possibility of survival as a result of ordinary hygienic care. Streptomycin is probably harmless, although experience is not yet sufficient to say this with certainty. A course of streptomycin treatment might be considered as an experiment when the drug becomes available.

GEOGRAPHIC DISTRIBUTION OF DIABETES

To the Editor:—I have been told by practitioners in Maine that the morbidity rate of diabetes mellitus in that state is unusually high. Do the statistics bear this out? Has it been shown that geographic distribution plays a part in the etiology of the disease? M.D., New Jersey.

Answer.—Statistics are not available for the morbidity rate of diabetes in Maine. In 1944 sixteen states in the United States had a higher death rate from diabetes during the first nine months than did Maine. In this period Maine showed a death rate per hundred thousand of 28.3. The average for thirty-nine states and the District of Columbia was 27. The state with the highest death rate from diabetes was New York with 42.4, and then followed New Hampshire 38.9, Rhode Island 37.8, Massachusetts 37.3, Pennsylvania 35.3 and Vermont 35.7.

Geographic distribution does not play a part in the etiology of diabetes, but the field is open for intensive research. A survey of Arizona, where the mortality rate for diabetes per hundred thousand in 1937 was 10, as compared with that of Rhode Island, in which it was 42, demonstrated that when the age of the population, sex, number of Jews, obesity, medical supervision and deaths available for statistical purposes were considered the morbidity rate of the two states was approximately the same.

SKIN IRRITATION FROM CYANIDE IN CADMIUM PLATING

To the Editor:—In cadmium plating the solutions used are cadmium or sodium cyanide. Is there a nonpoisonous and relatively nonirritating substitute for the cyanide solution? It need not be as good as the cyanide solution if it could give fair results.

Aaron N. Gorelik, M.D., Bronx, N. Y.

Answer.—At the present time in cadmium plating, cyanide solutions are almost invariably employed. From the point of view of quality of results and economy, cyanide solutions are greatly preferred in the trade. However, it is common practice to use along with the cyanide solution sodium carbonate or caustic soda. While this is done for product reasons rather than for protection of the worker, some benefit derives because the presence of such alkalis hampers the liberation of hydrocyanic acid, and the quantity used does not increase the probability of skin irritation. The only known substitute for cyanide baths are sulfate baths, but the product obtained is frequently less perfect than with cyanide solution. In case highly lustrous coatings are desired, sulfate baths in some instances may be used to advantage. The chief objection to sulfate baths is the rough crystalline character of the plating with a disposition toward treeing, which is often undesirable. To a degree this may be overcome through the addition of colloidal agents such as gelatin. This matter is discussed in "Modern Electroplating" (American Chemical Society, Inc., Columbia University, New York, 1942). In all other forms of electroplating cyanide baths are far less indispensable. Although cyanide is widely used in copper and indium plating, suitable substitutes are available, particularly in the case of indium plating, in which sulfate baths are increasing in popularity. Through the use of adequate exhaust systems and skin protection, cyanide baths in cadmium plating may be made essentially noninjurious.

DOSE OF ACETYLSALICYLIC ACID FOR HEADACHE

To the Editor:—What is the pharmacologic basis that determines the dose of acetylsalicylic acid used in the treatment of simple headaches for which no apparent cause can readily be found? Is 5 grains as efficient as 10 or 15 grains for an anodyne effect? What is the optimum time interval between doses?

M.D., District of Columbia.

Answer.—The basis for dosage is largely empirical. Clinical custom is to administer about 0.6 Gm., repeated if necessary every three or four hours. Although one cannot directly transfer available experimental evidence to the clinical problem of headache, the presumption is that such findings as those of Wolff, Hardy and Goodell (*J. Clin. Investigation* 20:63 [Jan.] 1941) are relevant and indicative of general effects. Thus it was shown that if the pain produced by heat focused on the forehead could be relieved at all, 0.3 Gm. of acetylsalicylic acid would give a maximum degree of relief, but that 0.6 or 0.9 Gm. would prolong the effect somewhat. Also administration of 0.3 Gm. every two hours gave more sustained relief than 0.6 Gm., or more, every three hours. One might conclude therefore that *the customary clinical dose is too large and the administration* too infrequent. However, simple headache often responds to one dose, in which case the larger amount would presumably be more lasting and therefore more useful. In any case, treatment is unlikely to be long continued and so toxicity is not greatly to be feared. Until more direct evidence is available it is probably advisable to use a dose of 0.6 Gm., repeated every two to four hours as necessary, for the relief of simple headache.

INABILITY TO GAIN WEIGHT

To the Editor:—A woman aged 20, single, who has been under my care for five weeks, is definitely underweight and has a history of having been in a sanatorium for possible tuberculosis for nineteen months ending May 1944. She complains of poor appetite but doesn't feel tired, and aside from the anorexia and underweight the physical examination reveals practically nothing. I put this girl on a high calory diet. She kept a count of her calories and averaged 2,700 to 3,000 calories a day. The first week she gained 2 pounds (0.9 Kg.), for four weeks she remained at exactly 93 pounds (42 Kg.) and today was down to 90 pounds (41 Kg.). Although she does not have a goiter, I made a test of her basal metabolism this morning; the result was minus 1.5. Why doesn't this young woman gain weight in spite of the normal thyroid action and high caloric intake? She does not work except possibly for light housework. The last x-ray at the sanatorium showed the tuberculous lesions to be well healed. She does not have clinical symptoms of active tuberculosis at present. What other conditions must one consider in connection with this girl?

T. G. Harvey, M.D., Fort Fairfield, Maine.

Answer.—The law of the conservation of energy still holds. If the patient claims that she is eating 2,700 to 3,000 calories a day and maintains her weight at 90 pounds in spite of a normal level of metabolism, she either does not know what a calory is or imagines that she eats more than she actually does or else disposes of her food and claims that she eats it. It is assumed, of course, that the patient has been carefully studied and does not have diabetes mellitus.

The case is recalled of a student who had a basal metabolic rate of −25 per cent and weighed 75 pounds (34 Kg.). She insisted that she was taking 2 grains (0.13 Gm.) of thyroid and 1 quart (liter) of 20 per cent cream daily in addition to her meals. In spite of her statement, her basal metabolism remained at the low level and her weight did not increase. She was finally placed in the hospital for observation. The administration of desiccated thyroid was continued and she was placed on a diet about 3,500 calories. Her basal metabolism still remained at a level of approximately −25 per cent and her weight at a level of about 75 pounds. All the food that was served to her disappeared from her tray. The mystery was solved when the maid on the floor caught the patient one day throwing her food in the toilet seat which was in her room. From then on she began to gain weight.

BRUCELLOSIS OR TULAREMIA AND BLINDNESS

To the Editor:—A boy aged 9 years has been ill for five weeks. At the beginning he had a definite pallor, then a jaundiced appearance over the entire body followed by fever and an enlargement of all lymph nodes. He complained of pain in the joints and headache. There was no ulceration or breaking down of any of the glands. His face and eyes were swollen. Two weeks ago his hearing and vision began to fail, until he became partially deaf and almost totally blind. A blood test has been taken and the disease pronounced tularemia. At the present time he does not suffer pain and his appetite is good with only slight nausea and a burning in the stomach. His temperature varies from normal to 102 F., the pulse rate is 100 and the respiratory rate is around 20. His face and eyes are still swollen. His hearing has improved, but he is still blind. I cannot find reports of involvemeent of the eyes and the ears in any of the medical literature I have on the subject, and none of the physicians with whom I have talked have ever heard of this complication. Treatment has been supportive.

V. P. Jackson, M.D., Pinehurst, Ga.

Answer.—Insufficient information is given to make a diagnosis. Except for rare cases of oculoglandular infection, diminution or loss of vision has not been recorded for tularemia. The type of onset and the early clinical course described do not suggest tularemia. The agglutination test for tularemia should be repeated. At the same time request should be made for agglutination of Brucella and Leptospira. Additional helpful information toward a diagnosis would include a complete blood count and examination of the fundus for evidences of optic atrophy or of choking of the disk that might imply cavernous sinus thrombosis. Both of the latter have been observed in brucellosis, and serum from some patients with this infection will agglutinate Bacterium tularense.

ACETANILID AND SULFHEMOGLOBINEMIA

To the Editor:—A patient has sulfhemoglobinemia apparently as a result of long continued ingestion of B. C. headache powders. The diagnosis has been proved spectroscopically. What is the latest treatment of this condition? The patient also has latent syphilis with positive serologic reaction after nine months of weekly treatment elsewhere. Have syphilis and sulfhemoglobinemia in the same patient been reported previously, and would treatment of one condition affect the other in any way?

Maurice J. Small, M.D., Parsons, W. Va.

Answer.—Acetanilid, which has been reported in B. C. headache powder, has been reported to cause sulfhemoglobinemia (Morgan, T. N., and Anderson, A. Greig: *Brit. M. J.* 2:187 [Aug. 10] 1940). There is no special treatment for sulfhemoglobinemia. Recovery occurs slowly after discontinuation of the offending drug. Record of syphilis and sulfhemoglobinemia in the same patient has not been found. As antisyphilitic drugs have not been shown to produce sulfhemoglobinemia, their use is not contraindicated in this condition. The recent literature on this subject is concerned mainly with sulfonamide therapy as an etiologic factor.

DIAGNOSIS OF ACUTE CHOLECYSTITIS

To the Editor:—Is it possible to have an acutely infected gallbladder without bile in the urine, a negative van den Bergh reaction and an icterus index of 9?

J. M. Bodenheimer, M.D., Shreveport, La.

Answer.—The presence of bile in the urine, a positive direct van den Bergh reaction and an elevated icterus index all indicate the presence of obstruction in the biliary passages beyond the union of the cystic and hepatic ducts. Acute cholecystitis does not necessarily imply the presence of inflammatory obstruction in the required area, so acute cholecystitis may exist without the signs of biliary obstruction. When the signs of biliary obstruction appear, one assumes that the inflammatory process has spread into the bile passages. The icterus index of 9 is slightly above the usual normal range but is still below the level of clinical jaundice.

TEMPERATURE AND HUMIDITY IN OPERATING ROOM

To the Editor:—At what temperature should an operating room be kept for abdominal surgery and for general surgery other than abdominal, if there is any difference?

M.D., Vermont.

Answer.—A temperature between 78 and 80 F. has been found satisfactory at one of the leading hospitals. No attempt is made to control the humidity. When the operating rooms are air conditioned, the humidity is kept between 50 and 55 per cent and the temperature range is from 70 to 80 F. in direct relation to the humidity. This has been considered ideal for general surgery.

TOXIC MANIFESTATIONS OF THIOURACIL THERAPY

A COOPERATIVE STUDY COMPILED BY FRANCIS D. MOORE, M.D.
Massachusetts General Hospital, Boston

Cooperating Clinics: BARNES HOSPITAL AND WASHINGTON UNIVERSITY SCHOOL OF MEDICINE, St. Louis, Cyril M. MacBryde, M.D.; BETH ISRAEL HOSPITAL, Boston, Samuel L. Gargill, M.D., and Mark F. Lesses, M.D., BOSTON CITY HOSPITAL AND MASSACHUSETTS MEMORIAL HOSPITALS, Boston, Robert H. Williams, M.D., and Howard M. Clute, M.D.; JEFFERSON MEDICAL COLLEGE AND HOSPITAL, Philadelphia, Karl E. Paschkis, M.D., Abraham Cantarow, M. D., and A. E. Rakoff, M.D.; JOHNS HOPKINS HOSPITAL, Baltimore, Elliot V. Newman, M.D., and John E. Howard, M.D.; LAHEY CLINIC, Boston, Elmer C. Bartels, M.D.; MASSACHUSETTS GENERAL HOSPITAL, Boston, James H. Means, M.D., Rulon Rawson, M.D., and Oliver Cope, M.D.; MAYO CLINIC Rochester, Minn., Samuel F. Haines, M.D., and F. Raymond Keating Jr., M.D.; NEW YORK HOSPITAL, New York, David P. Barr, M.D., and Ephraim Shorr, M.D.; PRESBYTERIAN HOSPITAL, New York, Walter W. Palmer, M.D., Sidney C. Werner, M.D., and Henry Aranow, M.D.; UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, London, England, H. P. Himsworth, M.D., M. E. Morgan, M.D., and J. M. Stowers, M.D.; UNIVERSITY OF CALIFORNIA MEDICAL SCHOOL, San Francisco, Mayo Soley, M.D.

Increasing evidence of the usefulness of thiouracil in the treatment of thyrotoxicosis [1] has been accompanied by the appearance of many reports concerning the toxicity of this drug. Not infrequently these published reports refer to isolated cases or are unaccompanied by full numerical data from the series involved. It is possible, therefore, that they may give an erroneous impression of the frequency of toxic reactions. Before the usefulness and final place of this drug can be settled, we must be able to balance its toxic manifestations against its pharmacologic advantages, and for this reason an accurate estimate of the incidence of severe toxic manifestations in patients under treatment with the drug should be a useful adjunct to our knowledge.

Therefore it has seemed advisable to gather together data from a large group of patients treated with thiouracil so that the actual incidence of toxic manifestations might be studied in relation to the total number of patients treated. In this way accurate statistics on the expected incidence of toxic reactions should be obtained. To accomplish this end the present group of eleven clinics in this country and one in England have accumulated their joint experience with toxic reactions, and these data are herewith presented. It should be stressed that this material is presented in an attempt to arrive at an accurate figure for the incidence of toxic reactions; it is not in any sense an appraisal of the usefulness of thiouracil or an attempt to define the limits of its applicability. Nor is it, further, an attempt to settle the present controversy as to whether this drug should be used as a treatment of thyrotoxicosis per se or in the preoperative preparation of patients for thyroidectomy.

It is of interest that the preparation of patients for surgery can usually be accomplished with this drug in eight weeks or less, and therefore the additional question presents itself of the time relationships of various toxic reactions. An attempt at analysis with respect to these factors will also be presented.

A further consideration in the method of analysis used has been the fact that thiouracil appears to have one potentially fatal toxic manifestation, that concerned with an effect on leukocyte production. Unlike the sulfonamides, thiouracil appears to carry only this major hazard at the present time. It is true that severe hepatic damage has been reported and several instances occurred in the present series of patients, but thus far these lesions have not proved fatal and have been amenable to the usual forms of treatment. The present effort has been to obtain accurate data on the incidence of the hematologic reactions rather than a tabulation of the host of other less dangerous reactions which may occur also with thiouracil and which doubtless will continue to be reported in new forms as time goes on. For this reason the incidence of agranulocytosis and leukopenia are the chief concerns of this investigation. The statistics concerning drug fever, skin eruptions, psychotic manifestations, lymph node enlargement, salivary gland disorders, hepatic damage and other reactions have not been stressed, and the data on these reactions are not intended to be definitive.

These cases include many of the first in which treatment with thiouracil was administered, and, as experience grows, means of avoiding these reactions may become evident.

In table 1 is shown a list of the clinical groups cooperating in this study and the number of patients treated by each group.[2]

The accumulated experience of this group of clinics comes to a total of 1,091 patients, a number which is probably large enough so that the incidence of toxic manifestations during thiouracil therapy may be regarded as statistically significant. The length of time during which these patients were under treatment covers a broad range from patients treated two weeks (less than 1 per cent of the series) to a very few patients treated for periods up to two years or more. The great majority of the patients were treated between two and eight months. The dosages have been variable, but they have varied within a fairly narrow range and, as will be seen later, do not materially affect the analytic results. Most of the clinics have employed 0.5 to 0.8 Gm. a day for a period of three to seven weeks or until the basal metabolic rate fell to normal or nearly normal levels. The dosages have then been cut to 0.2 to 0.4 Gm. per day, and those clinics which have carried the patients on for many months without surgery have further cut the dosage to as low as 0.1 Gm. or less per day or every other day. The clinics which have employed the drug largely as a preparation for surgery have tended to maintain higher dose levels, but for a shorter period of time; one group reports an average duration of preoperative treatment of fifty-seven days in the first 100 cases. The practice of the clinics with respect to surgery differs considerably and is not important for the purposes of this report. Three of the groups have used the drug solely as a preoperative treatment, three have used it predominantly as a treatment for thyrotoxicosis without surgery and the rest have either varied their practice from time to time or have consistently divided their cases into two groups.

FATALITIES

In table 2 is shown the incidence of fatal outcome during the administration of thiouracil. In the 1,091 treated cases there were eight deaths which occurred during the administration of the drug. A brief account of these deaths follows:

CASE 1.—A person suffering from severe toxic diffuse goiter (metabolic rates starting in the range of + 56) and severe myasthenia gravis developed fever and a severe exacerbation of the myasthenic state on the eleventh day of treatment. The patient died on the following day, a typical myasthenic death. Although the drug may have been responsible for the fever, it is probable that the death should be regarded as a myasthenic death and not a death due to the drug itself, as the fever would probably not have been fatal in a thyrotoxic patient without myasthenia.

CASE 2.—A person with severe myasthenia gravis, who had relatively mild toxic diffuse goiter, was given the drug for two months, at which time death took place, the death being that of fatal myasthenia gravis. There was no leukocyte-depressing action of the drug. This again should not be considered a drug death.

TABLE 2.—*Deaths Under Thiouracil Administration*

Total Cases Treated	Total Deaths		Drug Deaths	
	Number	Per Cent	Number	Per Cent
1,091	8	0.73	5	0.46

CASE 3.—A middle-aged person who had developed a mild neutropenia on thiouracil was continued on the drug with the occurrence of agranulocytosis. This was treated by stopping the drug and administering vigorous systemic therapy. Four days after the polymorphonuclear count began to rise, the patient developed a cerebral thrombosis and died ten days following the cessation of thiouracil therapy. Although the cause of death is mixed in this case, it may be counted as a drug death, as it followed the development of agranulocytosis and was a complication of that condition (table 5, case 13).

CASE 4.—A person with severe arteriosclerotic heart disease, angina pectoris, pernicious anemia and thyrotoxicosis died a cardiac death and at postmortem examination extensive myocardial damage was found, consistent with a long history of coronary disease. Microscopic examination disclosed perivascular infiltrative lesions not unlike those found by Rich[3] following serum sickness and sulfadiazine poisoning and also reported by Marine and Baumann[4] in thiouracil fed rats. The role of thiouracil in this fatal outcome was doubtless of secondary importance in a complex situation, but the histologic changes suggest that tissue sensitivity phenomena may occur during the administration of thiouracil. This case is not considered to be a drug death.

CASE 5.—A woman under treatment with thiouracil for thirty-five days was given a dosage of 0.6 Gm. per day. After an initial period of regulation of her thyrotoxicosis in the hospital she was discharged home to be followed by her physician. After thirty-five days of therapy the patient complained of a sore throat. She died five days later of typical agranulocytosis with agranulocytic angina, despite vigorous treatment instituted after the recognition of the syndrome. This is considered to be a drug death[5] (table 5, case 9).

CASE 6.—This was the third course of thiouracil administered to this thyrotoxic patient during a period of one year. Thirty days following the initiation of thiouracil treatment and while on a dosage of 0.2 Gm. of thiouracil a day, the patient developed a sore throat, followed by a severe shaking chill and a temperature of 103.5 F. Thiouracil was omitted and the patient was hospitalized the following day. On the sixth hospital day the patient died of agranulocytosis. This death is regarded as due to the drug[6] (table 5, case 5).

[2] The collector of these data wishes to express his appreciation to the physicians in these many clinics for their readiness to pool their experiences and data on thiouracil toxicity so that an analysis of the whole series might be accomplished. This provides a more comprehensive survey than could be accomplished by any one clinic alone.

Case 7.—A woman received 65.2 Gm. of thiouracil in fifty-three days, a dosage unusually large because she had previously received iodine treatment and was resistant to thiouracil therapy. Agranulocytosis was diagnosed fifty-seven days after thiouracil was begun and the drug was then stopped. Starting about fourteen days before the thiouracil was stopped, the patient had a furuncle on the nose and about a week later she started to develop a paronychia. Terminally there was bronchopneumonia and a lung abscess. This must be considered a drug death; granulocytopenia was accompanied by widespread infectious manifestations (table 5, case 18).

Case 8.—A woman received 13.8 Gm. of thiouracil in thirty-six days. She was being treated outside the hospital and reported to her private physician with pneumonia and granulocytopenia, which were fatal. This also is considered to be a death due to the drug (table 5, case 10).

These data leave us with a figure for death under thiouracil administration of 0.7 per cent and death directly attributable to the drug of 0.5 per cent.

AGRANULOCYTOSIS

In table 3 is shown the incidence of agranulocytosis during thiouracil therapy. In this table the term "agranulocytosis" is used in the strict sense to mean depressed or absent neutrophilic cells with the concomitant picture of infection, usually around the neck, throat and floor of the mouth. The term is not employed unless the patient showed evidence of agranulocytic "angina" or sepsis elsewhere concomitant with a decided granulocytopenia. There were 19 such cases, the details of which are shown in table 5.

Table 4.—*Incidence of Leukopenia*

Total Series Reporting	Leukopenia	
	Number	Per Cent
781	27	3.4

With the exception of 3 patients who had previous thiouracil therapy, accounting for a possible degree of sensitization, the great majority of these cases of agranulocytosis occurred between four and eight weeks of therapy. There was one delayed case at thirty-six weeks. Of the 19 cases, therefore, 15, or 79 per cent, occurred during the second month of treatment, and 18 out of 19, or 95 per cent, occurred in eight weeks or less after the initiation of treatment. No exact quantitative relationships can be discerned between the total amount of drug employed and the onset of agranulocytosis, as some patients developed severe granulocyte depression on as little as 4.2 Gm. of the drug and others required as much as 65.2 Gm. However, it is important to stress that it is not the total amount of thouracil administered but rather the period over which it has been administered which determines the "period of maximal danger" or "period of maximal neutropenic incidence." This phase, when the patient is most apt to develop a potentially fatal complication, is between four and eight weeks of treatment, and during this stage of therapy the patient should be followed with extreme care. However, it should be emphasized, since the overall spread in the incidence of agranulocytosis runs from two weeks to thirty-six weeks, that throughout treatment the patient must be followed with reasonable clinical precautions.

Previous thiouracil administration tends to hasten the onset of this "period of maximal neutropenic incidence." Four out of 19 cases of agranulocytosis had had previous thiouracil therapy. Therefore, it is conceivable that sensitization by previous administration may at times be an important etiologic factor in the development of agranulocytosis.

As the 5 deaths which were reported as directly attributable to the drug occurred as a result of agranulocytosis, the mortality rate for agranulocytosis is 5 out of 19, or approximately 26 per cent, in this series.[7]

Two patients developed agranulocytosis while on thiouracil and a sulfonamide simultaneously. The avoidance of this combination would appear to be justified as a general policy, since either drug alone may depress leukocyte production.

Table 5.—*Patients Developing Agranulocytosis*

Case	Duration of Treatment	Comment
1	2 weeks	Previous thiouracil therapy; possible agranulocytosis during previous treatment at other institutions
2	2 weeks	Previous thiouracil therapy six months ago; present dose 0.2 Gm. per day; WBC 4,900, PMN 8%; sore mouth; borderline case[8]
3	3 weeks	Previous thiouracil therapy six months ago; present dose 0.2 Gm. per day; WBC 600, granulocytes 0%; severe pharyngeal manifestations, recovered with intensive penicillin therapy after 7 days of complete agranulocytosis[8]
4	4 weeks	Dose 0.6 Gm. per day; WBC 3,100, PMN 0%; typical pharyngeal manifestations
5	4 weeks	Previous thiouracil therapy on two occasions within a year; dose 0.2 Gm. per day, 3 months, first course; 0.2 Gm. per day, 3½ months, second course; present dosage 0.2 Gm. per day; had been discharged from hospital; WBO 1,000, PMN 0%; severe pharyngeal manifestations; bone marrow biopsy showed hypoplastic marrow; died on 6th day of agranulocytosis[6]
6	4 weeks	Patient developed fever and pharyngeal inflammation 8 days after stopping thiouracil; WBC 900, PMN 0%[5]
7	4 weeks	Mild systemic reaction with early agranulocytic angina; WBC 1,600, PMN 7%[5]
8	4 weeks	Angina pectoris treated with thiouracil 0.8 Gm. per day 7 days, 0.6 Gm. per day 18 days, 0.4 Gm. per day 2 days; WBC 2,100, PMN 7%; borderline case[6]
9	5 weeks	Dose 0.6 Gm. per day; had been discharged from hospital; sore throat first symptom; WBC 1,000, PMN 0%; Died on 5th day of disease[5]
10	5 weeks	Dose 0.3 Gm. per day for 25 days, 0.2 Gm. per day for 11 days; pneumonia with concomitant agranulocytosis and agranulocytic angina; fatal outcome
11	6 weeks	Concomitant sulfadiazine therapy for pneumonia; dose 0.9 Gm. per day 40 days, 0.6 Gm. per day 6 days; PMN 0%
12	6 weeks	Dose 0.8 Gm. per day; a 70 year old patient who showed a poor response to thiouracil; also had diabetes mellitus
13	6 weeks	Agranulocytosis apparently successfully treated by stopping the drug and administering intensive therapy; cerebral thrombosis at the time that blood count began to rise; death 10 days following cessation of thiouracil treatment
14	6 weeks	Mild agranulocytosis; recovery[5]
15	6 weeks	0.6 Gm. per day for 14 days, 0.4 Gm. per day for 14 days, 0.2 Gm. per day for 14 days; fever, infected finger; PMN greatly reduced for 7 days (Williams, R. H., and Clute, H. M.: New England J. Med. **230**: 657, 1944)
16	7 weeks	
17	8 weeks	Concomitant sulfathiazole therapy
18	8 weeks	Dose 1.5 Gm. per day for 37 days, 0.6 Gm. per day for 16 days; unusually large dose of thiouracil in patient apparently resistant to treatment; granulocytopenia with angina, furuncle on nose, paronychia, bronchopneumonia, lung abscess; fatal
19	36 weeks	

LEUKOPENIA

In table 4 is shown the incidence of leukopenia during the administration of thiouracil. In this table the term "leukopenia" is used to denote depression of the white cell series without the development of infection around the throat or floor of the mouth or elsewhere and in which the selective depression of the neutrophilic series is not as striking as in the cases of agranulocytosis. This table includes cases only from those series in which the incidence of leukopenia was indicated numerically. Most of the clinics regarded any reduction of white cell count to less than 3,000 as significant. The polymorphonuclear cells were usually somewhat reduced, though rarely below 10 per cent, and in some cases they remained as high as 50 per cent.

---

[7] One additional instance has been reported which is of interest in this connection. The patient received thiouracil for about three weeks and then developed a leukopenia. The drug was stopped and two weeks later she developed granulocytopenia and a *temperature of 106 F.*, with cellulitis and lymphangitis of the finger, extending up to the axilla. During this time, her white blood count fell to 400. She was treated with penicillin and transfusions and ultimately recovered. It is difficult to reconstruct all the events leading up to this situation, but in view of the leukocyte depression produced two weeks previously by thiouracil, one may place the blame for the failure of leukocyte response at least in part on thiouracil. If this is true, it would suggest that any patient who has developed a neutropenia on thiouracil should be followed closely for approximately another month and advised as to the dangers of intercurrent infection.

It is significant that no leukopenias were reported as occurring less than twenty-five days after the initiation of treatment, with the one exception of a patient previously treated with thiouracil without reaction. The majority of the leukopenias occurred at four to six weeks of treatment. In many of these cases the white cell count returned to normal without ceasing administration of the drug. In the majority of them, however, the drug was stopped and again a return to normal without other specific therapy was the rule. It is worth stressing that here again, just as in the agranulocytoses, the "period of maximal leukopenic incidence" is from four to eight weeks after the initiation of treatment.

DRUG FEVER

In table 6 is shown the incidence of drug fevers in this group of cases, and only those series in which the incidence of fever was definitely recorded are included in this tabulation. In all of these cases except 4 the drug was known to be definitely the cause of the fever, usually as demonstrated by the administration of subsequent "pilot" doses. It is of interest that one of these drug fevers, subsequently proved to be due to the drug, occurred only five hours after the initial administration of the drug. This suggests preexistent sensitization from some unknown source, a factor which might, in isolated cases, hasten the onset of leukocyte-depressing reactions also. All of these drug fevers are early manifestations and with only two exceptions they occurred under four weeks of therapy. The dosages employed did not vary significantly between those clinics reporting fevers and those few groups which included a very low incidence or absence of fever. The latter were all small groups of patients in which the laws of probability might be responsible for the reported absence of drug fever.

MISCELLANEOUS REACTIONS

Other toxic reactions of a wide variety were reported from a number of clinics. As previously mentioned, a detailed analysis of these miscellaneous and variable reactions has not been an important part of this joint effort. However, a brief statement of the data which are available is as follows:

Ten cases of lymph node or glandular enlargement were reported in a total of 458 cases in series reporting the presence or absence of this complication. These glandular enlargements included disorders in the various salivary glands as well as the lymph nodes in the neck. One case of thyroiditis was reported. Two cases of acute parotitis were reported in this series. Many of these reactions disappeared with continuance of the drug and none of them was of special severity. One case of "Mikulicz syndrome" was reported with swelling of the parotid glands, the submaxillary glands and the tear glands. Possibly a related phenomenon was the occurrence of conjunctivitis in another patient.

One clinic reported several cases of oral sepsis associated with administration of the drug but unassociated with white cell depression. These were cases of dental abscesses, gingivitis, sore throat and stomatitis without agranulocytosis, which seemed to undergo exacerbations while under treatment with the drug. An exact causal relationship could not always be established. The drug was not stopped in most of the cases.

Various groups reported skin reactions, edema of the feet, jaundice and psychotic manifestations as isolated happenings. Albuminuria in several cases and 1 case of hematuria represent the only renal complications reported. The albuminurias appeared to be of little significance. The hematuria occurred without crystalluria and could have been due to causes other than the drug.

One case of platelet depression to 32,000 with positive Rumpel-Leeds test occurred after twelve days of treatment. The bleeding time was normal, the clotting time increased to 20.5 minutes (Lee and White test). Check platelet counts and smear confirmed this situation. Within forty-eight hours of withdrawal of the drug the platelet count rose to normal levels. Subsequent administration of thiouracil (ten days later) to the same patient failed to alter the platelet count.[8]

The occurrence of mild and occasionally profound myxedema has been observed in patients in whom treatment has been allowed to depress the metabolism to a low level. During this phase, if the patient is prepared for operation with the usual preoperative medication, unusual sensitivity to opiates may be observed which must be regarded as one of the hazards of thiouracil administration.

Two "scleroderma-like" reactions have been observed in which the patient developed tightness of the skin and a sensation of muscle binding. Objectively they showed loss of skin mobility and elasticity, but little else. Both these patients had been treated for sixty-five to seventy-five days and both of them were mildly hypothyroid.[5]

SUMMARY

A joint study of the incidence of severe toxic reactions during thiouracil therapy has been completed by eleven clinics in various parts of the United States and one in England. One thousand and ninety-one patients were treated in these institutions up to the time of reporting their data (which was generally completed about April 15, 1945).

The series reported includes patients treated for periods of from two weeks to two and one-half years. The dosages employed were generally from 0.5 to 0.8 Gm. per day for a period of three to seven weeks or until the basal metabolic rate was normal, following which the dose was either reduced or the patient was operated on. Minor variations in this dosage routine were employed by many of the clinics and do not significantly alter the statistics. The following summary of the data here presented is offered, using round numbers to express incidence:

1. Death under administration of the drug, 0.7 per cent.
2. Death attributable directly to the drug, 0.5 per cent.
3. Agranulocytosis, 1.8 per cent.

---

[8] Barr, D. P.: Thiouracil in the Treatment of Thyrotoxicosis, New York Med. 1: 17, 1945.

4. Death rate in agranulocytosis, 26 per cent.
5. Leukopenia without agranulocytic angina, 3 per cent.
6. Fever, 5 per cent.
7. Glandular enlargement, 5 per cent.
8. Miscellaneous reactions, 2 per cent.

Of these reactions agranulocytic angina, leukopenia and high fever all make cessation of drug administration virtually mandatory. The total incidence of these reactions is between 8 and 10 per cent. These data would indicate that approximately 1 out of 10 patients in whom treatment was started had to have the treatment stopped because of the incidence of a reaction which could not be handled safely without discontinuance of the drug. This is a maximal figure, as some of the leukopenias may be treated with continuance of the drug, although there is some evidence to indicate the possible danger of such a course. On the basis of these figures, approximately 2 out of every 100 patients treated may be expected to develop agranulocytosis. If this reaction is identified and diagnosed immediately and drastic treatment begun, the death rate may be lowered below the figure of 26 per cent observed in this early series of cases. The data here presented lead to the conclusion also that previous thiouracil therapy or concomitant sulfonamide therapy appears to increase the risk of leukocyte depression and therefore enforce careful observation and the utmost caution in the handling of patients.

The treatment of agranulocytosis falls beyond the scope of this report; all those who have had experience with this complication stress that early and adequate penicillin therapy is of the utmost importance in controlling the infectious manifestations.

The most dangerous period from the point of view of leukocyte depression is from four to eight weeks after initiation of treatment. The onset of this period may be lowered to two weeks, if the drug has been administered previously to the same patient, regardless of whether or not there was untoward reaction on the previous occasion. During this "danger period," any patient under treatment with thiouracil should be followed with extreme care and caution, and the isolated incidence of toxic reactions up to nine months of therapy make continued supervision essential.

COMMENT

DR. DAVID P. BARR, New York: It is not apparent that the size of the dose or the method of administration will insure against toxic reactions. It is evident that agranulocytosis will appear with disarming suddenness. It is unlikely that even frequent blood counts will give a sufficient warning. At least equally important is the education of the patient to symptoms which may indicate the beginning of agranulocytosis and a liability to infection. As our study has gone on, we have had to depend more and more on the cooperation of the patient in detecting evidence of toxicity. All will agree that early diagnosis of agranulocytosis is crucial. Our own experience with one case of great severity has suggested to us that a patient may be protected for many days during complete agranulocytosis from overwhelming infection by adequate use of penicillin.

DR. H. P. HIMSWORTH, London: If leukopenia is arbitrarily defined as a level of white blood corpuscles lower than 3,000 per cubic millimeter, then it is quite correct to say that thiouracil does not produce leukopenia in more than a minority of patients. But if the white blood cell count after treatment is compared with the white blood cell count before treatment in the individual patient, it has been our experience that a fall occurs in most cases. In further support of this view is our observation that the Arneth count swings to the left under thiouracil therapy. This depression is related to dosage. With 0.8 Gm per day the white blood count falls. When the dose is lightened to 0.2 or 0.1 Gm. the level rises to approximately the value before treatment. Thereafter a slow decline spread over many months occurs in many patients, although it is only in very few that the level falls ultimately below 3,000. These observations were undertaken in the hope that we might be able to detect potential cases of agranulocytosis before symptoms developed. In this respect they have failed. There has been nothing unusual about the fall in the white cells in those of our cases in which agranulocytosis has developed or in most of those in which leukopenia has developed. In both instances the condition has appeared suddenly and in the former appears to have been related to an intercurrent infection. The practical points which arise from these results are that a fall in white blood cells occurs in most patients under thiouracil therapy and is not necessarily an alarming feature. Routine white blood cell counts should be done on all patients to detect unsuspected leukopenia; but it cannot be assumed that, if the white cell level is normal, the patient will not develop agranulocytosis even in the immediate future. All patients, irrespective of the levels of their white cells, should be instructed to omit thiouracil and report at once if any febrile illness develops.

DR. KARL E. PASCHKIS, Philadelphia: Since this report was submitted we have made further observations which appear of interest. We have observed 2 cases of agranulocytosis other than those described in this report. In both cases there was associated liver damage, as evidenced by jaundice and abnormal sulfobromophthalein retention. Whether the liver damage was a result of the concomitant infection or whether the liver damage played a part in the pathogenesis of the agranulocytosis cannot be decided. Evidence of liver damage was also observed in 2 other patients who had drug fever due to thiouracil but no agranulocytosis. Evidence of liver damage would probably be found more frequently in cases of toxic reaction to the drug, both with and without agranulocytosis, if serum bilirubin determinations and liver function studies were carried out routinely in such cases.

In 2 cases of agranulocytosis recovery followed (1) withdrawal of the drug, (2) treatment with penicillin and (3) administration of crude liver extract and of pyridoxine. We believe that withdrawal of the drug and combating the concomitant infection are essential. How much the adjunct treatment with liver and vitamin B_6 actually contributed to the cure cannot be decided. After recovery both these patients received test doses of thiouracil. One tolerated the drug, whereas the other developed leukopenia and neutropenia.

Another case of interest is that of a man with thyrotoxicosis recurring ten years after subtotal thyroidectomy. On admisssion he had a leukopenia of 2,500 to 3,000, with 35 to 39 per cent of polymorphonuclears. Review of his previous hospital record showed that the leukopenia had been present at the time of the original thyroidectomy (ten years before). Thiouracil has been tolerated by this patient, his blood count and bone marrow showing no appreciable change on repeated examination over a period of five months.

Effects of Closed Cranial Injuries.—The clinical effects of injury to the upper brain stem are not always to be clearly distinguished. In the cases with short survival periods, the specific symptoms and signs pointing to a disturbance of functions of this region are obscured by traumatic shock, by deep coma and by the effects of other associated lesions of the brain. Particularly in the case of unilateral distorting lesions with longer survival periods, the progressive development of unilateral motor signs and deepening stupor also befog the situation until late in the progress of the intracranial situation when the vital centers begin to fail. Nevertheless, the alert and persistent examiner can often find evidences of such disturbances. These symptoms may be divided into three groups: those referable to the vital functions (maintenance of respiratory and circulatory functions), pupillary changes and motor symptoms. Since the pupillary changes are but incidental, the essential syndromes will concern the vital and motor functions.—Courvill, Cyril B.: Effects of Closed Cranial Injuries on the Midbrain and Upper Pons, in Trauma of the Central Nervous System, Baltimore, Williams & Wilkins Company, 1945.

CHRONIC BRUCELLOSIS: SUCCESS OF TREATMENT WITH BRUCELLIN

HENRY M. BENNING, M.D.
Santa Barbara, Calif.

Pasteurization of every drop of milk produced today would effectively reduce to the minimum tomorrow's new cases of brucellosis in all but the few occupations concerned with handling of infected animals. However, if such a forward step could be taken to protect the general population now, it would scarcely affect thousands of persons who drank raw milk several years ago. Eradication of infection in dairy herds to prevent new cases presents many difficulties. The diagnosis and treatment of thousands of old chronic cases presents many more problems. Of course pasteurization is not yet universal. Travel between the states has increased since 1941. Early in the mobilization after Pearl Harbor certain training units in the field were obliged to purchase food for mess, including raw milk, wherever it could be found. Officers and men could thus easily have contracted brucellosis while in service. Then and now they are still unprotected from possible exposure while on furlough.

Actually the dairy industry is hard at work to eliminate brucellosis in milk producing animals, even while all such milk products are requisitioned by a wartime economy. Nearly 40,000 calves were vaccinated in the United States in the one month of April 1944. During the same month over 13,000 cattle slaughtered had been found previously to be positive reactors by blood test.[1]

Meanwhile members of the profession everywhere, both civilian and military, must remain alert to an infection especially of the milder chronic type whose beginning is so often masked or insidious. Repeated attention has been called to the appearance in this country of the more dramatic acute febrile forms of infection. It was the presentation sixteen years ago by Simpson and Frazier[2] which was directed to the largest medical audience and summarized the problem well. Yearly increases of reported cases followed. The diagnosis in such a protean disease must at any time be considered by the internist, gastroenterologist, orthopedist, neuropsychiatrist or general practitioner.

Extended use of the means of detection are being made. An appraisal of the diagnostic methods (1) clinical history, (2) blood culture, (3) serum agglutination, (4) opsonic index and especially (5) the intradermal skin test, together with (6) the therapeutic test, is my purpose in this paper.

The prevalence by survey of latent, subclinical forms of brucellosis is astonishingly high. Reasonable doubt that the health problem so represented is indeed serious might be entertained if the efficacy of tests used in such a survey could be questioned or if such figures indicated merely active immunity. But in truth a most widely disseminated, highly invasive and extremely tenacious organism is concerned. Therefore a mammoth reservoir of potential danger to national health and efficiency is at hand.

Angle[3] found the incidence by skin test in 7,122 school children to be 9 per cent. The high was actually 18 per cent in the group of 711 oldest children and among those who came largely from families which kept cows of their own. It was lowest, 1 to 2 per cent, in the Negro families which bought milk in bottles at stores. Although city dwellers are indeed often exposed, rural populations are in greatest danger. There are 57,245,000 persons living in small towns and in rural areas of the United States. Nine or even 1 per cent of such a population total, or that of any one of the several states, produces an impressive figure. Among these must certainly be some who are immune, but the rest may be ill at this time or, since the disease can last a lifetime, destined to develop symptoms at some future date. It will appear from this study that such high percentages are not absurd but reflect the tenacity of Brucella (chiefly the abortus variety), and that suffering and time lost by illness is great, but that treatment is effective if the cause is recognized.

Bacteremia may be demonstrated early in the course of many cases with fever, but the diagnosis rests chiefly on serologic and skin tests, especially in the chronic state. Blood culture requires special mediums held beneath atmospheres of 15 to 20 per cent carbon dioxide. Rarely is blood culture found positive in the chronically ill, but the significance in any case is obvious. The opsonophagocytic index is a somewhat difficult and rather needless laboratory aid for routine use.

Agglutinins begin to appear several days to several weeks after onset. For the physician the agglutination test is simply a matter of drawing blood as for a Widal or Kahn test, this to be sent to a competent laboratory. The titer in the serum may reach a height of 1:5,000 but is roughly proportional to the highest recorded elevation of temperature between 99 and 105 F. Attention must be paid to low titers, and anything above 1:40 is diagnostic. Specificity of the test is high, with false positives almost nil, the only important cross agglutination being in tularemia. Sensitivity is not very high, however, at least in relation to the antigen in use at present. Agglutination has been found negative at times when the blood culture was positive. Agglutinins if present at the onset often disappear as the infection persists, so that negatives result in at least 46 per cent of the chronically affected according to Evans,[4] and in 86 per cent according to Huddleson.[5] Such results almost invalidate the test as a diagnostic measure in the ambulatory case.

The peculiarities of the proteins of the brucella cell structure must account for the inconsistencies of the agglutinin response on single tests. Heat stable endotoxin comprises roughly 25 per cent of the cell and is accompanied by a relatively large amount of toxin enhancing lipoid. The endotoxin in man as in experimental animals produces the systemic effects of hyperglycemia followed by hypoglycemia; elevated, then lowered basal metabolism; leukopenia; subnormal temperature, and so on. This endotoxin appears to stimulate as an antigen little if any antibody. The low antigenicity may largely account for the ability of the organism to live on unharmed by the host. Brucellosis cannot be said to be self limiting.

The function of the intradermal test is to detect the presence of endotoxin in the circulation. Skin sensitivity, after bacteremia and agglutinin response, if any, is the last to appear and the last to disappear. By the

time infection has lasted several weeks, but occasionally only after many months, certain "preparatory" changes take place in the endothelium of capillaries in the skin. (Similar allergic changes doubtless occur in other tissues as a result of alteration by, or combination with, brucella protein.) Injection thereafter of homologous protein outside the endothelial wall is followed by inflammatory changes: capillary dilatation, edema and redness, together with varying degrees of general reaction. This happens only provided homologous bacterial protein is still circulating inside these capillary walls. The patient's skin is the test tube in which conjunction of protein takes place. Thus a positive reaction signifies the continued presence of bacterial derivatives in the body regardless of whether they have or will produce recognizable symptoms. A negative test means simply skin anergy, or that no bacterial derivatives remain. Such properties of bacteria were studied by Hanger [6] and Shwartzman [7] almost simultaneously, and the "specific bacterial skin effect" observed became known as the Shwartzman phenomenon. There are of course certain quantitative limits within which the reaction is visible short of skin necrosis. As for time limits and preparatory factors it is necessary that active infection be established. The maximum reaction is reached at forty-eight hours. The class of proteins comprising animal and food allergens behaves quite differently.

Brucellergen (Huddleson,[5] p. 244) is standardized on rabbits after thirty days following inoculation with live cultures. This material for skin testing is an improvement over the earlier use of bacterial filtrates and cell suspensions. These were mixed proteins. Brucellergen is a protein nucleate solution, the test dose being 0.00075 mg. in 0.1 cc. This is 625 times the quantity of mixed protein contained in 2,000,000 brucella cells, a number used previously for skin tests. Severe skin reactions are obviated by the use of nucleoprotein. Sensitivity is moreover so high as to permit detection of at least 95 per cent of chronic cases. Thus false negatives are only 5 per cent at most, except in early cases. False positives, on the other hand, are reduced to zero and specificity is 100 per cent, since the single nucleoprotein does not react with products of common bacterial cells other than brucella. Actually it is possible to go a step further in interpreting a positive reaction than to conclude merely that brucella endotoxin is circulating. Gay [8] states that many bacterial endotoxins are incapable of giving rise to neutralizing antibodies but may give rise to antibodies reacting with the nucleoprotein. In a small trial series precipitin reactions between serum of skin positives and brucellergen were obtained by us in a dilution of the latter as high as 1 : 6,400. Skin negatives did not react. Thus the positive skin test could mean a conjunction of nucleoprotein and antiendotoxin. This explanation as a working hypothesis would satisfy every clinical situation, especially the positive test in the asymptomatic, not to mention the decreasingly intense positives in the treated patient who is recovering. The necessity of active infection as a prerequisite to the establishment of skin sensitivity rules out the one other possibility that the patient merely has been swallowing endotoxin in pasteurized milk. Data on the unimportance of swallowed dead brucella in symptom formation will be published later.

The significance of a positive brucellergen skin test has been compared to that of a positive tuberculin test. This has led to misunderstanding, since so many of the latter positives have been shown to be inactive cases. The two diseases should be contrasted rather than compared. Most important, it should be remembered that in either case the practical conclusion immediately on reading a positive is to assume that the patient has an active infection until proved otherwise. Only a careful study of either patient will finally determine whether infection is subsiding or is still active. Repeated skin tests in brucellosis after a waiting period may be used when there is doubt. The characteristic symptom complex rather than x-ray or physical findings must be relied on.

The clinical picture of chronic brucellosis or the walking patient has been adequately described in monographs [9] and in the recent reviews of Manchester,[10] Griggs [11] and many others. Perhaps the description of Evans [12] was most succinct when she compared it to "neurasthenia." She challenged the right of application of this label, and by inference that of psychoneurosis, unless chronic brucellosis was first ruled out. Since undulate they will, the symptoms are usually variable in that they alternate with well periods. In psychoneurosis actually there is a great deal more consistency. There is no fever. The aching seems to the observer to be vague, unrelated to organs or to gross anatomy. Physical examinations are negative and blood findings normal. X-ray studies are without objective architectural changes. The physician's credulity is often taxed to the point of annoyance. He becomes tempted to explain peculiar functional derangements by a term which is not synonymous with functional, namely "psychogenic." The very nature of the toxemia in this infection contributes to an invalidism, which, combined with the feeling of frustration in the years spent trying to regain health, does convey the impression of primary psychoneurosis. To differentiate conversion formation from organic reaction, psychiatric consultation is not always readily available. The busy practitioner should therefore welcome such a dependable procedure as the simple skin test. Its application may become as routine as the Kahn in the future; certainly it is indicated in any case of fatigability with muscle pains, bizarre nervousness or atypical dyspepsia.

Although no attempt will be made to discuss other forms of treatment, any method should take into account the peculiar properties of the bacterial cell involved. Brucella cultures differentiate into various rough, smooth, mucoid, virulent and nonvirulent forms. Some have a thin capsule and some have no demonstrable capsule.[13] The only consistent feature of brucella is the extraordinary versatility or adaptability of the microorganism to growth in animal tissues. For the most part the tissue changes produced are reversible, symptoms being on a chemical rather than structural basis. The pathology of brucellosis is well established, but that small foci of active infection may remain undetected during life in spleen, gallbladder, liver or lymph node seems plausible enough to be assumed in a given case.

If these foci are found, surgical removal would be the treatment of choice. If not found, medical management remains.

The antigen responsible for producing immunity in animals is extremely labile, being affected both by heat and by chemicals. Only the unaltered living organism produces immunity on vaccination, although Huddleson[14] has succeeded in protecting guinea pigs with a ground cell suspension in which the labile material persists. The 40,000 calves mentioned were given the attentuated culture known as strain No. 19. As yet there is not available for human use a vaccine whose toxicity is decreased and whose antigenic qualities are unmodified or enhanced. The injection of billions of heat killed cells (bacterins) has nothing to commend it in theory or in practice.

Brucellin, as prepared by Huddleson,[15] is a culture filtrate without bacterial cells. Reports of its use are not numerous, especially in a series of ambulatory cases. Used in Malta, in a controlled series of acute forms, it shortened the duration of infection considerably in 82 per cent of cases. Whereas old tuberculin is a glycerin broth, brucellin is a beef liver infusion on which virulent smooth strains of melitensis, suis and abortus have grown for three months. After filtration and sterility tests, 0.5 per cent phenol is added. It contains no endotoxin. After administration in the infected, the "negative phase" with exaggeration of all symptoms is but temporary. The active principle or antigen in such a protein mixture by its very nature defies more exact chemical description but seems to be a nucleoprotein (not identical with brucellergen). At any rate immune response is encouraged, since there is elevation of temperature and perhaps a creation of (neutralizing ?) antibodies.

TABLE 1.—*Results of 1,065 Skin Tests*

Total past or present infection	146
Positive skin test	141 (13.2%)
Negative skin	5 (3.4%)
Treated with	97
Brucellin plus	4
Heat killed vaccine	5
Refused treatment	4
Not treated	36 (25%)

CLINICAL MATERIAL

The brucellergin skin test has been performed on over 1,800 clinic and hospital patients during the past two years, until it has become an almost routine procedure. Results of the first 1,065 tests done between March 6, 1943 and Dec. 6, 1944 are given in table 1. No skin necroses were produced even with the full dosage, although several showed intense vesiculation. Of the original group of 146 cases in which the diagnosis of past or present infection was made, no specific treatment was given in 36, or 25 per cent. It is probable that several of these should have been treated, in the light of present knowledge. Seven persons who returned one year later and who had a second positive skin test are included in the first series of 97 treated. Only a small fraction of positives are not given specific treatment at this time, a few of course having as serious a coincident pathologic condition as carcinoma for contraindication.

A detailed clinical history was taken and physical examination with tentative diagnosis was made on admission. All laboratory and x-ray studies then proceeded while the result of the skin test was being awaited. Effort to elicit definite history of raw milk consumption or contact with infected herds was met with success a few times, but denial of exposure obviously had no value. All occupations were represented. Sexes were almost equal. Ages were predominantly in the forties. One, a boy of 13, had a seven year history and previous ineffective treatment with bacterins. Several persons were past 65. Average duration of symptoms, excluding 1 case of three months and 1 of twenty-eight years, was slightly over three years. Chief complaints were as reported by others: (1) fatigability, (2) aches and pains, (3) nervousness and (4) indigestion, dyspepsia, bilious spells, bloating and constipation. Abnormal fatigue was invariably listed in every history, but one of the other symptoms often held sufficient prominence to be mentioned first.

THE SANSUM CLINIC
SCHEDULE AND RECORD
for BRUCELLIN Injections

Name..

No. Date: Dose: Route: Reactions...............
Fever ?

1 .... 0.05 cc. or .... cc. intradermal ....
2 .... *0.10* cc. or .... cc. subcutaneous..................................
3 .... *0.15* cc. or .... cc. subcutaneous or intramuscular...........
4 .... *0.20* cc. or .... cc. *subcutaneous or intramuscular*...........
5 .... *0.25* cc. or .... cc. subcutaneous *or intramuscular*...........

A report to the doctor by letter or phone is suggested here.

6 .... *0.30 cc. or* .... cc. ....
7 .... *0.35 cc. or* .... cc. ....
8 .... 0.40 cc. or .... cc. ....
9 .... 0.45 cc. or .... cc. ....
10 .... *0.50 cc. or* .... cc. ....

Reactions expected are chills, temperature *rise of 2 to 4* degrees with exaggerations of symptoms as aching, *indigestion or constipation*, these subsiding in one to three days.

Liberal use of aspirin, *fruit juices and light carbohydrate* midmeal feedings suggested.

As the number of injections *increase the degree of systemic reactions decreases until at the* end of eight to fifteen injections there is almost no reaction except local redness. *A rest period of two months may be* taken then, a second course with the *first small injections of 0.1 cc. or less being repeated if* symptoms have again arisen.

Skin test to determine the presence of circulating *endotoxin antigen* by means of nucleoprotein, "brucellergen," *may be done two, three* or six months after the final injection.

....M.D.

Date....................194.....

Afternoon admission temperatures were usually normal or slightly subnormal but in one third of the cases were between 99.2 and 99.8 F. In a single instance of daily fever for three years the temperature was 100 F. This patient was skin negative, but there was positive serum agglutination in a dilution of 1:320. She became skin positive six months after treatment began, the degree of reaction declining in subsequent tests after improvement. Weight was normal in half the cases, below normal 10 to 20 pounds in one fourth and above normal in the remainder.

Physical examinations were without objective findings except the occasional mention of reddened eyelids or sallow complexion. Attempts to palpate enlargement of the spleen met with success in but 2 cases. Sedimentation rates were usually normal. Basal rates were usually slightly below normal. Blood tests for agglutination were kept at a minimum to avoid taxing available laboratory facilities. In a group of 75 patients the agglutination was positive in only 24, or 32 per cent, and the titer only 1:25 in 4 of these. Thus the percentage of frank positives was only 26. Blood culture done on a number of occasions was invariably negative. Opsonophagocytic indexes were omitted as too time consuming if not actually superfluous.

[15] Huddleson: Brucellosis in Man and Animals, pp. 141, 154 and 162.

Since many patients did not reside in the city, these were supplied with brucellin and given a printed schedule of suggested dosage for the physician's use at home. Seventeen persons received all injections at the clinic. The initial dose was 0.05 to 0.1 cc., depending on the severity of the skin test reaction, and this initial dose given intradermally determined the patient's reactive ability. Very rarely was it necessary to dilute the brucellin. The patient was warned that he might expect a chill, fever, and an exaggeration of his symptoms. This appeared in eight to twelve hours after a subcutaneous and within four hours after an intramuscular injection. Reaction symptoms subsided in two or three days and decreased in severity as the number of injections increased. When almost no systemic reaction was obtained after a series of perhaps ten to twelve weekly injections a rest period was advised. The level of immunity so obtained was sufficient to neutralize subsequent, now milder, attacks, but repeated courses of brucellin were given if symptoms recurred instead of decreasing. One course would last two to six months, after which subsequent skin tests were performed when possible, a positive test being followed by additional injections if symptoms persisted.

REPORT OF CASES

Case 1.—B. L., a man aged 43, a dock foreman, whose weight was 235 pounds (117 Kg.) and height 75 inches (191 cm.), was admitted to the Sansum Clinic Aug. 10, 1943 with the chief complaint of tiredness for three years. Several days at a time he would feel quite well but suddenly again would feel "terrible." He explained each attack of abdominal pain or soreness as if the food did not digest but stopped in the stomach, causing bloating and constipation. During attacks he became irritable, short tempered and worried over minor problems. Three years previously he had had "flu" most of one winter, with congestion in his chest, and he said he "could hardly drag around" at night. Six months afterward there appeared a mild degree of jaundice without pain but with extreme fatigue. Muscular effort later began to be followed by chills and then fever. There had been occasional dry hacking cough since the jaundice, recurrent constipation, occasional difficulty in starting the urinary stream and a decline in sexual potency. The generalized urticaria of recent months was slightly relieved, he thought, by following advice to omit all milk. He had consumed raw milk by preference, obtained from a large metropolitan dairy three years previously and to a lesser extent since.

The admission afternoon temperature was 98.6 F. Physical examination revealed that the patient was well built with a few scattered large urticarial wheals on the skin, slightly reddened eyelids and dry lips. There was slight tenderness over the gallbladder, cecum and transverse colon. The abdominal reflexes were absent. His blood pressure was 150/88.

Blood count was 5,380,000 red cells, 17 Gm. or 108 per cent hemoglobin and 6,900 white cells with 63 per cent polymorphonuclears. The icterus index was 10.5, the Kahn reaction negative, brucella agglutination positive in a 1:50 dilution. Fasting blood sugar and four hour oral glucose tolerance readings were 82, 102, 106, 96 and 72 mg. per hundred cubic centimeters respectively. Urinalysis was normal. An Ewald test meal showed free acid of 25 degrees with a total acid of 30 degrees. Gallbladder studies after Priodex orally showed excellent filling with the dye, only 30 per cent emptying, and three small opaque stones 3 mm. in diameter in the fundus. Only 0.08 cc. of brucellergen was used for the skin test. The reaction was 5 plus in forty-eight hours with general reaction and a wheal measuring 5 by 10 cm.

Brucellin was given every two weeks by us in the clinic. The first injection of 0.05 cc., intradermally, was followed in ten hours by a chill and a temperature of 102 F. Next morning it was 99.8 F., rising in the evening to 101 F. Although headache and prostration were severe the patient was feeling much better by the fourth day. After the second injection of 0.1 cc. subcutaneously there was a chill, rise in temperature to 101 F. by morning and 103 F. by evening and then a drenching sweat. He was unable to work for five days. His eyes were red and swollen; of all symptoms the indigestion and the urticaria were the most severe. The second week he improved. Reactions gradually became less troublesome; urticaria disappeared. To the tenth injection of 0.6 cc. there was no reaction. Three weeks later, Dec. 26, 1943, he appeared for examination stating that he "felt like a million dollars." He had declined a gallbladder operation. Nine months after recovery he was still working and had no complaints. At eleven months there occurred an attack of indigestion again. Dec. 26, 1944 a skin test was 3 plus, without general reaction. He immediately began a course of brucellin, reacting only to the first dose in a series of five injections. He then had a cholecystectomy performed by his family physician, Dr. Walter Boyd of Long Beach, Calif., March 18, 1945. He made a rapid recovery from the operation.

The foregoing could be called the textbook description of chronic brucellosis with a full recital of symptoms referable to all tissues. Treatment reactions are typical. It also illustrates probably the most common route of invasion (jejunal mucosa, lacteals, liver) and focal point for persistence of infection. This focus can be held almost completely in abeyance for many months only to light up again suddenly.

Case 2.—J. T., a man aged 54, a salesman, whose weight was 173 pounds (78.5 Kg.) and height 66 inches (168 cm.) was admitted to the clinic Sept. 1, 1943 complaining of burning pain in the chest for one year. Onset was gradual with heartburn and stomachache, worse since a severe head cold three months before. The pain, which was now unremitting, was localized just to the right of the sternum. He was unable to walk a block without feeling so weak as to be able barely to stand; he had become slightly yellow he thought; he did not perspire; his heart pounded on exertion. He had drunk goat's milk three months previously at a neighbor's suggestion but recalled having not felt well for at least two years.

On admission the temperature was 98.6 F. Physical examination revealed that the patient was overweight, not dyspneic but looking chronically ill. The skin was dry and pale, with numerous small patches of psoriasis. The heart tones were of only fair quality; there were no murmurs; the rate was 104, regular. There was very slight tenderness over the gallbladder. The blood count was 6,250,000 red cells, hemoglobin 16.5 Gm. or 103 per cent, and 11,100 white cells with 64 per cent polymorphonuclears. The Kahn reaction was negative. The fasting blood sugar was 136 mg., the blood uric acid 1.9 mg. and serum cholesterol 310 mg. per hundred cubic centimeters. An electrocardiogram showed a deep Q_3 equal to R_3 with T_3 sharply inverted. The brucellergen skin test was 4 plus. Agglutination was negative, December 20.

He was placed on a reducing diet without insulin, aminophylline 3 grains (0.2 Gm.) every four hours and brucellin every two weeks. Little reaction and no relief of pain followed the first few doses, but to the seventh injection of 0.45 cc. the response was a temperature of 103 F. During this time he developed a generalized eczematous dermatitis, but the constant chest pain gradually disappeared. Feb. 1, 1944, four months after treatment began, he stated that he was "100 per cent well." He resumed traveling. He received three courses of brucellin, twelve, six and four doses. Each course followed a skin test progressively less positive. Fourteen months after admission the skin test was entirely negative. Three subsequent electrocardiograms made Dec. 20, 1943, Aug. 14, 1944 and Feb. 23, 1945 were essentially the same as on admission, with minor temporary improvements in Q_3 and T_3, but the patient appeared well, had no pain, and felt no fatigue. The dermatitis disappeared slowly but completely.

This patient still has coronary disease and he has been advised to regulate his life accordingly. The added burden of infection has apparently been removed.

Case 3.—J. B., a woman aged 52, a housewife, was first admitted to the Cottage Hospital Oct. 31, 1930, at which time she complained of attacks of stomach trouble, constipation, nervousness, headaches, dizziness and palpitation of one year's duration. Alternating with well periods these "bilious attacks" produced epigastric pain together with exaggeration of many other complaints, including a feeling of pins and needles in the extremities. Physical and laboratory examinations at that time were not remarkable, and complete x-ray studies of the gallbladder and gastrointestinal tract were negative. Temperature readings above normal on four occasions during thirty days' hospitalization were only 99.2, 99.4, 99.6 and 99.8 F. The second admission nearly fourteen years later was June 15, 1944. There were exactly the same complaints with emphasis on constipation and insomnia, and they were almost continuous. Her constant fretting in the hospital now made life miserable for the nurses, who tolerated her spoiled child attitudes only because they also knew she wept for her only son as a prisoner on Bataan. She had little desire for food but was only 7 pounds (3.2 Kg.) underweight, as compared to 15 pounds (6.8 Kg.) on the previous admission. Gallbladder, stomach, small bowel, and colon x-ray studies were again negative. The brucellergen skin test June 20, 1944 was 2 plus in twenty-four hours and 4 plus at forty-eight hours, with a slight general reaction. Agglutination was negative.

Table 2.—*Results of Brucellin Treatment*

	Number	Per Cent
Unimproved	8	10.3
Moderately improved	22	28.2
Greatly improved	48	61.5
Total	78	100.0

To the first dose of brucellin, 0.1 cc., she reacted with a temperature of 100.4 F. Headache was increased. One week later she was sleeping better and seemed cheerful. She was discharged June 29, 1944, and the injections were given at home by her physician. She telephoned every week and returned on two occasions to report that the injections, nine in all, produced decreasing reactions and that she felt perfectly well and took no sedatives or laxatives. She wanted to apologize to the nurses for the way she acted in the hospital. Her cheerfulness amazed and delighted her friends. Ten months later, April 15, 1945, she telephoned to say she was having some aching pain in her legs. She was advised to take a small course of brucellin and reported after the third dose that only the first injection produced any reaction, that she now felt very well and that she had gained 15 pounds since the beginning of treatment.

It is amazing that symptoms should persist for fifteen years without increasing appreciably in severity but only in frequency. There was ample reason for her to appear psychoneurotic. The melancholia, which might have been called involutional, reached even to suicidal notions. The situation is now quite reversed in that she holds up her husband in their grief over the loss of their son.

Case 4.—E. W., a man aged 65, a butler, entered the Cottage Hospital Oct. 10, 1943 complaining of a swollen right knee for several weeks. He walked with a cane, but there was relatively little actual pain and no tenderness in the one joint area. He weighed 240 pounds (109 Kg.). The temperature was normal. His blood pressure was 156/90. X-ray of the knee was negative, as was a gallbladder study. Blood count was 4,020,000 red cells with 90 per cent hemoglobin, and 9,150 white cells with 63 per cent polymorphonuclears. The sedimentation rate was 6 mm. in one hour. The serum cholesterol was 286 mg., the blood uric acid 3.8 mg. The basal metabolic rate was plus 8. The electrocardiogram showed left axis shift. Twenty-four hours after the brucellergen skin test the knee was much worse; at forty-eight hours the skin reaction was 4 plus, but he felt better. An Ace bandage was applied to the knee. Brucellin was begun October 28 with a dose of 0.1 cc. He returned in a week believing that the knee would have to be opened on the outer side, where there was increased swelling and a red area measuring about 5 by 10 cm. There was no fluctuation. Brucellin was increased, and after the third injection the strength and flexibility of the knee had improved. He walked without a cane after two more and then received a total of only seven injections, the highest single dose being 0.9 cc.

This shows in a local area what may occur on a larger scale at the origins or the insertions of muscles, explaining in part the muscular weakness and disability so common in this infection.

RESULTS OF TREATMENT

Of the 97 patients treated with brucellin all but 19 have completed at least one course of injections, responded to follow-up inquiry or returned for examination and have gone at least six months without return of symptoms. Results are given in table 2. Three of the eight listed as failures discontinued treatment after five injections. One was unchanged after fifty injections.

Twenty-two of the 78 persons followed, or 28 per cent, were moderately improved. One was diabetic, 1 hypertensive, and 1 a chronic alcoholic addict. If some may have broken off treatment too soon because of early severe and unpleasant systemic reactions, others probably reacted too mildly to insure the production of higher immunity. All in this group were, as the adjective implies, improved in definite measure but without achieving the enthusiasm or self assurance of improvement shared by the next group. Search for hidden persistent foci perhaps should be most diligently made in the moderately improved case, and even more simplified easily controlled means of therapy welcomed.

Forty-eight of the 78 persons treated, or 61 per cent, were greatly improved. This included 6 whose skin tests after treatment and a waiting period were negative and might be listed as "cured." Most of these patients reacted violently to early injections and made an immediate improvement, which steadily increased until such a time as there was no longer any doubt in their own minds that they were well. Recurrences in this group might not be expected until several months had elapsed, but only by a plan of constant checkup of skin reaction could this be controlled. Such a plan is being followed.

COMMENT

Nearly as many additional cases as in this first series are being treated at this time. Results are substantially the same. Irradiation of abdominal lymph nodes or the spleen has been done in those cases whose level of immunity does not rise rapidly as evidenced by weak febrile response to early injections of brucellin or to later "booster" doses. A report of the results in these cases will appear later. Data are being accumulated from findings at exploratory operation for coincident pathologic conditions which may throw some light on the location and size of focal areas of chronic infection. So far the evidence of visible and palpable pathologic change is so meager as to inculpate the spleen, whose smooth surface may conceal small abscesses within, as much as the gallbladder, which may carry the organism in its reservoir. Possibly splenectomy should be contemplated as often as cholecystectomy.

Exactly how brucellin works and of what immunity in brucellosis consists cannot yet be stated with certainty. As a protein solution it doubtless gives rise to certain antibodies. The procedure is not a matter simply of desensitization. The hypothesis that brucellin antibodies neutralize endotoxin and hold in check the growth of brucella is at least practical in that it describes the changes taking place in the improved case. This improvement is sufficiently rapid in a high enough percentage of cases to serve as another aid in the diagnosis of the cause of elusive, enigmatic symptoms, which, however real to the patient, may otherwise be only a riddle to the most careful consultant. Complete cure finally may have to wait on additional even untried methods of treatment.

SUMMARY AND CONCLUSIONS

1. Brucellosis is one of the most prevalent of modern diseases.
2. The intradermal skin test is the most reliable means of confirming the clinical diagnosis of chronic brucellosis.
3. Of 1,065 persons tested, 13.2 per cent showed a positive reaction to brucella nucleoprotein.
4. Seventy-five per cent of all positives in this series were considered to have persistent infection and were actively treated.
5. Of 97 cases treated with "brucellin," 78 were followed adequately, with 70 cases improved and 8 unimproved.
6. The skin test should be repeated every six months with the expectation that only a negative reaction denotes a cure.

RANGE OF BLOOD PRESSURE IN HYPERTENSION

RICHARD GUBNER, M.D., FELIX SILVERSTONE, M.D.
and
HARRY E. UNGERLEIDER, M.D.
New York

The variability of the blood pressure poses numerous problems in the evaluation of subjects with hypertension. Thus, in estimating prognosis and the response to treatment, and in examining candidates for military service or insurance, it is well recognized that casual readings of the blood pressure may be misleading. Numerous reports have called attention to the lability of the blood pressure in hypertensive subjects.[1] It is our purpose in this report to emphasize the desirability of recording the blood pressure, particularly in hypertensive subjects, in terms of maximum and minimum range rather than as an individual reading, and to suggest a simple procedure whereby this may be accomplished.

As mentioned in a previous report in THE JOURNAL,[2] various pressor and depressor agents have been employed to study blood pressure responses in normal persons and in hypertension. The rise in blood pressure has been investigated following tyramine, epinephrine, pitressin, tobacco smoking, physical work, painful and irritant stimuli, exercise of muscles with circulation arrested, prostatic massage, immersion of the hands in cold water, anoxemia, inhalation of carbon dioxide and breath holding.[3] Methods employed to provoke a fall in blood pressure include oral barbiturates such as barbital, and sodium amytal, intravenous pentothal, hyperventilation, carotid sinus pressure, histamine, acetyl-beta-methylcholine, amyl nitrite, sodium nitrite, spinal anesthesia and bed rest for a period of twenty-four hours with observations during sleep.[4]

Most of these procedures are not well suited for routine clinical use. The cold pressor test has been widely employed to detect a "prehypertensive state," an exaggerated rise above the initial level supposedly indicating a constitutional predisposition to hypertension.[5] The validity of this interpretation has been questioned,[6] but pressor tests are useful as a measure of a person's "ceiling" blood pressure level. The simplest of the pressor tests is breath holding, and of the depressor procedures hyperventilation and carotid sinus pressure. Whereas breath holding raises the blood pressure, hyperventilation causes a fall.[7] Pressure on the carotid sinus likewise decreases the level of the blood pressure, particularly in hypertensive subjects.[8] A study was carried out in 30 cases of essential hypertension to determine the practical utility of these tests.

In each case the pressor effect of breath holding was compared with the cold pressor test; and the depressor response to hyperventilation, pressure above the carotid sinus and combined hyperventilation plus carotid pressure was compared with the effect of 9 grains (0.6 Gm.) of sodium amytal given hourly in 3 grain (0.2 Gm.) doses as recommended by Allen and Adson.[9] Comparison was made also with the maximum and minimum arterial pressures recorded during the period of hospitalization. In 18 cases, including 13 from the aforementioned series, further investigation was made of the pressor response to brief inhalation of aromatic spirit of ammonia compared to the breath holding pressor response.

The technic employed in the breath holding and hyperventilation tests was as follows: At the end of a normal expiration the subject was instructed to stop breathing without straining. After twenty seconds of apnea the highest systolic pressure was recorded. The subject was then permitted to breathe normally for a few moments and the test was again repeated, this time

(Footnotes continued on next page)

the highest diastolic level being recorded after twenty seconds of apnea. Most persons find it difficult to refrain from breathing for more than thirty seconds when respiration is suspended in expiration, and because of the rapid changes in blood pressure it is preferable to observe the systolic and diastolic rise on separate tests. Because of the difficulty some persons, particularly older subjects, experience in maintaining apnea for sufficient time to record blood pressure changes, an additional simple pressor test was employed. A piece of gauze saturated with aromatic spirit of ammonia was held over the nose, and the blood pressure was determined during brief inhalations of this irritant. This test has an advantage over the breath holding test in that it does not require cooperation, and the pressor response is not so transient as with the breath holding test, so that the rise in blood pressure may be more accurately recorded.

TABLE 1.—*Average Blood Pressure Responses in Thirty Cases of Essential Hypertension*

Routine Readings During Hospitalization	Initial Reading	High	Low	Change from Initial Reading: Systolic	Change from Initial Reading: Diastolic
		208/124	174/104		
Breath holding	181/110	208/133	....	+27	+23
Cold pressor test	187/112	211/130	....	+24	+18
Hyperventilation	187/114	....	171/103	—16	—11
Carotid pressure	190/116	....	169/101	—21	—15
Hyperventilation plus carotid pressure	187/113	....	157/ 94	—30	—19
Sodium amytal	189/114	....	151/ 97	—38	—17

After performing the pressor test the subject was instructed to breathe maximally with deep inhalations and exhalations at a slightly rapid rate without effort or straining. The blood pressure was recorded after thirty to sixty seconds of hyperventilation. With the patient still breathing deeply, digital pressure was applied over the carotid sinus, preferably the left, and the lowest blood pressure attained during the next half minute was recorded. The patient should be apprised as to the nature of the carotid pressure test before it is carried out, so that a psychic reaction to neck pressure is avoided. The depressor response following carotid sinus pressure occasionally persists for several minutes, and therefore the pressor response should be tested first. The maximum and minimum levels attained during the pressor and depressor tests are recorded, e. g. as 208/133-157/94. Because of occasional significant differences in blood pressure in the two arms,[10] all readings should be made in the same arm, preferably the right arm. Diastolic readings as here reported are recorded at the fourth phase. The entire test occupies less than five minutes and no preparation is necessary.

The findings in the series of 30 cases studied are summarized in table 1, together with the highest and lowest routine readings during hospitalization and the response to the cold pressor and sodium amytal tests.

The average maximum blood pressure levels attained with the breath holding and with the cold pressor tests were similar (breath holding 208/133, cold pressor 211/130) and correspond closely to the highest blood pressure recorded routinely during the period of hospitalization (208/124). Most frequently the admission blood pressure was highest; indeed, the initial blood pressure reading on physical examination may be regarded as a psychic pressor test and has been recognized as having the same significance. In 18 cases the pressor effect of ammonia inhalation and of breath holding was compared (table 2). The rise in diastolic pressure was similar (ammonia 24 mm., apnea 22 mm.) but the increase in systolic pressure was distinctly greater with ammonia inhalation (ammonia 37 mm., apnea 27 mm.). Stimulation of the trigeminal nerve by ammonia inhalation, as Allen[11] has shown experimentally, not only provokes a decided rise in blood pressure but causes involuntary suppression of respiration. The striking pressor effect observed with ammonia inhalation may therefore in part be due to apnea in addition to trigeminal stimulation. In normal persons, as shown by Bing,[12] inhalation of irritants such as acetic acid or ammonia ordinarily raises the blood pressure approximately 10 mm., only exceptionally as much as 20 to 25 mm.

Hyperventilation alone reduced the blood pressure from 187/114 to 171/103. Carotid pressure alone caused a fall from 190/116 to 169/101. The effect of hyperventilation combined with carotid pressure was distinctly greater than with either procedure alone, the blood pressure falling from 187/113 to 157/94. These findings correspond fairly closely to the results obtained with 9 Gm. of sodium amytal, in which the blood pressure fell from 189/114 to 151/97. With hyperventilation plus carotid pressure the average fall in systolic pressure was 30 mm. compared with 38 mm. with sodium amytal. The fall in diastolic pressure was

slightly greater with hyperventilation plus carotid pressure (19 mm.) than with sodium amytal (17 mm.).

The greater fall in systolic pressure obtained with sodium amytal may be attributed in part to a decrease in cardiac output. Blood pressure is influenced not only by vasomotor control of the arterioles but also by systolic cardiac output and the heart rate. While in certain individuals carotid sinus pressure causes a definite sinus bradycardia, this factor did not contribute significantly to the depressor effect in the cases studied. When pressure is exerted on the left rather than on the right carotid sinus, slowing of the heart rate is negligible although the depressor response is equally great. In 2 subjects in whom definite bradycardia developed on carotid sinus pressure, intravenous administration of atropine $\frac{1}{50}$ grain (0.0013 Gm.) prevented slowing of the heart rate but did not inhibit the fall in blood pressure. Mandelstamm and Lifschitz [13] likewise found in an extensive study that the depressor effect of left and right carotid sinus pressure was the same and that administration of atropine prevented slowing of the heart rate but did not influence the fall in blood pressure. Similar observations were made by Galdston and his associates,[14] who noted further that following administration of atropine the fall in arterial pressure on carotid sinus stimulation was in fact often greater than before its injection. The depressor effect of overventilation is not due to the mechanical effect of respiration on the circulation, for no fall in blood pressure occurs if hyperventilation is carried out with air containing carbon dioxide.[3] As shown by Dale and Evans,[15] carbon dioxide is necessary for the normal functioning of the vasoconstrictor center, and the blood pressure changes with apnea and overventilation are to be attributed to the specific effect of carbon dioxide on the vasomotor center.

COMMENT

In a recent review of normal blood pressure and its variations by Allen [16] it was emphasized that "a single measurement of blood pressure, especially in a person who is anxious or emotionally unstable, can have little value. . . . The only way in which to learn all the facts about blood pressure is to make readings at frequent intervals during the day and night, and daily over a period of at least a week." Employment of the procedures suggested in this study, i. e. blood pressure determination during breath holding or inhalation of spirit of ammonia and during hyperventilation plus carotid pressure, makes it possible to obtain information concerning the range of blood pressure in much simpler fashion. These tests may be carried out with little more time or effort than is required to record the blood pressure on routine examination. The breath holding and ammonia blood pressure levels are as high as or higher than the cold pressor "ceiling." Conversely the depressor effect of hyperventilation plus carotid pressure is similar to that of sodium amytal, which has been regarded as the best of the depressor tests.[17]

Pressor, and particularly depressor, tests are of value not only in estimating the status of the hypertensive subject but also in the selection of therapeutic measures. Thus, Allen and Adson [18] find that "the more nearly the blood pressure approaches normal as a result of rest, administration of sodium amytal and the injection of pentothal, and the less marked the vascular disease the more likely extensive sympathectomy is to reduce the blood pressure significantly. . . . When blood pressure is not reduced markedly it is useless to perform extensive sympathectomy for essential hypertension."

The procedures employed to study blood pressure responses, i. e. hyperventilation, pressure above the carotid sinus, administration of barbiturates, spinal anesthesia and observation of blood pressure on prolonged bed rest and during sleep, all operate by decreasing vasomotor tone and give the basal blood pressure relatively free of the influence of the vasomotor center. Conversely, pressor tests such as immersion of the hand in cold water, inhalation of carbon dioxide and breath holding accentuate vasomotor activity by stimulating the vasomotor center. It becomes possible, therefore, employing the breath holding pressor test and the hyperventilation-carotid pressure depressor test to differentiate the vasomotor or neurogenic component in hypertension from the humoral factor, whose maximal effect presumably is indicated by the basal blood pressure free from vasomotor influence.

In renal hypertension the blood pressure is relatively fixed and is but slightly influenced by pressor and depressor procedures, in contrast to essential hypertension.[19] These findings in renal hypertension indicate that the basal blood pressure is set at a high level by the humoral renal pressor mechanism and that the vasomotor or neurogenic component is relatively negligible. It is of interest that in essential hypertension, unlike renal hypertension, the blood pressure falls to a much greater degree with depressor tests. A spontaneous fall in blood pressure to normal occurs very frequently in essential hypertension. Fifty-six per cent of 76 unselected, untreated cases studied by Ayman exhibited this finding.[20]

An average diastolic pressure of 91 was attained with hyperventilation plus carotid pressure in the 35 cases studied. This is but slightly above normal limits. In fully 20 of the total of 35 subjects in whom pressor and depressor responses were investigated, the minimum blood pressure fell to well within the normal range. In these 20 subjects with an average maximal blood pressure of 203/118 the minimum pressure on depressor testing average 122/75. The attainment of normal blood pressure in the majority of cases by inhibition of vasomotor control suggests inescapably that, in the earlier stages of essential hypertension at least, the humoral factor does not play an important role and that the neurogenic or vasomotor component is the more important determinant in the elevation of blood pressure.

Vasomotor control of arteriolar tonus is exerted chiefly in the splanchnic area. The observations of Jansen, Tams and Achelis [21] indicated that the vasoconstriction producing hypertension is confined chiefly to the splanchnic area. This concept, questioned by

some,[22] has been sustained by the more recent studies of Eichna and Wilkins, Abramson and Fierst, Sheard and his associates and Apperly and Cary [23] These investigators have demonstrated an unequal distribution of blood flow in hypertension with augmented circulation to the extremities, signifying splanchnic vasoconstriction. As pointed out by Abramson,[24] these observations weaken the hypothesis that hypertension is due to a humoral vasoconstrictor substance, for under such circumstances generalized arteriolar vasoconstriction would be expected to occur, involving the extremities as well as the remainder of the vascular bed.

Further evidence that vasoconstriction is limited chiefly to the splanchnic area in hypertension is afforded by the distribution of sclerosis in the arterioles. Arteriolosclerosis, which follows prolonged vasoconstriction in hypertension,[25] occurs preponderantly in the abdominal viscera, i. e. the kidney, spleen, pancreas and liver.[26] The terminal arterioles of the other organs, excepting the brain, are rarely involved in the arteriolosclerotic process and then to only an insignificant extent.

The regular findings of arteriolosclerosis in the kidneys of hypertensive subjects at necropsy suggested, after Goldblatt's demonstration that renal ischemia could produce hypertension experimentally,[27] that renal ischemia might also be the basis of human hypertension.

It has been shown by Page and his co-workers [28] and by Braun-Menendez and his associates [29] that the kidney liberates a proteolytic enzyme (renin) into the blood stream which acts on one of the blood globulins (a_2 globulin) to produce a polypeptide with a pressor effect (angiotonin, hypertensin) An increase in circulating renin and angiotonin has been reported in experimental renal ischemia [30] and clinically in eclampsia and severe glomerulonephritis [31] Another pressor mechanism has been demonstrated in the ischemic kidney, i e. the production of pressor amines by decarboxylation of certain aromatic amino acids.[32] In the presence of adequate oxygen such pressor amines are converted to inactive aldehydes by renal amine oxidases

There is no evidence, however, that either the renin or the pressor amine mechanism is the cause of human hypertension. Renin is not found in the blood in essential hypertension [33] (although it is observed in renal hypertension as in severe glomerulonephritis), nor is there an increase of the globulin substrate precursor of angiotonin in essential hypertension.[34] The questionable role of humoral pressor substances in hypertension is suggested further by the failure of extensive transfusions from hypertensive subjects to cause any elevation of blood pressure in the recipients [35]

If essential hypertension were due to a humoral pressor substance one would expect widespread vasoconstriction of the vascular bed. However, the vasoconstrictor in essential hypertension is limited to the vessels under most active vasomotor control, i e the arterioles, and as already mentioned is most striking in the splanchnic bed In nephritic hypertension, in eclampsia and in malignant nephrosclerosis (hypertension with renal insufficiency), as Fishberg [36] remarks, "there is often a high degree of accompanying capillary and venular constriction, so that the patient appears pale," whereas "in the benign phases of essential hypertension there is relatively little accompanying capillary and venular constriction, for which reason the patient may appear ruddy." This distinction provided the basis for Volhard's classification of hypertension into pale and red types,[37] a concept which is supported by the recent demonstration of circulating pressor substances in renal but not in essential hypertension The pressor amines cause generalized vasoconstriction,[38] and while the effects of angiotonin more closely resemble those of human essential hypertension, angiotonin causes vasoconstriction of the pulmonary arterioles, whereas this does not occur in human hypertension [39]

Conclusive evidence that renal ischemia with its attendant pressor effect is not responsible for essential hypertension is afforded by several studies demonstrating that renal blood flow in this condition is normal [39]

This is consistent with pathologic studies based on renal biopsy obtained during sympathectomy in which no evidence of renal arteriolosclerosis was found in the earlier stages of essential hypertension.[40] It is evident, therefore, that arteriolosclerosis of the kidneys and renal ischemia cannot be responsible for the genesis of essential hypertension. The role of the kidney in essential hypertension has been thus summarized by Smith and his collaborators:[41] "So far as the genesis of essential hypertension is concerned, the kidney appears to be the victim rather than the culprit." Page[42] expresses a similar view: "The evidence taken as a whole offers little support for the view that persistent reduction of blood flow and oxygen utilization occurs within the kidneys except when hypertension is of long duration and severe secondary vascular change has supervened."

In later stages of essential hypertension renal arteriolosclerosis occurs constantly, with a decrease in renal blood flow paralleling the severity of the vascular changes in the kidneys.[43] With the development of organic lesions in the renal arterioles and decreased renal blood flow in long standing essential hypertension and in malignant hypertension it is likely that the renal pressor factor may come to play a role in hypertension. That a humoral component is important in the later stages of hypertension and particularly in malignant nephrosclerosis is indicated by the failure of depressor agents acting on the vasomotor center, or sympathectomy, to influence beneficially the elevated blood pressure.[18] Page,[42] employing perfusion of the rabbit's ear, has shown that a protein vasoconstrictor substance similar to angiotonin occurs in human serum after a wide variety of renal injury causing hypertension and is regularly present in the malignant phase of essential hypertension. He suggests that determination of this peripheral vasoconstrictor substance gives an indication that the humoral mechanism has come into action.

Consideration of the renal pressor and depressor mechanisms has been concerned chiefly with their significance in hypertension. While these agents do not appear to play a part in the etiology of hypertension, it is possible that they perform an important physiologic function in the normal individual. The blood pressure influencing agents of the kidney may normally function in maintaining the basal "vital" level of the blood pressure. Superimposed on this, a variable control is exercised by the vasomotor center in response to requirements determined by physiologic and environmental changes. The two components may be distinguished by employing the tests already suggested.

Renin is not a pathologic constituent, for it has repeatedly been demonstrated in extracts of renal tissue since Tigerstedt and Bergmann's original experiments in 1898. This proteolytic enzyme apparently is a normal enzyme of renal tissue, i. e., a cathepsin. Under abnormal metabolic conditions in the kidney which are known to produce hypertension (e. g., ischemia due to arterial or venous obstruction, toxic interference with function as in glomerulonephritis, mechanical interference with function as in urinary tract obstruction, functional overloading as in extensive extirpation of renal tissue), the proteolytic enzyme renin may be passed into the circulation in increased amounts, possibly as the result of altered permeability of the renal cells. That an increased loss of normally present renin, rather than an increased production, occurs is suggested by the finding of increased amounts of renin in the circulation in acute experiments, as in renal ischemia produced by hemorrhage or clamping the renal artery.[30]

Increasing doubt that the kidney plays a primary role in the genesis of hypertension focuses attention on other factors as a cause of the heightened vascular reactivity. Conceivably, the increased pressor response to such agents as carbon dioxide and painful (cold) and irritant (ammonia inhalation) stimuli might be due to a local increased sensitivity of the arterioles themselves to pressor stimuli. Fatherree and Brown[44] have shown, however, that there is no essential difference in the sensitivity of the arterioles of normal and hypertensive subjects to the administration of epinephrine, a substance whose vasoconstrictor activity is exerted directly on the arterioles. As stated by these investigators, their study "supports the idea that in hypertension the abnormality which results in an overactivity of the vasomotor system in response to certain stimuli, such as carbon dioxide and cold, is not the result of any hypersensitivity of the arterioles to pressor stimuli but is probably situated centrally in the vasomotor centers." Heightened local arteriolar reactivity to pressor stimuli may, however, be significant in later stages of hypertension, for the hypertrophy of the muscular media which regularly occurs predisposes to exaggerated constriction in response to pressor stimuli. Hypertrophy of the muscular media, once initiated, may explain the frequent persistence of elevated blood pressure after removal of an atrophic or pyelonephritic kidney, or sympathectomy, and possibly following toxemia of pregnancy.

The findings of the present study and the evidence cited favor a vasomotor, or neurogenic, origin of essential hypertension, a concept that had many proponents before Goldblatt's studies stimulated interest in the renal mechanism. It has been regarded by some[45] that hypertension is due to organic changes in the vasomotor center, i. e. medullary ischemia, but this view is not sustained by adequate factual data. Experimentally hypertension can be produced by procedures which decrease blood flow to the medulla.[46] It has been claimed that arteriosclerotic changes are found regularly in the small vessels of the medulla in hypertension and that excitation of the vasomotor center consequent to ischemia is responsible for hypertension.[47] Other studies,[48] however, have indicated that in the majority of cases of hypertension no evidence of arteriosclerosis of the vessels in the medulla in the region of the vasomotor center is found and that the region of the vasomotor center is morphologically intact. While hypertension in the majority of cases evidently cannot be ascribed to ischemia of the vasomotor center, it is of interest that "patients who had thickened arteries in this part of the brain without an accompanying elevation of blood pressure were *not found*." [48] It appears possible that arteriosclerotic changes in the region of the medulla may contribute to the genesis of hypertension in older age groups and that the exaggerated pressor response to vasomotor stimuli so frequently observed in elderly arteriosclerotic persons [49] may be on this basis.

Another mechanism influencing the vasomotor center has been considered in its possible relation to hypertension. Sustained elevation of the blood pressure can be produced experimentally by section of the moderator nerves from the carotid sinus and aorta.[50] However, there are no significant pathologic or physiologic changes in the carotid sinus in hypertension [51] and there is no evidence that carotid sinus reflexes acting on the vasomotor center play a causative role in hypertension.

The activity of the vasomotor center is influenced not only by such factors as blood flow to the medulla, oxygen and carbon dioxide tension, and carotid sinus reflexes, but also to a great degree by the cerebral cortex. Increasing attention is being paid to the psychosomatic factor in diseases peculiar to civilized man. Environmental influences, as well as heredity, play an undeniably important role in the genesis of essential hypertension. It has been abundantly demonstrated that hypertension is conspicuously rare in primitive races and in sedentary groups removed from urban civilization. Thus, hypertension is rare in African Negroes,[52] but its incidence is two and one-half times greater than in the white race among Negroes in metropolitan areas of the United States.[53] A distinct personality in hypertension was described some time ago by Moschcowitz [54] and more recently has been emphasized by numerous authors.[55] Essential hypertension is regarded as one type of manifestation of a psychoneurotic condition based on chronically excessive, inhibited, hostile (aggressive and competitive) impulses.[55] The sustained vasomotor stimulation resulting from such psychologic tension may ultimately lead to established hypertension. It is of interest that in schizophrenia, in which condition conflicts and frustration do not exist, owing to complete withdrawal from reality, the blood pressure is uniformly low.[56]

SUMMARY

Blood pressure responses were studied in 35 cases of essential hypertension. Comparison was made in 30 cases between the pressor effects of breath holding and immersion of the hand in cold water, and the depressor response to sodium amytal, hyperventilation, pressure above the carotid sinus and combined hyperventilation and carotid sinus pressure. The maximum blood pressure levels attained with the breath holding and with the cold pressor tests were similar (breath holding 208/133, cold pressor 211/130). The depressor effect of hyperventilation or carotid pressure alone was not as great as that following sodium amytal, but when these two procedures were combined the lowest blood pressure level attained (157/94) corresponded quite closely to that resulting from sodium amytal (151/97). In 18 cases, including 13 of the aforementioned 30 cases, the pressor effect of inhalation of aromatic spirit of ammonia was compared with breath holding. The average maximal blood pressure attained with ammonia was 213/128, with breath holding 202/126. The ammonia test is particularly useful in subjects who cannot cooperate well in maintaining apnea sufficiently long to record blood pressure changes.

The variability of the blood pressure in hypertension makes single casual readings misleading. It is therefore preferable to record the blood pressure in terms of its maximum and minimum range. Employment of the breath holding or ammonia inhalation pressor test and the hyperventilation plus carotid pressure depressor test, as suggested, makes it possible to determine the range of the blood pressure with little more time or effort than is required to record the blood pressure routinely. In the 35 cases studied the blood pressure range determined with these procedures was 208/130-153/91.

Application of pressor and depressor tests as described makes it possible to differentiate between the humoral and neurogenic components in hypertension. Variations in carbon dioxide content of the blood induced by breath holding and hyperventilation, as well as carotid sinus pressure and various other pressor and depressor agents, alter the activity of the vasomotor center. The basal blood pressure level attained with depressor tests indicates the blood pressure relatively free of vasomotor influence. This basal level of blood pressure is maintained by humoral mechanisms, e. g. renal pressor (and possibly depressor) agents. The blood pressure influencing agents of the kidney (pressor and depressor) may exercise an important physiologic function in maintaining the basal "vital" level of the blood pressure. Superimposed on this a variable control is exercised by the vasomotor center in response to requirements determined by physiologic and environmental changes. The maximal effect of the neurogenic or vasomotor component is indicated by the blood pressure level attained with pressor tests.

There is no evidence to indicate that the renal pressor mechanism plays a part in the genesis of essential hypertension. The normal level of basal blood pressure observed in the earlier stages of hypertension suggests that in the initial stages of essential hypertension at least the humoral factor does not play an important role and that the neurogenic or vasomotor component is the more important determinant in the elevation of blood pressure. Thus, in 20 of the 35 cases studied, with an average maximal tension of 203/118 the basal blood pressure on depressor testing with inhibition of vasomotor control averaged 122/75.

With the development of organic lesions in the renal arterioles in the later stages of essential hypertension, and concomitant decreased renal blood flow, it is likely that the renal pressor mechanism ultimately comes to play a role in hypertension. That a humoral component does play a role in the later stages of hypertension and particularly in the malignant phase of essential hypertension is suggested by the failure of depressor agents acting on the vasomotor center, or sympathectomy, to decrease the blood pressure significantly. Hypertrophy of the muscular media which regularly occurs in hypertension may be a further factor in accentuating elevation of the blood pressure.

Heightened activity of the vasomotor center in essential hypertension cannot regularly be ascribed to organic changes such as arteriosclerosis of the medullary vessels with ischemia of the vasomotor system. In older age groups, however, this factor appears to be more significant. There is no evidence that abnormal activity of carotid sinus reflexes acting on the vasomotor center is of etiologic significance in hypertension. The activity of the vasomotor center is influenced greatly by the cerebral cortex, and psychosomatic factors appear to play an important role in the genesis of "essential" arterial hypertension.

CONCLUSIONS

The lability of the blood pressure in essential hypertension makes it desirable to record the maximum and minimum range rather than individual readings. This may be accomplished in simple fashion on routine examination by employing breath holding or brief inhalation of spirit of ammonia to attain the maximum pressor level, and by hyperventilation combined with carotid sinus pressure to obtain the basal depressor level. Application of these procedures makes it possible to differentiate humoral and neurogenic (vasomotor) components in hypertension. The basal blood pressure, which is largely determined by the humoral renal pressor mechanism, is normal in the earlier stages of hypertension, indicating that the humoral mechanism does not initiate the elevation of blood pressure in essential hypertension. In later stages, as the result of renal arteriolosclerosis and ischemia, the renal pressor mechanism becomes of greater importance. Hypertrophy of the arteriolar muscular media with an exaggerated response to stimuli may be a further factor in accentuating the elevated blood pressure. The heightened activity of the vasomotor center, which is responsible for the elevation of blood pressure in the earlier stages of essential hypertension, is probably to be attributed in large measure to psychosomatic influences. In older persons degenerative vascular changes in the medulla may be a contributing factor in heightened vasomotor pressor activity and hypertension.

THE TREATMENT OF INFLUENZAL MENINGITIS

MARGARET H. D. SMITH, M.D.
PAUL E. WILSON, Sc.D., M.D.
and
HORACE L. HODES, M.D.
Baltimore

Meningitis due to Hemophilus influenzae is a not uncommon disease of infancy and early childhood. Both sulfonamides and specific rabbit antiserum have been used widely and with considerable success in the treatment of this infection for about five years. It seems appropriate at this time to sum up results obtained with the present treatment in order to facilitate the evaluation of new antibiotic substances when those effective against H. influenzae become generally available for clinical trial.

In 1922 Rivers,[1] in a review of the literature on influenzal meningitis, pointed out that the mortality rate in 200 reported cases was 92 per cent, or, in reality, even higher, since many cases are overlooked or not reported. He furthermore called attention to the fact that 12 of 17 patients who recovered were 2 years of age or older. Wilkes-Weiss and Huntington [2] in 1936 reviewed 500 cases and found a mortality of 97.6 per cent under the age of 2 and 79.5 per cent over the age of 2.

Immune goat serum,[3] bactericidal guinea pig serum [4] and Fothergill's immune horse serum were used in treatment between 1915 and 1939 with only slight effect on the mortality rates. Fothergill [5] in 1937 reported 201 cases treated with horse serum, the death rate being 84.6 per cent; these figures included Silverthorne's series of 36 patients with 11 recoveries and Schwentker's 17 cases with 5 recoveries.

At about the same time, reports began to appear in the literature of isolated cases treated with sulfonamides. Aléman [6] made an exhaustive survey of the literature up to 1940 and was able to collect from the literature and her own clinic in New Orleans reports of 82 cases treated with sulfanilamide, in which there were 10 recoveries. Six of the recovered patients were above 2 years of age.

Both Pittman [7] and Alexander [8] attempted to evaluate by means of mouse protection tests the relative efficacy of sulfanilamide, sulfapyridine and sulfadiazine in combating H. influenzae infection. Both found sulfapyridine superior to sulfanilamide and sulfadiazine most efficacious of all. It is not surprising, then, that recent journals contain reports of recoveries from influenzal meningitis following administration of sulfadiazine or some other sulfonamide alone. Sako, Stewart and Fleet [9] recently reported 23 cases; 13 patients received sulfadiazine only; 2 infants under 6 months of age died, while 11 patients recovered, 1 of them a 4 months

old infant. Four of their patients received both sulfadiazine and horse serum: the 2 infants under the age of 2 months died, whereas the 2 older ones survived.

It seems clear then that the disease tends to be less severe in older children than in young infants, and that any suitable therapeutic agent brings about more recoveries among these older patients.

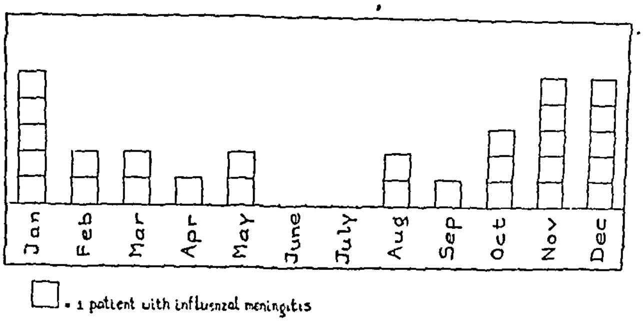

Chart 1.—Seasonal distribution of 28 patients with influenzal meningitis.

Working along lines suggested by Pittman's [10] earlier investigation, Alexander [11] in 1939 successfully prepared a potent rabbit serum against Hemophilus *influenzae* type B. She [12] herself reported the results of treating 50 patients treated with rabbit serum and sulfonamides, the mortality being 17 per cent in patients over the age of 7 months and 75 per cent in the younger age group.

The present series includes all of the proved cases of influenzal meningitis admitted to Sydenham Hospital since January 1941, at which time the Baltimore City Health Department and the Maryland State Department of Health made specific rabbit serum available to all patients regardless of their financial status.

SEASONAL INCIDENCE

The seasonal incidence of our cases (chart 1) corresponds to that originally pointed out by Rivers [1] in 1922, the greatest number occurring in November, December and January rather than in the late winter and early spring months, when other respiratory diseases are most prevalent.

AGE

The age distribution of these 28 patients is shown in chart 2 and corresponds to that pointed out by Fothergill and Wright [13] for influenzal meningitis in 1933 and by Waring and Smith [14] for pneumococcic meningitis in 1944. In this connection Fothergill and Wright studied the bactericidal power of whole defibrinated blood in various age groups and found that "with rare exceptions the blood of children between the ages of 2 months and 3 years has practically no bactericidal power against H. influenzae."

CLINICAL PICTURE AND BACTERIOLOGIC DATA

The clinical picture which the patients presented on admission varied considerably, as shown in the accompanying table. In all of these patients the diagnosis was established by finding H. influenzae in one or more spinal fluid cultures. Some were alert but jittery; others appeared severely ill. None showed a rash, but in 20 of the 28 patients H. influenzae was grown from the blood. In 8 the organism was cultured from the nasopharynx, and about half of the patients had catarrhal otitis media. In 3 a hot, swollen joint was present on admission.

The variability of the clinical course is perhaps best indicated by the two following case reports:

Case 12.—A. G. was a 1 year old boy who, following an upper respiratory infection of four days' duration, developed convulsions and diarrhea, treated unsuccessfully at home with several doses of sulfadiazine. On admission he was restless, with a stiff neck and a temperature of 101.4 F. and seemed only moderately ill. The spinal fluid was cloudy; small gram-negative cocci were seen on smear and thought to be meningococci. The spinal fluid culture was sterile on culture. Sulfadiazine was given in the usual doses over an eight day period and the patient became asymptomatic. However, on the tenth day his temperature rose to between 102 and 103 F. At that time both blood and spinal fluid cultures became positive for H. influenzae type B. Sulfadiazine and rabbit serum were administered and the patient improved promptly. In retrospect it seems that the patient must have had mild influenzal meningitis on admission held in check by the sulfadiazine which he received both at home and after admission. The sulfadiazine being discontinued, he apparently relapsed until treated with serum as well as sulfonamide.

Case 17.—O. N., a boy aged 8 months, became ill quite suddenly on the night before admission with chills, fever, vomiting and later prostration. His temperature was 102.6 F. on arrival at the hospital and he seemed moderately ill. His spinal fluid was cloudy and loaded with H. influenzae organisms. Treated with sulfadiazine and specific rabbit serum as well as transfusion, he had fever spiking to 105 F. during the first week, later to 103 F. His course was very stormy for three weeks, and he had convulsions many times. Followed since discharge by his pediatrician, he has developed in every way normally.

Most noteworthy with regard to the spinal fluid findings are the reduction in spinal fluid sugar (as determined by the five tube method) and the frequency with which organisms were found on the admission smear and identified immediately by quelling with type specific serum. All but 1 of our cases was due to H. influenzae type B. The one exception, case 6, had a strain of H. influenzae in both blood and spinal fluid which could not be typed either in our own laboratory or by Dr. Hattie Alexander.

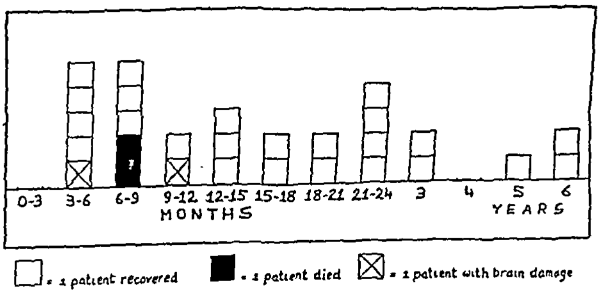

Chart 2.—Age incidence of influenzal meningitis.

THERAPY

Sulfonamides.—All of our patients received, in addition to specific rabbit antibody, one of the sulfonamide drugs in the manner and dosage previously outlined by us for the treatment of other types of meningitis.[15]

We aimed to maintain a blood level of 8 to 12 mg. of sulfadiazine and 3 to 6 mg. of sulfapyrazine per hundred cubic centimeters, i. e. moderate rather than high drug levels. Sulfonamide therapy was continued for about two weeks after apparent clinical cure because of the well known tendency of patients with influenzal meningitis to relapse.

Fifteen of our patients received serum and sulfadiazine alone, with one death; 8 patients received serum and sulfapyrazine alone, and all recovered. The 5 remaining patients received more than one sulfonamide drug at some time during their illness. Obviously no final conclusion can be drawn from this small number of cases with regard to the relative merits of the two drugs. Nevertheless, it seems fair to say that the two are probably about equally effective. There is at least one other report in the pediatric literature of the use of sulfapyrazine in influenzal meningitis: Vandegrift[16] used sulfapyrazine twice in conjunction with immune rabbit serum, and 1 of his patients recovered. Sulfamerazine is also reported to be satisfactory.[17]

* D, sulfadiazine; Pz, sulfapyrazine; Th, sulfathiazole. † At the time of relapse. See case report.
‡ In 2 cases unstandardized serum of low titer was used.

Serum.—Twenty-seven of our 28 patients were treated with anti-H. influenzae type B rabbit serum, the 1 exception being the patient with an untypable strain of organism. In our earlier experience the initial dose of serum was 50 to 75 mg. of antibody nitrogen, but we have gradually come to feel that the initial dose should be relatively large. At present, in a severe case, 125 to 150 mg. is given soon after admission.

The subsequent dosage of rabbit antibody is determined as outlined by Alexander, assaying each day varying dilutions of the patient's own serum against a subculture of the organisms originally recovered from his own spinal fluid. Sufficient serum is administered so that the patient's own serum in a dilution of approximately 1 : 16 will produce capsular swelling of the stock culture. As the patient improves, the organisms die off and cease to produce specific soluble polysaccharide, which combines with the specific antibody. Thus the rate of disappearance of the rabbit antibody slows down and approximates the rate of destruction of any heterologous serum. Conversely it is a good prognostic sign if the patient almost maintains his antibody titer from day to day without further administration of serum.

The total dose of serum has varied in our cases from 75 mg. (the first case treated) to 325 mg., the average being 200 to 250 mg.

Twenty-five of the 27 patients treated with serum received all or most of this serum intravenously. Two patients (24 and 27) received intramuscular serum only with excellent results. This mode of administration, first reported by Boisvert and his associates,[18] should probably be used much more often, as it obviates some of the severe serum reactions observed after intravenous therapy. One patient (1) whose spinal fluid cultures remained positive received intrathecal serum as a last resort, without apparent beneficial effect.

It has been our practice to follow a suggestion originally made by Neter:[19] the patient is given a small desensitizing dose of rabbit serum at least every five days until all need for serum therapy is definitely past.

Lumbar Punctures.—In order to plan properly for the dosage of serum and the duration of sulfonamide therapy, it is essential to follow closely the changes in the spinal fluid. Although a patient with meningococcic meningitis is rarely subjected to more than one lumbar puncture, we feel that patients with influenzal meningitis should be tapped daily until the spinal fluid cultures have been sterile for several days and until the spinal fluid sugar has returned to normal.

[18] Boisvert, Paul L.; Fousek, Mildred D., and Grossman, Marya F.: Intramuscular Administration of Anti-Hemophilus Influenzae, Type B, Rabbit Serum: Report of Its Use in Three Cases of Influenzal Meningitis, J. A. M. A. **124**: 220 (Jan. 22) 1944.

[19] Neter, E.: Observations on Hemophilus Influenzae (Type B) Meningitis of Children, J. Pediat. **20**: 699, 1942.

Mastoidectomy.—Many of our patients showed mild otitis media on admission. In a few instances myringotomy was necessary, but in none of our cases did mastoidectomy appear to be indicated. We feel that the indications of mastoidectomy should be the same whether meningitis is present or not, and that a patient who is suffering from a severe disease such as meningitis should not be subjected to a major operation unless such a measure seems unavoidable.

General Measures.—Intravenous fluids were employed as indicated, and transfusions were given whenever the patient's hemoglobin on admission was below 10 Gm.

COMPLICATIONS OF SERUM THERAPY

The use of the anti-H. influenzae rabbit serum has unfortunately certain unpleasant side effects of minor importance. Perhaps because this serum is less completely purified than certain others in common use, serum reactions are relatively frequent. Our records show that 12 of our 27 patients treated with serum had side reactions. These reactions seem to fall into three types:

(*a*) Immediate anaphylactoid reactions, of which we saw 2 examples. In one 6 months old infant intravenous administration of 125 mg. of rabbit antibody was followed immediately by a severe reaction consisting of fever, cyanosis and asthmatic breathing. The symptoms abated rapidly after administration of epinephrine. The other patient was a 9 months old infant who, to judge by the history, must have had meningitis for a month before admission. After receiving a few cubic centimeters of rabbit serum intravenously he became stiff, cyanotic and apneic. He was finally revived with intracardiac epinephrine. Immediate and severe reactions to serum when administered to very ill patients have been seen by us and described by others[20] as occurring in conjunction with the administration of serum to patients with pneumonia. Their cause is unknown.

(*b*) An interesting type of delayed reaction occurred in 4 of our patients. Routine tests for sensitivity to rabbit serum are given our patients by dropping into one eye a small amount of the material diluted 1:10. Several showed on the following day edema and slight reddening of the soft tissues about the eye which persisted for another two to three days. The conjunctiva was slightly inflamed at the same time.

(*c*) The commonest type of serum reaction was serum sickness, which appeared between the ninth and twenty-third hospital days and was characterized clinically by an urticarial rash in all cases and in most by fever and painful joints in addition. One patient showed fever at the end of the second week in the hospital which could not be accounted for on the basis of the clinical findings and which may have represented abortive serum sickness.

We wish to stress the frequency with which we encountered serum reactions, not because they militate against the use of the serum but because they enforce care in its administration and frequently provide the explanation for fever, malaise and rash occurring late in the course of the disease when the patient was thought to have recovered. Also these reactions in many cases prolong convalescence.

RESULTS

Twenty-four of the 28 patients apparently recovered completely, without sequelae. Seven of these were aged 8 months or less. The following 5 were thought at the time of discharge to show evidence of brain damage:

Patient 2 went home with questionable hydrocephalus but on subsequent follow-up was found to be entirely well.

Patient 8 had some spasticity of one arm.

Patient 11 appeared a complete idiot both on discharge and when seen a year later.

Patient 1 was suffering from severe hydrocephalus.

Patient 18 had mild spastic hemiplegia.

Two of the 28 patients died, a mortality of 7 per cent. One of these, a 9 months old infant, has already been mentioned as having had an anaphylactic reaction on administration of serum. His illness had been of long duration before he came to us and his outlook appeared hopeless from the first. The other patient who died was likewise 9 months of age. There was a delay of two days in her case in starting specific therapy, since the diagnosis was made only on the basis of a positive spinal fluid culture. Moreover, the serum was not given at the beginning in our usual high dosage but rather in smaller divided doses over a period of ten days. At any rate, whatever the reasons, the patient succumbed on the twenty-ninth hospital day.

Instead of speaking of the percentage of deaths following influenzal meningitis, it is probably actually more accurate to group on the one hand those patients who were discharged in satisfactory condition and, on the other, those who died or who were severely crippled. On this basis, we can say that 24 (85 per cent) of our patients did well and that 4 (15 per cent) did not respond satisfactorily: either they died or showed evidence of severe and presumably permanent damage to the central nervous system.

COMMENT

From the bacteriologic point of view patient 6 is of some interest in that the organism recovered from his spinal fluid did not fall into any of the established types of H. influenzae; nor was it found to give with the standard types of antipneumococcus rabbit serum any of the cross reactions which have been described from time to time in connection with strains of H. influenzae.[21] Although most cases of H. influenzae meningitis are due to type B, other types have occasionally been recovered from the spinal fluid.[22] In general, meningitis due to type B is more severe than that due to other types.[23]

The relatively high recovery rate among our very young patients is, we think, dependent on at least two factors. In the first place all of the patients admitted to this hospital are carried immediately into an admission room, where the necessary diagnostic and therapeutic procedures are carried out as expeditiously as possible. Unnecessary manipulation and loss of time in instituting treatment have a deleterious effect on any severely ill person. In the second place the patients seem to do better when given larger doses of serum early in the illness. In this way the patient is certain to have in his blood at all times an excess of antibody. Moreover, it is theoretically possible in this way to increase the amount of antibody supplied to the spinal fluid without the risk of producing block due to the serum itself, a risk which is not negligible when animal serum as such is introduced into the subarachnoid space. That the antibody titer of the spinal fluid is proportional to that of the blood in a ratio of approximately 1:300 has been shown by Freund[24] following both active and passive immunization of rabbits against typhoid. Ramon and Descombey[25] demonstrated a similar relationship with regard to antitoxin in serum and spinal fluid, and Morgan and her associates[26] described the same ratio following active immunization with the viruses of both eastern and western equine encephalomyelitis. That antibody is present in the spinal fluid following intravenous administration of anti-influenzal rabbit serum has been shown by Alexander,[8] although the exact ratio has not to our knowledge been determined.

[23] Alexander, Hattie E: Personal communication to the authors.

Our experience sheds no light on the much discussed question of using intrathecal serum in the treatment of patients who do not respond to the use of intravenous or intramuscular serum combined with sulfonamides. Most of our patients are seen and treated early in the course of the disease, and, owing either to chance or to the use of large doses of serum, seem to recover without intrathecal serum.

In summary, then, we find on the basis of 28 consecutive cases that the intensive use of sulfonamide and specific serum therapy in influenzal meningitis has reduced the mortality until it is comparable to that of meningococcic meningitis. The high cost of the serum, the tedious and repeated determinations of the patient's serum titer and the high incidence of serum reactions lead us to hope that new antibiotic substances will soon "streamline" the treatment.

SUMMARY

1. Twenty-eight consecutive cases of influenzal meningitis have been treated at this hospital since 1941.
2. The seasonal incidence seems to be highest in late autumn and early winter.
3. The age incidence of influenzal meningitis in infancy follows a curve roughly similar to that of pneumococcic meningitis, i. e. the maximum number of cases occur between the ages of 3 and 9 months.
4. Early diagnosis and intensive early therapy, using both sulfonamides and type specific rabbit antibody, have reduced the mortality to a figure comparable to that of meningococcic meningitis. Failure to use serum early in the course of treatment entails unnecessary risk to the patient's life.
5. The mortality has been most strikingly lowered in the younger infants, among whom the mortality is highest.
6. Sulfapyrazine and its sodium salt have been found to be effective in the treatment of this disease.
7. The incidence of serum reactions is high but does not militate against the use of serum.

CENTRAL NERVOUS SYSTEM COMPLICATIONS ASSOCIATED WITH KERNICTERUS

HERMAN YANNET, M.D.
and
ROSE LIEBERMAN, M.A.
Southbury, Conn.

Kernicterus as a pathologic finding has been observed almost exclusively in children that have exhibited the clinical picture of erythroblastosis fetalis. It is therefore a reasonable conclusion that this type of cerebral abnormality in the vast majority of cases is the result of maternal isoimmunization during pregnancy primarily by the Rh factor.

While the neonatal mortality rate in children with kernicterus is very high, a certain number do survive for a variable period. The recognition of these cases in the past has depended on the history of severe neonatal jaundice and the subsequent development of symptoms of central nervous system disease. Most of the reported cases of this type presented a clinical picture in which evidence of basal ganglion injury predominated, such as choreoathetosis and extrapyramidal spasticity.[1] The widespread nature of neuronal damage in kernicterus[2] suggests the possibility that certain of the surviving patients might present other types of neurologic defects. Kernicterus has been demonstrated in infants, moreover, in whom neonatal jaundice or other signs of erythroblastosis fetalis were relatively inconspicuous.[3] Since neither the clinical picture nor the neonatal history need be absolutely characteristic, it seems clear that a further evaluation of the syndrome is indicated.

Mental deficiency is the most common manifestation of extensive cerebral abnormality of prenatal origin. It would appear likely that among large groups of congenitally severely retarded children one might expect to find a small number in whom the cerebral defect was the result of maternal Rh isoimmunization.

That this might be the case was suggested by a preliminary study[4] in which it was found that the incidence of mother-child Rh incompatibility was significantly greater among a group of undifferentiated defectives as compared to a control group consisting primarily of mongolians, spastic diplegias and postinfectious and post-traumatic types.

Our purpose in this paper is to present the results of a much wider study of this kind and to describe briefly some of the clinical conditions encountered that might represent this type of cerebral damage.

MATERIAL AND METHODS

There were in the institution at the time of this study approximately 350 children with intelligence quotients of less than 30. Of the mothers of these children it was possible to obtain at least one blood sample on 277. Of the remainder, a small number were deceased, many failed to respond to one or more written requests to visit

the laboratory, and some could not be located. Studies of the children's blood were carried out only on those whose mothers proved to be Rh negative.

Of the 277 children it was possible to place 158 into well recognized diagnostic classifications, including 45 mongolians, 33 with infantile spastic diplegia and 36 with acquired defects due to cerebral infections or trauma. Also included were cases of phenylpyruvic amentia, craniofacial anomalies, tuberous sclerosis, cerebral lipoidoses and other conditions. These were treated as the control group. The remaining 119 children diagnosed as undifferentiated made up the group in whom the incidence of mother-child Rh incompatibility was being investigated. Before being diagnosed as undifferentiated, every clinical and laboratory facility was employed to rule out known etiologic categories. However, it is appreciated that included in the group are an undetermined number of cases based on recessive genetic factors which could not be diagnosed because of small sibships or lack of adequate family histories. Also included are probably cases of birth trauma without characteristic history or examination, as well as fetal injuries due to maternal illnesses of which no record was available. Prenatal, neonatal or infantile encephalitic processes may also have been inadvertently included. It is therefore clear that if the Rh factor was of etiologic importance in explaining some of the cases in the undifferentiated group, the expected proportion would be relatively small, although significantly greater than one would expect to find in a control group.

Results of Blood Examination

	Total Number	Mother Rh —	Mother Rh — Child Rh +
Control	158	22 (14.0%)	12 (7.6%)
Undifferentiated	119	26 (22.0%)	19 (16.0%)

The anti-Rh serum used was obtained through the courtesy of Dr. Diamond from the Blood Grouping Laboratory in Boston. The method used for typing was that described by Levine.[5] Maternal Rh antibodies were also determined whenever possible, including the so-called "blocking" antibodies, as described by Wiener.[6]

RESULTS

The results are summarized in the table. Approximately 14 per cent of the mothers in the control group were Rh negative. This agrees with the ratio to be expected on the basis of random selection. The random distribution of the Rh factor is such that an Rh negative woman has a 60 per cent chance of giving birth to an Rh positive child.[7] On this basis the 22 Rh negative mothers in the control group might be expected to have 13 Rh positive children, giving 8.2 per cent as the theoretical or random ratio of mother-child Rh incompatibility. This agrees with the actual finding, as the table indicates, of 12 cases (7.6 per cent) of Rh incompatibility in the control group. In the undifferentiated group, on the other hand, 26, or 22 per cent of the mothers, were found to be Rh negative. Moreover, whereas one might have expected to find 15 or 16 Rh positive children in this group, actually 19 were found, giving a ratio for mother-child Rh incompatibility of 16 per cent in the undifferentiated group as compared to 7.6 per cent in the control group. The difference between these ratios is statistically significant.

On the basis of the findings in the control group as well as on theoretical considerations, only 9 cases of mother-child Rh incompatibility should have been found in the 119 cases in the undifferentiated group; actually 19 were encountered. It would therefore seem reasonable to expect that of the 19 cases approximately 10 may represent examples of cerebral damage due to maternal Rh isoimmunization.

The identification of those cases which definitely represent examples of fetal injury due to maternal Rh isoimmunization presents a problem which cannot be entirely solved as yet. A clinical appraisal of the 19 cases in which isoimmunization was possible on the basis of blood incompatibilty yields three fairly distinct groups. These are now summarized:

Group 1.—This group includes 3 cases in which there is definite evidence of maternal isoimmunization. In cases 1 and 2 high titers of Rh antibodies were found in the mothers five and three years after delivery respectively, while in case 3 the mother died in 1942 following a transfusion of Rh positive blood administered soon after the delivery of a child who died with typical erythroblastosis fetalis. A brief clinical description of these cases follows:

Case 1.—W. V., a boy, was born Dec. 9, 1939, the result of the second pregnancy, which was entirely uneventful. The preceding pregnancy in 1938 terminated at 7 months with the delivery of a dead fetus. A report from the hospital gave the cause of death as "intrauterine asphyxia" with little qualifying details. The mother at this time was given a transfusion because of postpartum bleeding, the husband, who was Rh positive, acting as donor. No reaction to this transfusion was recorded. The patient was delivered without difficulty after a four hour labor. On the third day he developed jaundice and fever, and blood studies were reported by the hospital as being characteristic of erythroblastosis fetalis. Peculiar spasms, first noted at the end of the first month, became gradually more frequent, so that by the third month there was generalized spasmodic increase in muscle tone. Abnormal, athetoid-like movements of the extremities appeared one month later and persisted. Periods of opisthotonos also became evident. There was no sign of any significant mental development. He was admitted to the Southbury Training School on Dec. 28, 1944 at 5 years of age. Examination revealed a decidedly emaciated child whose mental age was estimated at 5 months. The head measured 47.5 cm. in circumference and there was a moderate degree of athetosis of the extremities, most pronounced in the left arm, and some facial grimacing. Although muscle tone was usually increased, there were short periods of relaxation during which hypermobility was quite striking at the hips, knees, ankles and wrists. Deep tendon reflexes could be obtained only with difficulty. There was no ankle clonus, but the Babinski responses were bilaterally extensor. Tonic neck reflexes could frequently be elicited. Laboratory findings were consistently within normal limits. The remainder of the examination was not contributory. The child was admitted to our hospital on four occasions in the following five months with upper respiratory infections, during which no peculiarity was noted in the temperature course. There has been no significant change in the clinical picture since admission.

Case 2.—M. J. Mc., a boy, was born Sept. 19, 1941, the product of the second pregnancy. An older sibling born in 1940 is Rh positive, had a normal neonatal period and was found to be entirely normal in 1944. There was a third pregnancy in 1943, resulting in an Rh positive infant who survived a stormy neonatal period during which a characteristic picture of erythroblastosis fetalis was present, requiring frequent transfusions. The latter child was found to be entirely normal at 14 months of age. The patient was born after an uneventful pregnancy and uncomplicated, short labor. Jaundice appeared on the second day and became intense during the following days. Head retraction and generalized short muscle spasms appeared on the third day and persisted to a more or less noticeable degree, especially when disturbed. No transfusions were required and the child was discharged on the tenth day, with the jaundice practically gone. Abnormal movements of the extremities were first noted at the fourth month. No significant mental development was evident. Feeding was always difficult and associated with much coughing and gagging.

The child was seen frequently by physicians because of hyperpyrexia, occasionally associated with signs of respiratory infection but frequently without evident cause. He was admitted to the Southbury Training School on Oct. 19, 1944 at the age of 3 years. Examination at this time indicated that the boy was extremely malnourished with a mental age estimated at 3 months. The head was symmetrical and measured 50 cm. in circumference. The only significant findings were in the central nervous system. There was athetosis of the extremities, more pronounced on the left side. The head was held rotated to the right, and there was constant facial grimacing. The muscle tone was increased irregularly in all extremities most of the time. This child, as in case 1, also exhibited, during periods of relaxation, accentuated hypermobility at the knee, ankle and wrist joints. The deep tendon reflexes could not be obtained, and the Babinski responses were equivocal. Studies of the blood, urine and spinal fluid were within normal limits. The course was characterized by episodes of unexplained fever frequently over 104 F. Blood cultures on three occasions during these periods were sterile. On Feb. 2, 1945, about four months after admission, the child died exhibiting hyperpyrexia without significant clinical signs of infection. At autopsy a small quantity of thick pus was found in the right mastoid cells, although otoscopy shortly before death showed no significant abnormalities in the canals or tympanic membranes. The lungs showed a focal lipoid pneumonia. The brain and spinal cord was examined by Dr. S. H. Durlacher of the pathology department of the Yale University School of Medicine. The findings were essentially similar to those previously reported by Zimmerman and Yannet[1] both in distribution and in the nature of the changes, so that a detailed description is not included. Briefly, widespread but patchy demyelinization and loss of ganglion cells characterized the findings. This was especially prominent in the basal ganglions.

Case 3.—T. W., a boy, was the result of the third of five pregnancies. The first two children, born in 1934 and 1935 respectively, had normal neonatal histories and showed subsequent normal and uneventful development. The fourth pregnancy, in 1940, terminated in the delivery of a stillborn child. The fifth pregnancy, in 1942, also resulted in a stillborn child. During this postpartum period, because of a hemorrhage, the mother was transfused, a professional donor being employed. A severe reaction ensued, resulting in the death of the mother. Subsequent study showed that the mother's blood was Rh negative and the donor's Rh positive.

The patient was delivered without difficulty on Oct. 2, 1938 and appeared normal at birth. Within twelve hours he developed a rapidly increasing jaundice and severe anemia. A diagnosis of erythroblastosis fetalis was made, and the child was transfused repeatedly. He made a gradual recovery and seemed in good condition when discharged three weeks later. It soon became apparent that his development was significantly retarded. He failed to sit alone before the second year and began to walk during the third year. He made no effort to talk. There was no history of abnormal motor activity or convulsions. He was admitted to the Southbury Training School on March 16, 1943 at 4½ years of age. At this time he was well nourished and had a mental age of 2 years. He made no effort to talk but could understand and carry out simple commands. The head was symmetrical and measured 50 cm in circumference. The significant findings were confined to the examination of the central nervous system. The gait was grossly ataxic, with internal rotation of the feet. There was a well established lumbar lordosis. Definite genu recurvatum was present bilaterally, more pronounced on the right. There was an alternating strabismus with normal fundi. A generalized hypotonia could be demonstrated, which was symmetrical in distribution. There was well defined ataxia of both upper extremities and the trunk. No abnormality in exteroceptive sensation was present. The deep tendon reflexes were easily obtained and equal. The Babinski responses were flexor, and the abdominal reflexes were present. The course in the institution was characterized by a slow but definite improvement in motor activity. The gait improved considerably, so that locomotion became relatively adequate, although ataxic. His speech has shown favorable progress, although still greatly retarded. The hypotonia and associated muscle weakness is still evident but less definite. His mental age is estimated, at this time (June 1945) at 3 years, giving the boy an intelligence quotient of about 45.

Group 2.—The next 3 cases are grouped together because, although the evidence for maternal Rh isoimmunization was presumptive, it was not as definite as in the preceding group. In cases 4 and 5 no Rh antibodies could be demonstrated in the mothers, while in case 6 serum could not be obtained for study. Also patients 4 and 5 were born at home, and because they were relatively older (19 and 20 years respectively) the neonatal histories, as obtained from the mothers, were not considered accurate or adequately detailed. However, as the following brief summaries will indicate, it was likely that all of these children had erythroblastosis fetalis.

Case 4.—N. J., a boy, was one of twins, born without difficulty at the end of the fifth pregnancy, which was uneventful. The other twin, a girl, was said to have been entirely normal in development. Unfortunately she could not be reached for blood examination. The preceding 4 children, born in 1914, 1917, 1923 and 1925 respectively, were said to be normal but were also unavailable for study. A sixth pregnancy, in 1934, ended in a miscarriage at 5 months, and the seventh pregnancy resulted in a full term stillborn fetus.

The patient was born Dec. 19, 1926 at home, attended by a midwife. He seemed normal at birth. On the third day he was noticed to be jaundiced and very pale. The following day he had a generalized convulsion, followed by numerous cyanotic spells. He did poorly during the following two months, gaining little weight. At about 4 months of age, abnormal movements of the extremities became apparent and persisted. His development was greatly delayed. He could not support his head until 2 years of age; he sat alone at 3 years and walked at 9 years. Speech was never intelligible. He was admitted to the Southbury Training School on Nov. 2, 1944 at 18 years of age. Examination at this time revealed that he was moderately well nourished and that his mental age was estimated at about 3 years. His head was symmetrical and measured 50 cm. in circumference. There was generalized athetosis, with facial grimacing. The head was held rotated to the right. The gait was suggestively ataxic, and there was evidence of incoordination in the use of his arms. There was sustained increase in muscle tone with no definite periods of relaxation, as was exhibited in cases 1 and 2. The deep reflexes were equal and of normal intensity. The Babinski responses were flexor; the abdominal reflexes were obtained with difficulty, and ankle clonus was absent. The remainder of the examination was not significant. Laboratory findings were not abnormal. The boy's course has been relatively uneventful since admission, and his condition at present is unchanged.

Case 5.—T. S., a girl aged 19 years, was the result of the first pregnancy, which was uneventful. A second pregnancy, in 1938, resulted in a normal child who was found to be Rh negative. The patient was born at home, attended by a physician after an uncomplicated delivery. During the first week there were many attacks of cyanosis. Jaundice appeared early and became intense during the first week, lasting for almost four weeks. The stools were of normal color. Around the fourth month, abnormal movements appeared and persisted. At 7 months of age she had generalized convulsions, which were repeated infrequently during the next year but have not recurred since. Development was greatly retarded. She began to walk alone at 7 years. Speech is still almost unintelligible. She was admitted to the Southbury Training School on Jan. 27, 1944. Examination at this time showed that she was well nourished, and her mental age was estimated at about 5 years. The head was symmetrical, measured 54 cm. in circumference and was held turned to the right. Generalized athetosis was prominent and the gait suggestively ataxic. There was spasmodic increase in muscle tone, but, during periods of relaxation, definite hypotonia was present with hypermobility at the wrists, knees and ankles. Deep reflexes were difficult to elicit, the Babinski responses were equivocal, abdominal reflexes were present and ankle clonus was absent. The remainder of the examination was not remarkable. Laboratory studies were noncontributory. The girl made a good adjustment to her institutional experience, and her present status is essentially unchanged.

Case 6.—C. S., a girl aged 7 years, was the result of a full term, uneventful second pregnancy. The first child was stillborn after a long labor said to have lasted for five days. The cause of death was given as "birth trauma." The patient was delivered without difficulty in a hospital and seemed normal at birth. On the third day jaundice was noted. This became intense rapidly and was said to have persisted for over four weeks. On the third day she developed spasmodic episodes with head retraction. These occurred frequently but gradually subsided by the end of the third week. Around the fourth month increased muscle tone became evident, increasing in severity and persisting. The girl never walked or talked and has been confined to bed. At 6 years of age she began to have generalized convulsions, which recurred at infrequent intervals. She was admitted to the Southbury Training School on June 6, 1943. At this time she was poorly nourished, and her mental age was less than 6 months. The head was symmetrical and measured 49 cm. in circumference. There was no evidence of abnormal movements. There was a generalized but irregular increase in muscle tone that was constant and could be overcome only with considerable force. Fingers were held hyperextended at the metacarpophalangeal joints and flexed at the terminal phalangeal joints. The deep reflexes were hyperactive but equal; there were bilateral ankle clonus and bilateral extensor Babinski responses. The abdominal reflex was absent on the right but present on the left. The fundi were negative. There was gross incoordination of the extraocular movements, and light perception was present. Except for the emaciation and underdevelopment, the remainder of the examination and the laboratory studies were not remarkable. The child remained at the institution for about three weeks and was taken home against advice. There had been no significant change.

Group 3.—The remaining 13 cases are grouped together because of the absence of any significant findings in the histories that would in any way suggest the possibility of isoimmunization in the mothers. Unfortunately, the relatively advanced ages of the patients (average age 24 years) and the fact that the majority were born at home made the neonatal histories, as obtained from the mothers, difficult to evaluate. In about half the cases it was possible to obtain specimens of serum from the mothers for study, but no evidence of Rh antibodies could be demonstrated. Unfortunately the more sensitive slide agglutination method for demonstrating Rh antibodies recently described by Diamond and Abelson[8] was not available. However, on the basis of the incidence of mother-child Rh incompatibility found in our control group it is not unlikely that a few of these do represent instances of cerebral damage on the basis of Rh isoimmunization. However, the clinical picture was in no way characteristic. Eleven were males, and five were first born. There were 4 children who were premature. In 2 of these there was a family history of prior stillbirths. In 1 case a preceding pregnancy had terminated in the delivery of an infant that died at 4 days of age with jaundice, but the data were too meager to warrant a diagnosis. The physical findings were characterized by the absence of signs of specific central nervous system abnormalities except for the severe mental defect. In brief, although there is reasonably good evidence that some of these cases do fall into the group of brain injuries due to Rh isoimmunization, a positive or even a presumptive diagnosis in any individual case was impossible at this late date. The consderation of this possibility seems indicated in every case of mother-child Rh incompatibility, so that evidence of isoimmunization in the mother and the less dramatic signs of erythroblastosis fetalis in the child can be sought for relatively soon after birth. Only in this way will it be possible to be sure that some of the cases that are included in group 3 actually represent atypical examples of kernicterus.

COMMENT

Most of the cases in groups 1 and 2 in which a definite or presumptive diagnosis of maternal Rh isoimmunization could be made show essentially the same clinical picture previously described of surviving patients with kernicterus.[9] This included a stormy neonatal period (now recognized clinically as erythroblastosis fetalis), the early appearance of increased muscle tone followed soon after by abnormal movements of the extremities and relatively severe mental defect. The clinical picture in case 3, however, was strikingly different. The neurologic defect was almost entirely confined to cerebellar dysfunction, while the mental defect, although obvious, was distinctly less than in the other cases. Suggestive evidences of possible cerebellar dysfunction also could be demonstrated in cases 1, 2, 4 and 5, although the signs were overshadowed by the other manifestations of central nervous system injury, of which those referable to the basal ganglions predominated. The presence of signs of cerebellar involvement is not surprising in view of the well defined changes that have been demonstrated in the dentate nucleus in a previously reported postmortem study of this condition.[1]

While the evidence is highly suggestive that a certain number of the cases in group 3 represent bona fide examples of cerebral injury due to maternal Rh isoimmunization, it is nevertheless based almost entirely on statistical considerations. It is apparent that further confirmatory evidence is necessary in this respect. A recent report by Snyder, Schonfeld and Offerman[10] is of interest. These investigators carried out a somewhat similar study of the mothers of 68 institutionalized undifferentiated mental defectives and found almost twice the number of Rh negative mothers and incompatible mother-child relationships than should have been present on the basis of random selection. However, as was stated earlier, definite proof of isoimmunization in the mother and of manifestations of erythroblastosis fetalis in the child should be sought for in every case of Rh incompatibility no matter how benign the neonatal period, and this correlated with the subsequent development of the child. It will be primarily through this type of follow-up that validity will be given to what must remain at present a reasonable possibility at best.

It should be noted that our present studies, for reasons previously stated, have been confined to children in the low imbecile and idiot categories. That lesser degrees of cerebral injury associated with only slight evidence of mental defect and neurologic abnormalities may also result from this sensitization mechanism remains to be evaluated. It is evident that the obstetrician and pediatrician must be alert to the possibilities of this type of fetal injury so that pertinent observations may be made at the most opportune time.

[10] Snyder, L. H.; Schonfeld, M. D., and Offerman, E. M.: The Rh Factor and Feeblemindedness, J. Hered. 36:9 (Jan.) 1945.

The pathogenesis of the central nervous system injury resulting from maternal isoimmunization is at present unknown. On the basis of our present knowledge, the following tentative hypotheses may be postulated. It has been demonstrated by Boorman and Dodd [11] that in Rh positive individuals the Rh factor is present in practically all tissues, although in small amounts, when compared to the agglutinogens A and B. The possibility of irreversible cellular injury due to an antibody antigen reaction has been suggested. The sparing of certain fetuses might be partly dependent on the relative concentration of antigen in the brain. While other tissues also would be involved, their greater reparative capacities than exists in the neuron would militate against permanent injury. The second and more likely possibility would make the cerebral injury entirely secondary to the destruction of the red blood cells during certain periods of fetal life. Thus, only when the ratio of blood destruction to blood formation in the fetus was such as to result in an inadequate supply of oxygen to the developing neuron would permanent injury ensue. This would presuppose red cell destruction at a period in fetal life when the future definitive hematopoietic organ (bone marrow) was inadequate to compensate for the continuing destruction. Later, when this compensation becomes adequate, further neuronal damage would be prevented, although not before a variable degree of injury had already been established. Thus, only in those cases in which maternal antibodies were produced in sufficient concentration relatively early in pregnancy would kernicterus be observed. This concept would agree with the lack of correlation between the severity of the postnatal hemolytic anemia and the occurrence of kernicterus. Finally, the possibility that the products of extensive red cell destruction per se may be injurious to the developing neuron must be considered.

It is to be expected that more patients with kernicterus will survive than heretofore as our knowledge of the treatment of the natal hemolytic anemia expands. The use of Rh negative blood, the appreciation of the relatively large quantity of blood required and the possibility of using separated red cells will function in this direction. Unfortunately, the brain damage cannot be affected by these means. Since concentration of maternal antibodies can be estimated with reasonable accuracy, it is customary, when laboratory facilities are available, to follow the level of maternal antibody formation throughout pregnancy so that premature interruption of pregnancy can be instituted, if the antibody level shows a tendency to rise rapidly. Whether this will result in a reduced incidence of kernicterus is questionable. It is clear that the fetus is exposed to the maternal agglutinins early in pregnancy and that the brain damage is probably well established at a variable period before term. However, reported experience with premature interruption of pregnancy as a prophylactic measure in this respect is too scanty to warrant drawing definite conclusions.

SUMMARY

The incidence of incompatible mother-child Rh blood typings was found to be significantly higher in a group of undifferentiated mental defectives than in a control group. This suggests that the cerebral abnormality of some of these undifferentiated defectives is probably related to maternal Rh isoimmunization during pregnancy.

Of the 19 cases in the undifferentiated group in which this etiologic possibility exists, 6 cases were found in which either definite or presumptive evidence of maternal isoimmunization was present. The neonatal history in all 6 of these cases was considered compatible with the diagnosis of erythroblastosis fetalis. In 4 of these children the clinical picture was fairly uniform, including spasmodic increases in muscle tone, choreoathetosis and evidence of cerebellar dysfunction. In 1 case the signs of cerebellar dysfunction dominated the picture. In the remaining case there was no athetosis, while the increased muscle tone or spasticity was constant rather than spasmodic.

In the remaining 13 cases no definite evidence of maternal Rh isoimmunization could be demonstrated, and the clinical picture was nondescript except for the mental defect. While statistical considerations suggest that probably 3 or 4 of these may also be etiologically related to the Rh sensitization mechanism, it was felt that confirmatory evidence, both clinical and serologic, obtainable during the neonatal period and related to the subsequent failure in mental development, would be necessary before definite conclusions could be reached in this respect.

ABSTRACT OF DISCUSSION

Dr. Stanley Cobb, Boston: This is a good piece of work along an important and new line of investigation. The results suggest that there is much more work to be done in this field, but these results in themselves are not specific enough to be of much value for clinical diagnosis at the present time. They do open up a vista of possibilities for the prevention of cerebral disease in children with its resultant mental defect and other neurologic aftermaths. Previously this had been a field in which therapy was not known and the outlook was hopeless. Now we may at least try to prevent these things by looking for the Rh factor in the blood of the mother and the child. It would be interesting to extend this investigation to cases of Wilson's disease, for here we have a group of patients with both cerebral and hepatic lesions and it might be that the Rh factor would be important in this disease also. The relation of the liver to the basal ganglions has long been a subject of interest to neurologists, and although the jaundice in these patients described by Yannet and Lieberman was in all probability due to destruction of red cells, yet the liver may also be implicated. In the last war there were some cases in which phosgene gas caused acute atrophy of the liver with kernicterus. It is possible that this approach might be used experimentally and illuminate the subject.

Dr. Bronson Crothers, Boston: Dr. Yannet and Miss Lieberman have brought under review a series of cases which can be definitely removed from the discouraging mass of feebleminded individuals for careful study. The clinical picture which results from severe erythroblastosis with cerebral damage is reasonably typical. The children that I have recognized are essentially decerebrate with tonic neck reactions and rigidity with athetosis. They are profoundly defective. The suggestion that there must be many less severe cases should be pursued. The authors make out a case which should be considered by every one who sees young defective children in considerable numbers. It is entirely practicable to collect evidence, and unfortunately the material is readily and continuously available.

[11] Boorman, Kathleen E., and Dodd, Barbara E.: Group Specific Substances A, B, M, N, Rh: Their Occurrence in Tissues and Body Fluids, J. Path. & Bact. 55:329 (July) 1943.

Dr. Herman Yannet, Southbury, Conn.: I am indebted to Dr. Cobb and Dr. Crothers for their discussion and suggestions. The possibility raised by Dr. Cobb that there might be a relationship between kernicterus and Wilson's disease was discussed in an earlier paper (Zimmerman, H. M., and Yannet, Herman: Kernicterus, *Am. J. Dis. Child.* **45**:740, 1933). The striking dissimilarities, especially the times of onset of clinical symptoms in Wilson's disease, make it very unlikely that the two conditions are related. However, Rh investigative procedures could very easily be applied, so that any doubt may be dispelled.

PENICILLIN IN SPINAL FLUID AFTER INTRAVENOUS ADMINISTRATION

Demonstrable penicillin levels in the cerebrospinal fluid have been reported after intravenous or intramuscular administration only in patients who had inflammatory processes of the meninges[1] or when the penicillin was given by direct instillation.[2] Attainment of significant[3] penicillin activity in the cerebrospinal fluid of patients who did not show evidence of meningeal involvement is not reported in the available literature.

McDermott and Nelson[4] and Mackie,[5] utilizing intramuscular doses as high as 500,000 Oxford units, failed to achieve significant cerebrospinal fluid concentration. Our own efforts, during the past twenty-two months, after intramuscular doses of 20,000, 40,000 and 200,000 units have likewise been unsuccessful. Neymann, Heilbrunn and Youmans[6] recently concluded that the intravenous and intramuscular methods of administration of penicillin were ineffective because "the hematoencephalic barrier cannot be breached."

We are presenting a series of cases in which significant levels of penicillin were obtained in the cerebrospinal fluid by means of the intravenous route of administration.

Massive dose penicillin therapy by continuous intravenous drip is being investigated as a method of treatment of early syphilis the results of which will be the subject of a later report. A group of 162 patients exhibiting clinical evidence of primary or secondary syphilis was the subject of this study. All were dark field positive for Treponema pallidum. Eligibility for treatment was determined on the basis of freedom from detectable pathologic changes of the cardiovascular pulmonary, urinary and hemopoietic systems. Electrocardiograms and 2 meter chest roentgenograms were included in the pretreatment medical survey. Cerebrospinal fluid examinations performed routinely before treatment revealed normal findings in all but 9 patients. There was no clinical evidence of meningeal involvement. Previous investigation[7] revealed abnormal cerebrospinal fluid in 16.4 per cent of 1,380 patients with untreated early syphilis. It was thought that by the intravenous administration of massive amounts the penicillin might surmount the hematoencephalic barrier and circulate through the cerebrospinal fluid system.

The patients received sodium penicillin by the continuous intravenous drip method in amounts ranging from 10 million to 25 million units over a twenty-four hour period. The total amount of penicillin was contained in 1,000 cc. of isotonic solution of sodium chloride.

The administration of penicillin by the intravenous drip technic is known to cause thrombophlebitis;[8] therefore an attempt was made to circumvent this complication by the use of the anticoagulant heparin incorporated in the "Pitkin menstruum"[9] Three hundred mg. of heparin was injected subcutaneously into the anterolateral aspect of the thigh immediately before the institution of penicillin therapy.

The patients were given the intravenous drip by the usual technic utilizing veins of the forearm. The rate of flow of the solution was regulated by means of a pinch clamp to deliver 1,000 cc of solution continuously over a twenty-four hour period.

The levels of penicillin in the blood and cerebrospinal fluid were determined by the method described by Rosenblatt, Alture-Werber, Kashdan and Loewe[10] at intervals of six hours during the drip procedure and six hours after completion of therapy. All blood specimens were kept in the refrigerator until immediately before setting up the tests, which were run daily. The serums were removed by centrifugation and tested for penicillin activity by a tube dilution technic using Streptococcus pyogenes, strain C-203, group A, as the test organism. The calcium salt of penicillin supplied by the Food and Drug Administration was used as a reference standard.

The specially prepared penicillin utilized in these investigations was supplied by Mr. John L Smith of the Charles Pfizer and Co Inc

Because of lack of space, this article is abbreviated here by the omission of tables giving the penicillin levels in patients receiving 10, 15, 20 and 25 million Oxford units

From the office of the President of the Chicago Board of Health and the Chicago Intensive Treatment Center, Venereal Disease Control Program, in cooperation with the United States Public Health Service

Valuable advice was given by Dr Philip Rosenblatt Loyal assistance was given by Drs H C McCraney and Lydia Marshak The work was made possible with the help of a technical group consisting of Elsie Miller, B A., Ellen Bienfang, R N, and Mary Gleason

[10] Rosenblatt, P.; Alture Werber, E; Kashdan, F., and Loewe, L· A Method for the Determination of Penicillin Levels in Body Fluids, J Bact **48**:599 (Nov) 1944.

A lumbar puncture was performed within thirty minutes of completion of treatment and the penicillin concentration of the cerebrospinal fluid determined.

It was decided, after the first 25 patients had been studied, to determine the level of penicillin in the blood only twice during the period of treatment, at twelve and twenty-four hours after the institution of therapy.

Penicillin was demonstrated in measurable concentration in the cerebrospinal fluid of 126 of the 162 patients (77.7 per cent). These 126 comprised 48 of the 53 (91 per cent) patients who had received over 10 million units of penicillin and 78 of the 109 (71.5 per cent) patients treated with 10 million units of penicillin. The concentration of penicillin ranged from 0.02 to 0.55 Oxford unit per cubic centimeter. Patients receiving 10 or 15 million units showed 0.10 or below with 2 exceptions, and 49.3 per cent of the specimens on the 10 million group reveal 0.02 to 0.03 Oxford unit. The highest level, 0.55 Oxford unit, was obtained for 1 patient on the 25 million unit schedule. The range in levels for the 9 patients with abnormal cerebrospinal fluids was from 0.02 to 0.40 Oxford unit.

No conclusive evidence was established as to the relationship of body weight to levels of penicillin in the cerebrospinal fluid.

There was a direct relationship between the total dosage and the level of penicillin in the cerebrospinal fluid, as shown in the table.

The relationship between the amounts of penicillin in the cerebrospinal fluid and the blood was not clearly established, although some tendency was indicated. Thirty-one patients of the 109 (28.4 per cent) treated with 10 million units had no penicillin activity in the cerebrospinal fluid. Twenty-four of this group (77.4 per cent) had 20 units of penicillin or less in the blood. Seventy-eight (71.5 per cent) patients did have penicillin activity in the cerebrospinal fluid. Thirty-seven (47.4 per cent) of this group had 20 or more units of penicillin in the blood

Concentration of Penicillin in the Cerebrospinal Fluid

Oxford Units per Cubic Centimeter

Total Dose of Penicillin in Million Oxford Units	Maximum	Minimum	Average	Per Cent of Patients Showing Penicillin
10	0.30	0.00	0.029	71.5
15	0.12	0.00	0.048	70.6
20	0.40	0.025	0.043	100.0
25	0.55	0.01	0.213	100.0

An analysis of blood levels taken six hours after treatment was completed showed detectable penicillin in only 7 of 31 patients studied.

COMMENT

Clinical improvement has been observed in the penicillin treatment of the purulent meningitides,[11] neurosyphilis [12] and brain abscess,[13] but there are few studies on the levels of penicillin in the cerebrospinal fluid.

The importance of attaining an effective therapeutic level of penicillin in the cerebrospinal fluid in those diseases in which it is desirable that the drug arrive at the site of the pathologic process cannot be overemphasized.

As the instillation of penicillin directly into the cerebrospinal fluid via lumbar, cisternal or ventricular puncture is technically difficult and often hazardous,[14] the achievement of an effective therapeutic penicillin level by the intravenous method of administration is of prime importance.

Reactions were encountered in some patients during and after treatment consisting of thrombophlebitis, nausea, vomiting and azotemia. These will be presented in detail in a subsequent report. No fatalities occurred and no convulsions or signs of meningeal irritation were observed.

SUMMARY

Patients with early syphilis were given penicillin by the continuous intravenous drip technic in amounts varying from 10 to 25 million units in a period of twenty-four hours.

Significant quantities of penicillin were demonstrated in the cerebrospinal fluid in the majority of the patients.

Clinical Notes, Suggestions and New Instruments

ENDOMETRIOSIS CAUSING INTESTINAL OBSTRUCTION

OSCAR T. WOOD, M.D., IRVIN DEIBERT, M.D., and
THOMAS KAIN, M.D.
Philadelphia

Endometriosis externa occurs not infrequently. This condition is usually seen involving the oviducts, pelvic peritoneum, rectum and mesorectum.[1] It has also been seen involving the ileum, appendix, cecum, ureter, bladder and skin surfaces particularly in the region of the umbilicus and in old operative scars of the anterior abdominal wall. Green-Armytage [2] reports the general incidence of endometriosis as 8.9 per cent in 1,000 surgical cases.

Endometrial implantation means that there is primary seeding from the site of origin. Endometrial transplantation means that there is secondary embedding from an implant. The case reported here represents endometriosis externa of the implant type.

With the exception of rectum and mesorectum, intestinal contaminations are all derived primarily from the tubal "spill" or secondary rupture of endometrial cysts. Every transplant or implant on a free peritoneal surface becomes a potential center for further transplants.

When a group of endometrial cells settles on a favorable surface, fixation occurs followed by invasion. A small operculum in the peritoneum by which the invasion was made soon closes over and a potential endometrial cavity is formed. These tissues tend to develop their original architecture. A menstruation diapedesis occurs in this potential cavity at the next menstrual epoch, and rupture at any subsequent menstruation is a possibility. Parts of the gastrointestinal tract most susceptible to these transplantations or implantations are the sigmoid, rectum, appendix, cecum and the lower part of the ileum.[1]

Intestinal obstruction as a result of endometriosis has been observed frequently. Most instances, however, are those involving the sigmoid and mesorectum. Relatively few cases of acute complete obstruction have been recorded in the literature. Glenn and Thornton[3] report 2 cases of partial intestinal obstruction of the chronic type due to endometrial implantation.

Masson[4] reports 689 organs of 576 patients with endometriosis. Most of the structures involved were pelvic genital organs. The intestines were involved in 17 instances; of these the colon was involved 14 times, the appendix twice and the ileum once. Keen and Kimbrough[5] did not find the small bowel involved in any of 118 proved cases of endometriosis, nor did Cullen[6] in reporting personal observations over a twenty-five year period. A review of the English literature over a twenty-five year period revealed only 4 cases of endometrial implants involving the small bowel and producing varying degrees of obstruction, none acute. However, the true incidence of endometrial implants in the small bowel is unknown.

This case is worthy of recording because of the short duration of symptoms from the time of onset. Also this patient had an appendectomy performed fifteen years previously, at which time no pathologic state other than acute appendicitis was observed. Furthermore, it represents an instance of acute complete obstruction due to endometriosis which necessitated resection of a part of the ileum.

REPORT OF CASE

A white woman aged 38, first seen by us on Dec. 31, 1944, complained of midepigastric pain, nausea and vomiting.

Her past history was negative except for scarlet fever at 16 years, a submucous resection in 1926, an appendectomy in 1930 and a tonsillectomy in 1931.

Menstruation started at the age of 13. The flow was moderate. There was always slight dysmenorrhea; the cycle was twenty-one to thirty-one days. There were no pregnancies, miscarriages or abortions. No intermenstrual discharge or pain was elicited.

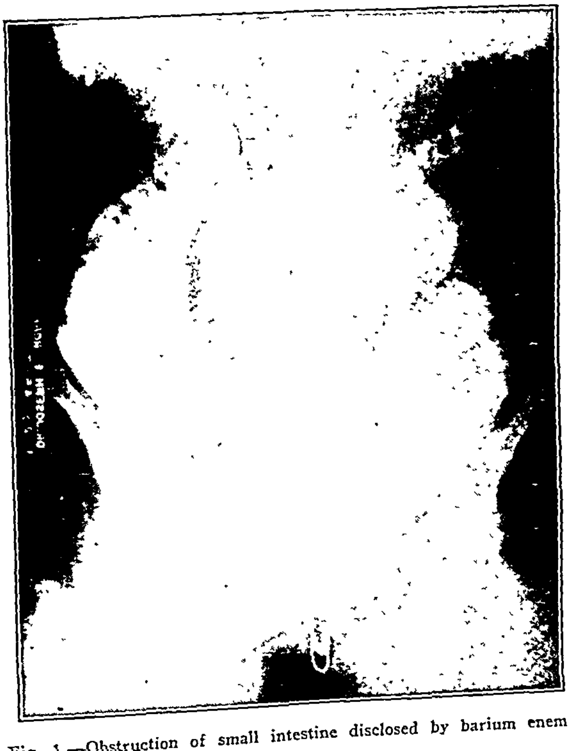

Fig. 1.—Obstruction of small intestine disclosed by barium enema..

She stated that her first attack of pain was on Nov. 19, 1944 at the time of her regular period. This pain was continuous and quite severe. It lasted until her period stopped. For the remainder of November and also during her December period she had no pain. On December 31 she started to menstruate again, and the same pain recurred. She vomited and was somewhat relieved. The pain continued, however, for the full duration of her period. Since this pain was midepigastric and at times radiated to her back and right subscapular region, it was necessary to rule out peptic ulcer and cholelithiasis.

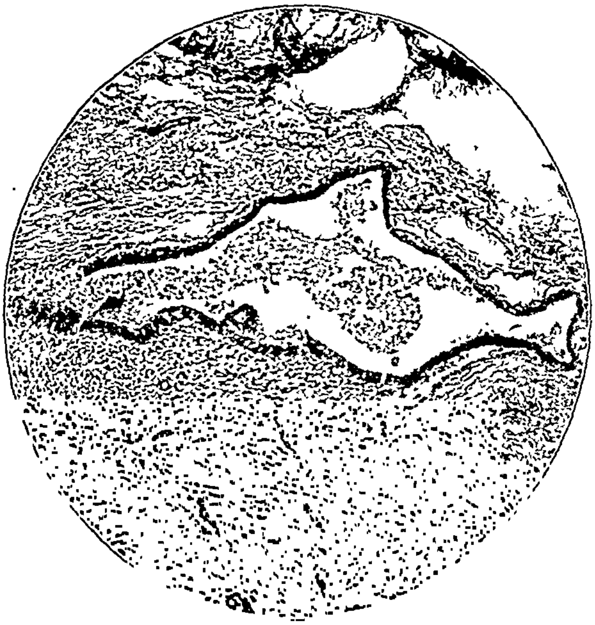

Fig. 2.—Section of ileum, slightly reduced from a photomicrograph with a magnification of 100 diameters.

An upper gastrointestinal series and cholecystogram were negative. Gastric analysis was normal. Antispasmodics and sedation were prescribed during the following intermenstrual period, and the patient was without symptoms. There were no tarry stools, the vomitus was never bloody nor was the patient jaundiced at any time.

On Jan. 27, 1945 the patient began to menstruate. At this time she also developed severe right lower quadrant pain, abdominal distention, nausea and vomiting. It became evident that she was having some sort of small bowel obstruction. Peristalsis was hyperactive with gurgling. Tympanites was present and the pain soon became generalized. The temperature was 100 F., and white blood cells numbered 10,000. Morphine sulfate ¼ grain (0.016 Gm.) hourly was required for relief of pain. A gastrointestinal series with barium enema was performed (fig. 1) and established the diagnosis of small bowel obstruction. Laparotomy was performed by Dr. Deibert as follows:

Under spinal procaine anesthesia a right rectus incision was made. The omentum was found to be adherent to the parietal peritoneum. These were incised and the contents of the abdominal cavity were found to be normal, except for the terminal ileum, which showed what appeared to be a hard constricting band of fibrous tissue about 3 inches from the ileocecal junction. This completely occluded the lumen of the bowel. A resection of the involved portion was done and a side to side anastomosis of the ileum and cecum was performed. Convalescence was uneventful.

Review of histologic sections (fig. 2) by Dr. Read revealed the following:

Diagnosis: Endometriosis of the ileum.

Gross: The specimen was 6 cm. of small bowel. The mucosal surface appeared relatively normal, but there was thickening and distortion of the serosa.

Microscopic: The section was of ileum. The mucosa and submucosa were relatively normal. The muscularis showed hypertrophy and here, but more particularly in the serosa, there were small collections of simple glands surrounded by stroma. There were erythrocytes in the lumen of some of the glands. The lesion was endometriosis of the serosa of the ileum.

---

COMMENT

In a case of acute intestinal obstruction involving the terminal ileum, the cause was endometriosis. The symptomatology at first suggested cholecystic disease or peptic ulcer. The history was typical of endometriosis, the attacks coinciding with the menstrual periods. As noted, this is an unusual type of complete small bowel obstruction.

Council on Pharmacy and Chemistry

REPORT TO THE COUNCIL ON PHARMACY AND CHEMISTRY

Six drug manufacturers interested in thiouracil have cooperated with the Food and Drug Administration to prepare a survey by questionnaire of the toxicity of this drug. The study involved the results of the use of thiouracil in 5,745 cases and was undertaken before the drug became available in interstate commerce. When the survey was completed it was reported to the Council on Pharmacy and Chemistry with a view to informing this body, and through it the medical profession, of the status of thiouracil. The Council warmly commends such cooperation and urges that manufacturers show a similar spirit in other therapeutic problems of common interest. When physicians are supplied with potent drugs they must also be supplied with adequate information concerning their actions, use and dangers.

AUSTIN SMITH, M.D., *Secretary*,

THE CLINICAL TOXICITY OF THIOURACIL

A Survey of 5,745 Cases

WALTON VAN WINKLE JR., M.D.
Washington, D. C.
STANTON M. HARDY, M.D.
Pearl River, N. Y.
GEORGE R. HAZEL, M.D.
North Chicago, Ill.
DON CARLOS HINES, M.D.
Indianapolis
H. SIDNEY NEWCOMER, M.D.
New York
E. A. SHARP, M.D.
Detroit
and
W. N. SISK, M.D.
Kalamazoo, Mich.

Because of the difficulty of determining from reports in the literature the incidence and severity of the toxic reactions resulting from the administration of thiouracil for the treatment of hyperthyroidism, a survey by questionnaire has been made of 5,745 patients treated by 328 clinical investigators. The results derived from this survey have been analyzed by statistical methods and constitute the basis of this report.

Data obtained by questionnaire are subject to certain inherent errors. Failure to answer a question, misinterpretation of a question and accidental insertion of an incorrect figure are among the sources of error in organizing such statistics. The necessity for arbitrary grouping and condensation of data and the inability to reflect secondary factors influencing the answer to a given question contribute to the errors of analysis. Some of these deviations can be held to a minimum by careful phrasing of the questionnaire and by intelligent interpretation of the answers. In a consideration of the data presented here, therefore, these inherent errors must be borne in mind although accepted statistical methods were used in their organization so as to limit the deviations to an irreducible minimum. It is believed nevertheless that the trends disclosed and the conclusions reached as a result of this survey are correct, even though the statistics are subject to the errors mentioned.

CLINICAL MATERIAL AND THERAPEUTIC APPRAISAL

The material which forms the basis for this report is derived from large clinics, from small clinics and from individual practitioners. Some of the patients were subjected to the closest scrutiny, which included repeated and extensive laboratory studies; others were followed in less detail.

Many patients were hospitalized, but many were ambulatory during treatment. Despite these variations, it is believed that the results of this survey represent closely those which may be expected when thiouracil becomes generally available to all physicians.

Since the clinical safety of any potent therapeutic agent should be appraised only in the perspective of its therapeutic usefulness, certain information regarding the value of thiouracil in the treatment of hyperthyroidism was collected. Published reports leave little doubt that in most instances the administration of thiouracil can bring about a remission of the hyperthyroid state. Its usefulness in other conditions associated with derangements of thyroid activity has not been completely evaluated.

This survey revealed that thiouracil is effective against all types of hyperthyroidism whether these are represented by diffuse or by nodular goiters and regardless of the number of nodules. Thiouracil may also be of value in the treatment of acute thyroiditis, although data on this condition are scanty. The drug has been tried and found to be of no value in simple goiter. It has been tried without any useful effect in conditions with related symptomatology but where no hyperthyroidism exists.

An attempt was made to determine what, if any, factors contributed to a successful outcome of thiouracil therapy. The incidence of failure to respond to thiouracil has been correlated with such factors as dose, duration of treatment, and whether iodine therapy had been used prior to thiouracil. Only those cases in which thiouracil was used for treatment of hyperthyroidism are considered and failures directly attributable to toxic reactions are not included in the accompanying tabulations.

A correlation could not be established between either the initial dose or the maintenance dose and the incidence of failure. The number of cases in which 0.1 Gm. per day was given as an initial dose is too small to be statistically significant. The majority of investigators used either 0.4 Gm. per day or 0.6 Gm. per day, and since the results are as satisfactory at the lower figure as at the higher, it would appear preferable to recommend 0.4 Gm. per day as the initial dose.

Clinical experience has shown that thiouracil should be administered in divided doses throughout the twenty-four hour period. Administration only once a day is generally followed by poor results. For best results it is suggested that the total daily dose be divided into three or four parts which are administered at equal intervals during the waking hours.

It has been a common observation that a clinical response to thiouracil may not be seen for several weeks

---

Miss Lila Knudsen and Mr. Pete James of the Food and Drug Administration tabulated the data and supplied the statistical analysis.

From Drug Division, Food and Drug Administration, Federal Security Agency, and the Medical Departments of Lederle Laboratories, Abbott Laboratories, Eli Lilly & Co., E. R. Squibb and Sons, Parke Davis & Co, and the Upjohn Company.

after treatment is started. In this survey there were 209 failures reported in which the duration of treatment was given. Chart 1 shows that the incidence of successful treatment increased as the duration of treatment was prolonged. No explanation is apparent for the low incidence of success at six months, but the figure for thirteen months was derived from too small a number of patients to be significant. To emphasize the desirability of prolonged treatment before classifying a lack of response as a failure, it was observed that in 34 per cent of those patients reported as failures, treatment was discontinued before the eighth week.

TABLE 1.—*Failures of Thiouracil Therapy in Relation to Initial Dose of Thiouracil*

Initial Dose, Gm. per Day	Total Cases	Failures	
		Number	Per Cent
0.1	35	0	0.0
0.2	268	9	3.4
0.3	187	12	6.4
0.4	669	30	4.5
0.5-0.6	3,448	135	3.9
0.7-0.9	504	32	6.3
1.0 or over	622	31	5.0
Total........	5,733	249	4.3

It is not uncommon for a patient to show no response to thiouracil in the first four to eight weeks of treatment if iodine had previously been administered or if the gland was large and soft. It is noteworthy, therefore, that of the 71 failures which occurred during the first eight weeks 70 per cent had had iodine therapy prior to thiouracil treatment. This suggests that some might have responded satisfactorily if the medication had been continued for longer periods.

It was not possible to obtain reliable figures on the incidence of remissions induced by thiouracil. By remission is meant absence of symptoms and a basal metabolic rate within the normal range after the drug was discontinued. The majority of investigators did not terminate treatment except in those cases in which thyroidectomy was performed; hence there is no way to determine the duration of remission without the drug. It is evident, however, that of the 1,236 remissions reported in the series 33.7 per cent had relapsed at the time of inquiry. Remissions as long as a year or more have been reported, but the average relapse occurred in about twenty weeks. Hence, until more is known regarding the conditions influencing both remission and relapse, it is futile to speculate on this problem.

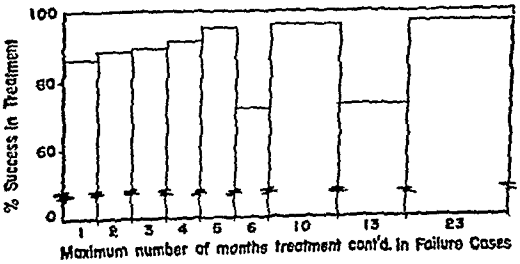

Chart 1.—Relation of satisfactory response to thiouràcil to duration of treatment.

TYPE AND INCIDENCE OF TOXIC REACTIONS

The principal toxic reactions observed following medication with thiouracil are granulocytopenia, leukopenia, drug fever and dermatitis. At least twenty-seven other reactions were recorded, of which only eight were observed in more than 2 cases. This suggests that most of the reported side reactions other than those specifically named or the eight mentioned later were not related to thiouracil medication.

Twenty-eight investigators reported that the drug occasionally produced nausea sometimes accompanied by dizziness, headache or abdominal cramps. Parotitis and joint pains have each been reported by seven investigators. Purpura was reported by six, jaundice by four, diarrhea by four, thyroiditis by three and secondary anemia by three investigators. Edema, particularly of the extremities, has been mentioned by several investigators as occurring during therapy. It is not clear in all cases that this was due either directly to the drug or to the rapid metabolic and circulatory changes resulting from correction of the hyperthyroidism.

The eight complications of low incidence may or may not be related to administration of thiouracil, since these reactions did not occur with a frequency greater than expected in 5,000 persons selected at random and observed for a period of six months to a year. It is recommended, however, that these complications should be watched for, since it cannot definitely be proved that the drug was not the responsible agent.

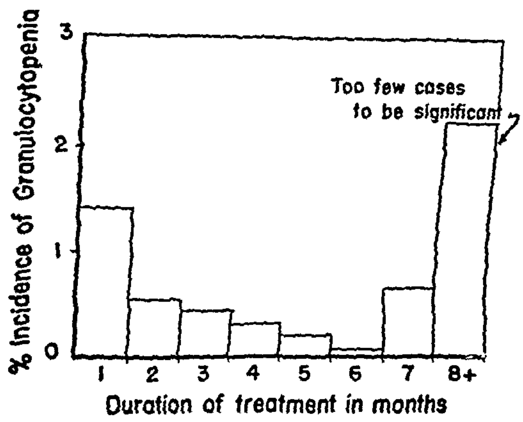

Chart 2.—Relation of incidence of granulocytopenia to duration of treatment.

In the series studied in this investigation, 752 cases in which one or more side reactions occurred were reported. This represents an incidence of 13.1 per cent. These complications were considered by the investigators as severe enough to warrant discontinuance of therapy of 452 patients, or 60.1 per cent of those showing some side reaction.

GRANULOCYTOPENIA

Since the most serious complication of thiouracil therapy appears to be granulocytopenia, it was pertinent to inquire concerning the frequency of this complication and whether its occurrence could be correlated with the dose, duration of treatment or other factors. A diagnosis of granulocytopenia was accepted if the total white count was below 4,000, the granulocytes particularly diminished and associated with sudden onset and acute symptoms such as fever, sore throat, prostration and malaise. Unfortunately not all cases of apparent malignant granulocytopenia are clearly distinguishable from simple neutropenia, particularly in the early stages. The investigators reported 168 cases of granulocytopenia, but only 142 of these could clearly be classed as the frank malignant type. The remaining 26 cases appeared to be early cases or atypical simple leukopenia with neutropenia, but because the investigators classed them as granulocytopenia they are included as such in these tabulations. The 142 cases of granulocytopenia represent an incidence of 2.5 per cent of this complication and accounted for about 22 per cent of all toxic reactions.

Table 2.—*Incidence of Granulocytopenia During Thiouracil Therapy in Relation to Initial Dose of Drug*

Initial Dose, Gm. per Day	Total Cases	Granulocytopenia: Number of Cases	Granulocytopenia: Per Cent of Total Cases
0.1-0.4	1,159	33	2.8
0.5-0.6	3,448	109	3.2
0.7-0.9	504	14	2.8
1.0 and over	612	12	2.0

It can be seen from table 2 that there is no significant relationship between the incidence of granulocytopenia and the dosage of thiouracil. There was, however, a very clear relationship between the duration of treatment and the occurrence of this complication. Chart 2 shows that the incidence of granulocytopenia was greatest during the first four weeks of treatment and declined progressively thereafter. The incidence of this complication in the first month of treatment was 1.4 per cent, and more than one half of all the cases occurred during this period. Seventy per cent of the cases of granulocytopenia occurred by the end of the eighth week of treatment. No apparent explanation was found for the high incidence during the seventh month of treatment, but it is suggested that some patients may have lapsed in treatment at this time, and it is generally believed that resumption of therapy after such a lapse may predispose the patient to this complication.

One case of agranulocytosis was reported to have occurred during the fifty-sixth week of treatment, and 1 case, not included in these tabulations, was reported to have occurred six months after discontinuance of treatment. The first case may also have occurred after a temporary discontinuance of therapy.

There were twenty-one deaths, all attributable to agranulocytosis, establishing a mortality rate of 0.4 per cent for the entire series and a case fatality rate for agranulocytosis of 14 per cent. From the information available in the literature and that obtained in this survey, the most effective treatment of agranulocytosis due to thiouracil appears to be the parenteral administration of massive doses (500,000 units per day) of penicillin, and some investigators suggest repeated transfusions of small amounts (200 to 300 cc.) of whole blood. However, there are some who are not in favor of unnecessarily frequent blood transfusions because it has been shown statistically that repeated transfusions increase the risk of transfusion reaction. There is no satisfactory evidence that pantothenic acid, pyridoxine, folic acid, vitamins or pentnucleotide influence the outcome of this disease or aid in preventing such reactions. The most important factor in the control of granulocytopenia resulting from thiouracil therapy appears to be discontinuance of therapy at the earliest sign of this complication and prompt institution of vigorous treatment. It is imperative that the patient be instructed to stop the drug and report immediately to the physician if symptoms such as sore throat, fever, coryza or malaise are noted. The value of repeated blood counts is emphasized by the fact that 1 patient was found to have a complete absence of granulocytes three days before any symptoms developed.

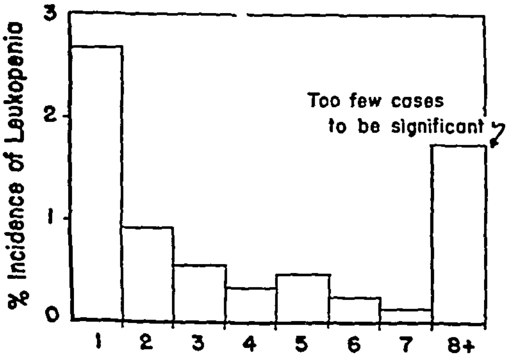

Chart 3.—Relation of leukopenia to duration of treatment.

LEUKOPENIA

One third of all the reported toxic reactions consisted of a leukopenia. In many instances it was difficult to distinguish between a simple leukopenia and an early malignant granulocytopenia. In this survey a designation of simple leukopenia was made when the total white blood cell count was below 4,000, the differential count was relatively normal and the patient showed no subjective symptoms. It may be questioned whether all the cases of leukopenia reported were actually caused by thiouracil administraion, since hyperthyroidism itself predisposes toward a leukopenic state. However, there seems to be a clear relationship between the administration of the drug and the onset of this complication, and it is felt that any reduction in total white count while the patient is under treatment with thiouracil should be viewed seriously.

Table 3.—*Incidence of Leukopenia in Relation to Initial Dose of Thiouracil*

Initial Dose, Gm. per Day	Total Cases	Leukopenia Cases	Per Cent Incidence
0.1-0.4	1,159	58	5.0
0.5-0.6	3,448	119	3.5
0.7-0.9	504	44	8.7
1.0 and over	622	30	4.8

Of the 251 cases of leukopenia reported in this series, 234 lend themselves to fairly detailed analysis. This complication had an overall incidence of 4.4 per cent. From table 3 it may be seen that dosage bore no relationship to the incidence of leukopenia. The relationship between incidence and duration of treatment is shown in chart 3 and resembles closely that of granulocytopenia. The incidence of leukopenia in the first four weeks was 2.7 per cent, and 60 per cent of all these cases occurred during this period. Seventy-five per cent had occurred by the end of eight weeks and 95 per cent by the end of six months.

In a number of cases in which leukopenia developed, administration of thiouracil was continued and in nearly half of these a gradual return of the white cell count to normal limits was observed. No reliable figures were obtained on the seriousness of this complication, and it appears that in some instances it may not be harmful to the patients. However, since it cannot be predicted which case may or may not have a serious prognosis, it would seem imperative either to discontinue treatment or have the patient report to the physician at frequent intervals for repeated examinations of the blood. Hospitalization of the patient should be considered if examination reveals a decided reduction in granulocytes.

This precaution is further emphasized by the fact that although 121 patients developed granulocytopenia without a previous leukopenia, and 198 patients developed a leukopenia which did not pass into a granulocytopenia, 47 patients had both complications. If these two complications were to occur in the same individual purely on the basis of chance, it would be expected that these would occur in not more than 7 or 8 patients in a series of the size studied. The actual incidence was six and one-half times the expected incidence, and this difference, when tested by statistical methods, was found to be highly significant ($P<0.001$). This suggests that all patients who develop a leukopenia during therapy should be closely watched.

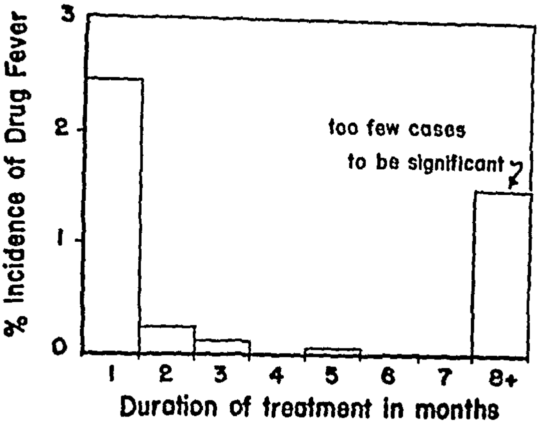

Chart 4.—Relation of drug fever to duration of treatment.

DRUG FEVER

Drug fever is a reaction not infrequently seen following therapy with a wide variety of substances. It is not surprising, therefore, that this complication was reported in 154 individuals following thiouracil therapy. The incidence of this reaction amounted to 2.7 per cent of all cases and accounted for 20.5 per cent of all toxic reactions. By reference to table 4 it is evident that dosage did not influence the incidence of this reaction. Furthermore, this reaction usually occurs early in the course of therapy, as is shown in chart 4.

Table 4.—*Incidence of Drug Fever in Relation to Initial Dose of Thiouracil*

Initial Dose, Gm. per Day	Number of Cases	Cases with Drug Fever	Per Cent Incidence
0.1-0.4	1,159	37	3.2
0.5-0.6	3,418	86	2.5
0.7-0.9	604	10	2.0
1.0 and over	622	21	3.3

Thirty per cent of these reactions occurred in the first week of therapy and 85 per cent had occurred by the end of the fourth week. Nearly 10 per cent of the cases of drug fever were observed in the first forty-eight hours, and, if the patient was retested with the drug, fever usually occurred in less than twelve hours. An interesting observation made by several investigators was that when drug fever occurred early in therapy it was usually a more severe reaction, with temperatures as high as 106 F. reported in some instances. In those instances in which the fever was seen during the later stages of therapy, the temperature seldom exceeded 102 F. and the entire reaction was of a milder nature. Since a fever is part of the syndrome of agranulocytosis, any patient receiving thiouracil who develops a fever should be examined immediately and white blood cell and differential counts should be obtained in order to rule out agranulocytosis before classifying the fever as a temperature reaction only.

SKIN REACTIONS

The skin reactions which occurred during thiouracil therapy were varied and usually of a mild nature. One hundred and eighty-nine instances of these complications were observed, an incidence of 3.3 per cent. One fourth of the adverse reactions from thiouracil were skin reactions. The frequency of the various types of skin reaction are given in table 5. As might be expected, dosage had no influence on the incidence, and although there was some tendency for the reactions to occur early in treatment, particularly if other complications occurred in the same patient, the relationship between duration of treatment and incidence was not as striking as that seen with the other complications.

Table 5.—*Skin Reactions from Thiouracil Therapy in 5,745 Patients*

	Cases
Urticaria	64
Papular rash	37
Morbilliform rash	23
Erythema	18
Macular rash	17
Acneform rash	3
Pruritus	3
Edema of legs	1
Unspecified dermatitis	23

Table 6.—*Opinions on Relative Safety of Thiouracil*

Is the incidence of toxic reactions to thiouracil greater or *less* than complications of present methods of treating hyperthyroidism?

Answer	Per Cent of Investigators
Less	78.6
Greater	4.2
No opinion	17.2

Although none of the skin reactions were reported as serious, the occurrence of urticaria cannot be regarded as an innocuous reaction. In the case of the sulfonamides such reactions have frequently been associated with more severe complications; hence it would seem advisable to discontinue thiouracil therapy or proceed with great caution if the patient shows an allergic response.

Because of relatively high incidence and severity of the toxic reactions following thiouracil therapy, an attempt was made to poll the investigators regarding their opinions of the relative safety of this drug. The following question was asked:

> In your opinion is the incidence of toxic reactions greater than the incidence of bad results (including postoperative thyroid crisis, injury to recurrent laryngeal nerve, parathyroid tetany and other operative complications; uncontrolled or fatal thyrotoxicosis in patients in whom operation is inadvisable or contraindicated) seen with other methods of treatment?

The answers to this question are summarized in table 6. It is apparent that the large majority of those who have had experience with thiouracil feel that it offers a definite advantage over present methods of treatment of hyperthyroidism from the standpoint of safety.

SUMMARY AND RECOMMENDATIONS

On the basis of this survey covering the experience of 328 investigators in 5,745 cases, the following recommendations appear justified:

1. Thiouracil is effective in the management of thyrotoxicosis and possibly thyroiditis.
2. Thiouracil is of no value and should not be used in other derangements of thyroid activity or in conditions not associated with hyperthyroidism.
3. More information should be secured concerning the induction of remissions by thiouracil and the factors affecting the permanence of these remissions.
4. At present the optimum dosage schedule appears to be 0.4 Gm. per day, in divided doses initially, and after the symptoms are controlled or the basal metabolic rate is within the normal range the dose should be reduced to 0.1 or 0.2 Gm. per day. More information is needed on the effectiveness of lower doses.
5. On the basis of the available information, it can be recommended only that thiouracil be used for preoperative treatment or for those patients for whom operation is contraindicated. The wisdom of depending on thiouracil as a substitute for operative procedure can be determined only by following the results of investigations carried on for longer periods.
6. Many patients, particularly those who have received previous iodine therapy, do not respond immediately to thiouracil therapy; hence medication should be continued for at least thirty days, or, for a patient to whom iodine has been administered, for sixty to one hundred days, before concluding that no response to thiouracil is possible.
7. Approximately 13 per cent of all cases can be expected to show some adverse reaction to thiouracil therapy.
8. The most frequent and severe complications of thiouracil therapy are granulocytopenia, leukopenia, drug fever and dermatitis. The appearance of jaundice, purpura and anemia has been reported and should be watched for and, if observed, calls for careful evaluation of the clinical condition of the patient before thiouracil therapy is resumed.
9. Granulocytopenia occurs in about 2.5 per cent of cases and is the most serious complication of thiouracil therapy. This reaction tends to occur in the early weeks of treatment, and 80 per cent of the cases were seen by the twelfth week of therapy. No relationship to the dose of thiouracil was apparent. Treatment of this complication should consist of massive doses of penicillin (500,000 units per day).
10. Leukopenia had an incidence of 4.4 per cent, seen early in treatment, 75 per cent occurring in the first eight weeks but not related to dosage. More information is needed on the relationship between leukopenia and granulocytopenia.
11. Drug fever had an incidence of 2.7 per cent, seen very early in treatment, 85 per cent occurring in the first four weeks but not related to dosage. Reactions occurring early tended to be more severe than those occurring late in treatment.
12. Skin reactions had an incidence of 3.3 per cent. Urticaria was the most common, but a wide variety of other dermatoses were seen. None were deemed serious, but caution is advised in continuing therapy in the presence of these complications.
13. Three fourths of the investigators were of the opinion that the incidence of adverse reactions of thiouracil was less than the incidence of complications from present methods of treatment.
14. It should be emphasized that patients receiving thiouracil therapy should be carefully watched, especially during the first twelve weeks of therapy. Patients should be instructed to report immediately to their physician if any adverse symptoms such as sore throat, fever, coryza or malaise are experienced.
15. Since the mild and the juvenile types of hyperthyroidism can frequently be controlled adequately by iodine therapy alone, thiouracil should not be used for these patients unless the safer form of therapy proves ineffective.

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin Smith, M.D., *Secretary.*

CONTRACEPTIVE JELLIES AND CREAMS (See New and Nonofficial Remedies, 1945, p. 355).

The following article has now been accepted:

Holland-Rantos Co., Inc., New York

U. S. trademark 213,756.

Koromex Jelly: A water soluble jelly formed from tragacanth and gum acacia having a p_H of 4.6, prepared from the formula:

	Per Cent
Boric acid	2.0
Oxyquinoline benzoate	0.02
Phenylmercuric acetate	0.02
Glycerin	10.0
Gum acacia	0.6
Tragacanth	2.5
Perfume	0.015
Butyl parahydroxybenzoate as preservative	0.02
Water	100

Actions and Uses.—See article Contraceptive Jellies and Creams.

Dosage.—5 cc.

SYRINGE APPLICATORS FOR CONTRACEPTIVE JELLIES AND CREAMS (See New and Nonofficial Remedies, 1945, p. 357).

The following article has been accepted:

Holland-Rantos Co., Inc., New York

Koromex Vaginal Applicator: A transparent plastic tube threaded at the blunt, intravaginal end, to screw onto tubes of Koromex Jelly to permit filling by compression of the tube. The full capacity is 5 cc., the recommended dose.

ACETARSONE (See New and Nonofficial Remedies, 1945, p. 235).

The following dosage form has been accepted:

Allen Laboratories, Inc., Palmer, Mass.

Allen Brand Tampon with Acetarsone (Stovarsol): A lightly compressed stitched tampon of absorbent cotton, coated with 0.1 Gm. of powdered acetarsone, to which is attached a tablet consisting of acetarsone 32 mg. in a tablet base composed of lactose, dextrose, boric acid and starch with a small quantity of sodium bicarbonate and tartaric acid to aid disintegration.

Actions and Uses.—(See article on Acetarsone.)

Dosage.—Intravaginally, one tampon tablet every other day or daily, followed by a mildly acid douche after a third treatment or after a week's treatment, has been reported to give satisfactory results.

THIAMINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1945, p. 610).

The following dosage form has been accepted:

Frederick Stearns & Co., Detroit

Tablets Thiamine Hydrochloride: 3 mg.

SATURDAY, FEBRUARY 9, 1946

NONTUBERCULOUS PULMONARY CALCIFICATION

Although pulmonary calcification has been generally interpreted as evidence of healed tuberculosis, we recognize now that this disease is not the only important cause of such lesions. Recent epidemiologic studies have shown that a large proportion of persons with pulmonary calcification have negative tuberculin reactions. Lumsden and his associates[1] concluded, after a careful epidemiologic study of Coffee County in southwestern Alabama and Giles County in south central Tennessee, that skin testing with any of the tuberculosis preparations available, as a sole means of establishing an epidemiologic index or rate of incidence of tuberculous infection in a community or in a region, is of doubtful value or definitely futile. Smith[2] suggested that the area of high prevalence of pulmonary calcification and tuberculin negative reactors corresponds with the endemic area of histoplasmosis. Palmer[3] found in a study in which 3,000 nurses in Detroit, Kansas City, Minneapolis and Philadelphia were given intradermal tuberculin and histoplasmin tests and chest roentgenograms that (*a*) mild, probably subclinical, infection with Histoplasma capsulatum (or an immunologically related organism) is widely prevalent in certain states and relatively infrequent in others; (*b*) in general those states in which the frequency of reactions to histoplasmin is high are those in which pulmonary calcification is also high and (*c*) a high proportion of the pulmonary calcifications observed in roentgenograms of tuberculin negative persons is due not to tuberculosis but probably to histoplasmosis.

Christie and Peterson[4] studied a group of 181 children from a children's home in Williamson County, Tenn. Forty-five, or 24.9 per cent, of these reacted to tuberculin; 133, or 73.5 per cent, reacted to histoplasmin, and 79, or 43.6 per cent, had pulmonary lesions interpreted as calcifications. Almost twice as many children had calcification as were tuberculin positive. Positive reactions to histoplasmin were three times as common as positive reactions to tuberculin. Among the youngest group, 41.7 per cent of those under 5 years gave positive reactions to histoplasmin. None of the children under 5 years of age reacted positively to 0.1 mg. of tuberculin. The reactivity to histoplasmin occurred at an earlier age than the appearance of calcium in the lungs or reactivity to tuberculin. Apparently pulmonary calcification occurs less commonly in relation to tuberculin sensitivity than in relation to histoplasmin sensitivity. Of the 78 children with pulmonary calcification 25, or 32 per cent, reacted to 1 mg. or less of tuberculin. There were 53 children who did not react to tuberculin, more than twice as many as did react. Of the whole group 68, or 87.2 per cent, reacted to histoplasmin.

The studies by Gass and his associates and by Lumsden and his associates showed that there is a much greater prevalence of this phenomenon of pulmonary calcification in persons who are not sensitized to tuberculin in the area of the eastern slope of the Mississippi River basin and the adjacent states of the western slope south of Iowa than in the rest of this country. In this general area the overall prevalence of pulmonary calcification varied from 27 per cent in Ohio to 83 per cent in Tennessee. Of these calcified lesions only from 10 to 50 per cent were explainable on the basis of tuberculin sensitivity. Twenty-four to 45 per cent of the children showed pulmonary calcification without tuberculin allergy.

The observations of Gass and his associates[5] on the development of pulmonary calcification while the children were under observation, and its occurrence without showing tuberculin sensitivity during that period, is highly significant. It seems incredible that tuberculin sensitivity could develop and disappear in periods as short as two years. This observation offered the first substantial evidence that some infection other than tuberculosis might be the cause of this widespread unexplained calcification.

These observations, considered together with certain known facts regarding the distribution of fatal cases of histoplasmosis, suggest the possible etiologic relationship between nontuberculous benign pulmonary calcifications and a benign form of histoplasmosis. The conclusions depend largely on determination of the specificity of the histoplasmin reaction, for which only indirect evidence has been presented. With antigens derived from fungi, there is a possibility of crossed immunologic response to coccidioidin and an antigen derived from Haplosporangium.

BIOLOGIC WARFARE

Biologic warfare was a potential menace throughout World War II. Biologic warfare is defined as the use of bacteria, fungi, viruses, rickettsias and toxic agents from living organisms to produce death or disease in men, animals or plants. Between World War I and World War II many came to believe that this type of warfare was possible. Late in 1941 the National Academy of Sciences was requested to survey the current situation and future possibilities. Following a period of development, under the administration of War Research Service, the main responsibility for the program was carried by the Chemical Warfare Service of the Army; at the peak nearly 3,900 persons were devoted to this work, including nearly 1,000 Navy personnel and nearly 100 civilians. The parent installation was Camp Detrick, at Frederick, Md., and there were other facilities in Mississippi, Indiana and Utah.

As a result of these efforts adequate defenses against a potentially dangerous method of warfare were devised, and the possibility of surprise was forestalled. Apart from the military objectives much information of great value for human welfare was obtained. Unique facilities were established for research and experimentation on pathogenic agents on a scale never before possible.

Of the more important accomplishments of especial medical interest were (*a*) development of methods for the rapid and accurate detection of minute quantities of disease producing agents, (*b*) significant contributions to knowledge of the control of airborne disease producing agents, (*c*) production and isolation, for the first time, of a crystalline bacterial toxin, which has opened the way for the preparation of a more highly purified immunizing toxoid, (*d*) development and production of an effective toxoid in sufficient quantities to protect large scale operations should this be necessary, (*e*) significant contributions to knowledge concerning the development of immunity in human beings and animals against certain infectious diseases and (*f*) important advances in the treatment of certain infectious diseases of human beings and animals, and in the development of effective protective clothing and equipment. Steps are being taken to permit the release of such technical papers and reports as may be published without endangering the national security.

Unlike the development of the atomic bomb and other secret weapons during the war, the development of agents for biologic warfare is possible in many countries, large and small, without vast expenditures of money or the construction of huge production facilities. Preparations for biologic warfare could proceed in many countries, perhaps under the guise of legitimate medical or bacteriologic research. For these reasons, supported by the fact that both Germany and Japan are known to have been engaged in activities looking toward biologic warfare, it seems imperative to continue investigations in this field on a scale sufficient to provide an adequate defense. Moreover, new benefits to medicine may be anticipated.

THE OFFICE OF CORONER

The dubious distinction of having created the institution of the coroner is oftenest accredited to Alfred, surnamed The Great, king of the West Saxons. The original coroner watched for the emoluments accruing to the crown in peculiar circumstances; he inquired into wrecks at sea and secured the flotsam to England, looked into all treasure trove and investigated unusual deaths that the exchequer might not be deprived of the forfeiture of felons. The office of coroner was therefore that of a scavenger; unfortunately an occasional coroner today seems to function in a similar manner.

Sixty-nine years ago the legislature of the state of Massachusetts abolished the office of coroner and substituted a system of medical examiners. The legislative act was prompted by public outcries following inefficient investigation of a peculiarly atrocious crime. In 1915, after prolonged investigation by the commissioner of accounts, the city of New York also abolished the coroner's system and adopted that of the medical examiner. The county of Essex in New Jersey followed.

Wherever the coroner exists in this country his privileges are exceedingly elastic. He may issue subpenas, empanel juries and administer the oath to jurors in order to prosecute inquiry into sudden, violent or suspicious death, no matter how staggering the attendant technical problems may be. He may make or direct postmortem examinations, conduct or institute chemical, bacteriologic and microscopic investigations and, in short, perform the offices of a pathologist. The extent to which the city of New York had previously made provision for the fulfilment of the scientific and quasi-judicial duties of the coroner is indicated by the fact that the post was occupied at various times by a bricklayer, a shoemaker, a carpenter, a stone mason, a plumber, a butcher and an undertaker. The medical responsibilities of the office were delegated to physicians distinguished, with a solitary exception, by political preferment rather than by scientific ability.

The successful conduct of the medical examiner's office is not necessarily limited to thickly populated districts. In the vast territorial expanse covered by the Royal Mounted Police the office of medical examiner, fashioned after the New York City system, functions admirably. In most parts of the United States the office of the coroner continues to exist. Is it not time that our governments modernized their procedures by eliminating this ancient and far too often dishonorable office?

INCOME TAX CREDIT FOR CHARITY PRACTICE OF PHYSICIANS

The value of the services rendered annually by physicians of this country in the treatment of the indigent sick for which they receive no compensation has been estimated as in excess of $300,000,000. Recognition of this tremendous contribution made by physicians for the public good is reflected in a bill, H. R. 5296, introduced in the Congress January 30 by Representative Clare Boothe Luce of Connecticut. The measure provides that physicians, surgeons and dentists, commencing with the taxable year 1946, shall be allowed an additional credit as a deduction on their income tax equal in terms of percentages to that portion of their time each year which is devoted to charity, free clinic work and public research work. The Commissioner of Internal Revenue will prescribe by regulation, it is contemplated, the method of computing such time and the proof which shall be required in substantiation.

At the time the bill was introduced, Representative Luce had inserted in the *Congressional Record* a statement embodying the justification for her sponsorship of this legislation. In connection with the many proposals being made for various kinds of governmental control of medicine, she said:

> None of these proposals is a logical development of the American system of recognizing, promoting and rewarding individual choice and achievement. In our earlier history pioneer medicos were rewarded for their frequently ill paid devotion by a very special place in the community, high respect from their fellow citizens and patients, and payment in lovingly prepared delicacies where cash was scarce. Those times have largely vanished. To become a doctor, a surgeon, a dentist now requires some eight or nine years of unremunerative and expensive schooling. Until he has completed all this, usually by the time he is 29 or 30, the doctor cannot even begin to earn his own bread and salt, much less begin to repay himself for the costs of learning his profession.

After referring to the fact that all reputable physicians give a considerable portion of their time to the treatment of patients who are unable to pay for the services in any way except by gratitude, the statement continues:

> Surveys as to the amount of these unpaid services indicate that the percentages range from around 30 to 45 of all treatments given. This is a direct contribution on the part of the physician, surgeon or dentist to the public welfare. In addition are the hours spent without pay in public research work, on hospital boards and on boards of charitable organizations. All this must be chalked up to professional devotion, since it results in no return and often requires the practitioner to lengthen his working day to fifteen or sixteen hours or more in times of epidemic. There are no limits possible on a doctor's working day.

Because of the facts so well set forth in her statement, Representative Luce believes that the recognition contemplated by her bill is fully justified. This measure is pending before the House Committee on Ways and Means, where, it may be assumed, it will be given consideration by the committee in connection with its program to revise the income tax law.

Current Comment

COMBINED FEVER-PENICILLIN THERAPY

In 1944 Eagle and his associates[1] of Johns Hopkins Hospital showed that the spirocheticidal action of penicillin increases with the temperature in the range 8-40 C. Using five different strains of spirochetes, they found that the percentage of organisms surviving after twenty-four hours at 8, 22-23, 32-33, 36-37 and 39-40 C. was 100, 10, 1, 0.2 and 0.02 respectively. These results were independent of the concentration of penicillin in the range 0.25 to 250 units per cubic centimeter. In their opinion the difference between the results obtained at 37 C. and at 40 C. is sufficiently great to suggest the use of artificially induced fever in conjunction with penicillin in the treatment of syphilis. They believed that such a combined therapy might make it possible to reduce the total dosage, shorten the duration of treatment or do both. Similar effects of hyperthermia on the bactericidal action of penicillin were subsequently reported by Lee and Foley[2] of the Wallace Laboratories, New Brunswick, N. J. In a typical experiment they showed that at 37 C. 1.5 units of penicillin per cubic centimeter of rabbit serum reduced the viable percentage of Staphylococcus aureus 75 per cent by the end of four hours. At 39 C. the viable count was reduced by 83 per cent and at 42 C. by 96 per cent. In control tests without penicillin there was as much as a four hundredfold increase in the bacterial count by the end of the same period. While Lee does not formally recommend combined fever and penicillin therapy in staphylococcic infections, such a combination would be a logical application of his data.

COOPERATIVE STUDIES ON THIOURACIL

Elsewhere in The Journal (pages 315 and 343) are two clinical communications on the results of cooperative studies on the toxicity of thiouracil, a new drug for the treatment of thyrotoxicosis. The studies should clearly define the toxicity of this drug, which is now available in interstate commerce. Only by careful use can thiouracil be expected to serve beneficially in modern chemotherapy. Moore's report offers the joint experience of eleven clinics in the United States and one in England; it is not intended as an appraisal of the usefulness of thiouracil. The statement by Van Winkle and his associates is the result of information gathered by questionnaire by six drug manufacturers interested in the distribution of thiouracil. This statement has been submitted as a report to the Council on Pharmacy and Chemistry and presents a new and commendable peak in cooperation. Both papers are excellent examples of the value of pooling information and should serve as guides for the future when other new drugs appear on the medical horizon under a cloud of uncertainty.

MEDICINE AND THE WAR

ARMY

GENERAL KIRK AWARDS FIVE OFFICERS LEGION OF MERIT

Five Legion of Merit Awards were recently presented by Major Gen. Norman T. Kirk, Surgeon General of the Army, to Col. James E. Ash, director of the Army Medical Museum; Lieut. Col. Fred J. Fielding, chief of Classification of Records Section, Military Personnel Division; Lieut. Col. Michael E. DeBakey, chief of General Surgery Branch, Surgical Consultants Division; Lieut. Col. Oliver R. McCoy, director of Tropical Disease Control Division, Preventive Medicine Service, and Major Robert L. Kaye, Corps of Engineers, commanding officer of Cinchona Research Unit.

As director of the Army Medical Museum, the citation stated, Colonel Ash "organized the most extensive tissue pathology service ever known to the world. The photographic and art service of the museum was developed, which amassed a wealth of visual material—over 40,000 black and white photographs, over 4,000 kodachromes, and over 50,000 feet of colored movies."

Lieutenant Colonel Fielding "effected the assignment and equitable distribution of medical skills. Under his guidance the entire personnel records system was coordinated and integrated to the end that available professional abilities were utilized to the maximum degree."

Lieutenant Colonel DeBakey "conceived and initiated the monthly *Bulletin of the United States Army Medical Department,* which furnished physicians all over the world with authoritative information on advances in medicine.

In the field of malaria treatment and control Lieutenant Colonel McCoy "fostered activity in the dissemination of knowledge pertinent to tropical disease control, both in professional circles and among troops," thus maintaining their health while operating in overseas areas. His "outstanding achievements in bringing into being a means of production of quinine and related antimalarials signify a magnificent contribution to mankind."

AWARDED DISTINGUISHED SERVICE MEDAL

Col. Tracy S. Voorhees, formerly a New York attorney and president of the Long Island College Hospital, Brooklyn, was recently awarded the Distinguished Service Medal for outstanding accomplishment while serving in the Office of the Surgeon General as director of the legal division and later as director of the control division. Colonel Voorhees is now on duty as assistant to the Secretary of War in the handling of matters affecting the medical department, with particular reference to the care of the sick and wounded and the demobilization of medical personnel.

HEALTH OF SOLDIERS IN PACIFIC AREAS REPORTED GOOD

Brig. Gen. Raymond W. Bliss, Deputy Surgeon General of the Army, in a report of his recent tour of Pacific theaters, stated that American soldiers in the Pacific are an exceptionally healthy body of troops despite the fact that many of them are located in the most disease ridden areas in the world.

The low disease rate among American forces in those areas is the result of the program of preventive medicine, involving the expenditure of millions of dollars, which the Surgeon General's Office inaugurated to guard the welfare of this country's fighting forces. To accomplish these results the Army Medical Department took the initiative in organizing an all out attack against disease. The cooperation of the best civilian and military tropical medicine experts in the country was enlisted, special courses were organized to teach army doctors how to care for troops exposed to these strange diseases, and a campaign of education in hygiene and field sanitation was inaugurated among the soldiers. Protective clothing, new repellents and insecticides, including DDT and drugs such as atabrine, penicillin and the sulfonamides, all played a part in this effective program.

The purpose of the trip was the study of medical service in the Pacific, demobilization of medical department personnel and the adoption of plans for the permanent hospitalization and evacuation of the army of occupation.

APPOINTED PLASTIC SURGERY CONSULTANT

Col. James B. Brown, chief of plastic surgery at Valley Forge General Hospital, Phoenixville, Pa., was recently appointed senior consultant in plastic surgery to the Surgeon General.

ARMY AWARDS AND COMMENDATIONS

Lieutenant Colonel Franklin C. McLean

Lieut. Col. Franklin C. McLean, now professor of pathologic physiology at the University of Chicago, who served during the war in the Chemical Warfare Service of the United States Army, was recently awarded the Legion of Merit. Dr. McLean, who was director of toxicology for the Chemical Warfare Service from October 1943 to March 1944, received the citation for his demonstration of remarkable talents and scientific versatility in laboratory and field testing and in improving the effectiveness of persistent blister and other gases. In addition to his work at Edgewood Arsenal Dr. McLean was chief of the Persistent Section of the San Jose Project in Panama. The citation was conferred also for his work as a member of the British-American coordination staff from June 1944 to September 1945, in which he was a factor in evaluating the biologic aspects of all research and testing of gas warfare equipment performed by the United States and the British commonwealth. Previous to receiving his commission as lieutenant colonel Dr. McLean was director of the toxicity laboratory of the University of Chicago and resumed his duties there as professor of pathologic physiology on Oct. 1, 1945.

Lieutenant Colonel Morton H. Flaherty

The Army Commendation Ribbon was recently awarded to Lieut. Col. Morton H. Flaherty, White Plains, N. Y., for meritorious service as assistant to the surgeon and as surgeon, Eastern Defense Command, with Headquarters at Governors Island, N. Y., from Jan. 8, 1943 to Dec. 31, 1945. "Through his experience, professional ability, keen analytical mind and conscientious effort," says the citation, "he was of very material assistance in the maintenance of adequate hospitalization and medical service for units of this command. He is to be particularly commended for his efforts in maintaining an exceptionally low rate for contagious diseases in this command in spite of rigorous climatic conditions and isolated facilities." Dr. Flaherty graduated from Columbia University College of Physicians and Surgeons, New York, in 1935 and entered the service May 15, 1941.

Major William Clinton Calvert

The Soldier's Medal was recently awarded to Major William C. Calvert, West Orange, N. J., "for heroism near Antwerp, Belgium, on Feb. 23, 1945. When a flying bomb landed in a village near his headquarters Major Calvert with three enlisted men immediately went to the scene to administer medical aid. On arriving they discovered that a child was trapped in the wreckage of a house Completely disregarding his own safety, Major Calvert crawled into the cellar despite the danger from an overhanging mass of cement and steadily rising water from a broken main and held the child's head above water for nearly three hours until she could be removed to safety Major Calvert's coolness, courage and devotion to duty reflect the highest credit on himself and the Army of the United States" Dr Calvert graduated from New York Medical College, Flower and Fifth Avenue Hospitals, New York, in 1929 and entered the service July 18, 1942

Captain William S M. Ling

An Oak Leaf Cluster to the Bronze Star was recently awarded to Capt William S M Ling, New York, "for meritorious achievement in connection with military operations in Italy from Jan 15 to April 9, 1944 As battalion surgeon of the 751st Tank Battalion Captain Ling displayed outstanding courage and exceptional professional ability during the preparation, the actual landing and subsequent action of the battalion at the Anzio beachhead Owing to the special situation it was necessary for men to remain in their tanks for days at a time and without relief This made it very difficult on crewmen, and many of the men began to complain of claustrophobia, or that the tanks seemed to be closing in on them It was due to Captain Ling's personal attention to these men that many of them remained on duty and were not sent back to rear areas as battlefield exhaustion cases He was untiring in his efforts and demonstrated a vast knowledge of his medical profession in fearlessly proceeding under intense fire to treat men who had been wounded and needed his care" Dr Ling graduated from the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, in 1940 and entered the service Sept 1, 1941

Captain Robert Boyd Stith

The Bronze Star was recently awarded to Capt Robert Stith of Florence, S C, for meritorious services in support of combat operations from Nov 9, 1942 to May 2, 1945 in North Africa and Italy "As assistant chief of the medical division in an evacuation hospital," reads the citation, "Captain Stith rendered outstanding service of the skilled care and treatment of thousands of patients working under severe conditions of weather and enemy action By his diligent performance he provided a constant inspiration and example to the officers, nurses and men working under him In charge of the preoperative ward on the Anzio beachhead, Captain Stith calmly and skilfully performed his duties during periods of enemy shell fire and by his conduct influenced attainments, persevering efforts and devotion to duty Captain Stith contributed immeasurably to the success of his unit's medical mission" Dr Stith graduated from Duke University School of Medicine in 1935 and entered the service April 15, 1942

Lieutenant Colonel Weldon J. Walker

Lieut Col Weldon J Walker, formerly of Los Angeles, was recently awarded the Bronze Star "for meritorious service in connection with military operations against the enemy in Germany between April 3, 1945 and May 8, 1945 Lieutenant Colonel Walker, commanding officer, exerted constant and untiring effort to render superior medical service to units of the 3d Corps Dangerous reconnaissances made personally, at a time when the front lines were in a fluid condition, enabled him to maintain liaison with these supported organizations His initiative, diligence, sense of responsibility and considered judgment reflect credit on himself and the Army" Dr Walker graduated from the College of Medical Evangelists, Los Angeles, in 1940 and entered the service July 12, 1941

NAVY

BIOLOGIC WARFARE STUDIED BY THE NAVY

For two and a half years a Navy project was secretly undertaken at the University of California, Berkeley, of joint Army Navy and civilian cooperative research in the field of biologic warfare, which was not announced until recently by the Navy Department The group was composed of twelve officers and nine enlisted men when the project was undertaken in April 1943 under the command of Capt Albert Paul Krueger (MC), U S N R, but increased to nineteen officers and forty-five men by VJ day

Much must still remain untold, but after thirty-three months of hazardous and painstaking study it may now be revealed that

1 Considerable knowledge has been gained in mass defense against possible enemy employment of a certain disease which is highly fatal

2 Laboratory and field data have been gathered which demonstrate that a man-made epidemic as an instrument of war is a likely possibility

3 A protective suit, with self-contained oxygen supply, has been devised for the use of workers in any prospective rescue or decontamination operation

4 Conclusive information has been obtained which would be of great value not only for protection from bacterial attack but for control of communicable airborne diseases among a peacetime population

The disease in question, the identity of which must still be withheld, is centuries old, it is said, and one of the greatest of killers Captain Krueger stated that the "program was undertaken not from the standpoint of academic research but with a view of obtaining short term practical results with regard to offensive possibilities and defensive countermeasures"

The precautionary measures taken during the study were so efficient that no infections due to the organisms studied occurred among the investigators The work of this group, known as Naval Medical Research Unit No 1, is continuing, coordinated by the Bureau of Medicine and Surgery with the Army Navy biologic warfare program

VICE ADMIRAL McINTIRE AWARDED DISTINGUISHED SERVICE MEDAL

The Distinguished Service Medal was recently awarded to Vice Admiral Ross T McIntire, Chief of the Bureau of Medicine and Surgery since Dec 1, 1938 and Surgeon General of the Navy He was cited for his extraordinary ability in planning and applying the medical program for the Navy and Marine Corps, the citation emphasizing his "exceptionally meritorious service to the government of the United States in a duty of great responsibility as chief of the Bureau of Medicine and Surgery and Surgeon General of the Navy from Dec 7, 1941 to Aug 31, 1945 Displaying extraordinary foresight, unerring judgment and great administrative ability, Vice Admiral McIntire directed the planning and the practical application of the vast program which provided medical care and supply for the Navy and the Marine Corps on a scale and with a degree of success unprecedented in naval warfare His outstanding achievement had a direct and vital part in the successful prosecution of the war' Vice Admiral McIntire has also received decorations from Belgium, Brazil, Denmark France, French Morocco Luxembourg Nicaragua Norway, Poland and Sweden

NAVY AWARDS AND COMMENDATIONS

Commander Murray W Ballenger

Comdr Murray W Ballenger Medical Department, Naval Air Station, Pensacola, Fla, was recently awarded the Bronze Star The award was made for his efforts following damage to his ship which resulted in a number of casualties He worked tirelessly for many hours treating the wounded "By his high professional skill,' the citation reads, 'he undoubtedly saved many lives His outstanding conduct throughout has distinguished him among those performing duties of the same character Dr Ballenger graduated from the University of Kansas School of Medicine, Kansas City, in 1935 and entered the service Jan 11, 1937.

Lieutenant Commander Howard Owen Smith

Lieut. Comdr. Howard Owen Smith, formerly of Marlin, Texas, was recently commended "for meritorious service in the line of his profession as a gastrointestinal and general surgeon aboard a United States Navy hospital ship from August 1944 to May 1945. During this period Lieutenant Commander Smith displayed unusual zeal in his devotion to duty and exhibited physical endurance and fortitude to an inspiring degree. His outstanding skill, knowledge and ability were materially responsible for the alleviation of pain and suffering and were instrumental in saving the lives of many men who otherwise would have died of shock or other disabling conditions. His conduct throughout was in keeping with the highest traditions of the United States Naval Service." Dr. Smith graduated from the University of Texas Medical Branch, Galveston, in 1922 and entered the service Nov. 26, 1942.

Captain Millard F. Hudson

A Letter of Commendation was recently presented to Capt. Millard F. Hudson, formerly of San Pedro, Calif., "for meritorious service as Atlantic Fleet Medical Officer on the staff of Commander Service Force, Atlantic Fleet, from June 1942 until November 1945." The citation accompanying the award stated that "Captain Hudson administered the medical affairs of the Atlantic Fleet and fulfilled the multitudinous responsibilities of his assignment with outstanding efficiency and skill. He directed and detailed assignments of all Hospital Corps enlisted personnel to the forces afloat and at outlying bases. By personal consultation, by visitation and by the preparation of many technical bulletins he materially contributed to the operational readiness of all fleet medical units to meet demands of battle. Captain Hudson's professional skill and outstanding performance of duty in a position of great responsibility reflect great credit on himself and the United States Naval Service." Dr. Hudson graduated from Vanderbilt University School of Medicine, Nashville, Tenn., in 1917 and entered the service Dec. 29, 1917.

Commodore Morton D. Willcutts

For his services as fleet medical officer on the staff of Commander, Fifth Fleet, Commodore Morton D. Willcutts, formerly of New York, was awarded the Legion of Merit. The citation accompanying the award stated that it was given "for exceptionally meritorious conduct in the performance of outstanding service as fleet medical officer on the staff of Commander, Fifth Fleet, from April to November 1945. During this period he participated in the amphibious operations to capture and occupy Okinawa and in the occupation of Japan. Commodore Willcutts with great diligence applied himself to the solution of medical problems incident to fleet operations, the handling of casualties and the health of personnel taking part. His sound judgment and excellent vision contributed to the success of these operations. When the fleet flagship was hit by a suicide plane with a bomb on May 12, with heavy casualties resulting, he took charge of the wounded on the main deck in the absence of the ship's medical officers, who were below at their battle stations. His promptness, presence of mind and professional skill were of great value on this occasion. His conduct was at all times in keeping with the highest traditions of the United States Naval Service." Dr. Willcutts graduated from the Indiana University School of Medicine, Indianapolis, in 1916 and entered the service Sept. 4, 1917.

MISCELLANEOUS

SELECTIVE SERVICE MEDAL

A letter addressed to The Journal *by Dr. E. D. Skeen of Gary, Ind., called attention to the fact that many members of draft boards from Gary have been called to Indianapolis to receive from the state director of Selective Service a certificate and a medal indicating their contribution but that the list published did not include the names of any physicians. A letter was addressed to Major Gen. Lewis B. Hershey, director of the Selective Service System, whose reply follows:*

Dear Doctor Fishbein:—I have received your letter dated Jan. 24, 1946, in which you quote a statement you have received from one of your subscribers in regard to the award of the Selective Service Medal to local board examining dentists and physicians.

Public Law 112, 79th Congress, approved July 2, 1945, provides that the Selective Service Medal and Certificate may be awarded to members of local boards, members of appeal boards, government appeal agents, local board examining dentists and physicians, members of medical advisory boards and reemployment committeemen who have completed more than two years of loyal and faithful service and to such others as may be selected by the director of Selective Service.

Under the procedure for the award of the medal, local board members, appeal board members and government appeal agents must be recommended by the state director of Selective Service. Other persons eligible for the award, including local board examining physicians, must be recommended by the appropriate local board and the state director.

Owing to production difficulties, it has not been possible to obtain sufficient medals, presentation boxes and certificates of merit to make the award to all eligible persons at the same time. For that reason the first awards are being made to local board members, appeal board members and government appeal agents.

In certain of the states the lists of eligible persons who are to be recommended by the local boards were not received in sufficient time to complete the printing of names on certificates. Approximately 35,000 certificates are in the process of printing at the present time. As soon as a sufficient supply of medals and certificates is received from the contractors, the awards will be made to all qualified persons.

The examining dentists and physicians who so patriotically served our local boards will not be ignored. It is merely a question of obtaining the medals and certificates for presentation. It is hoped that we will have the medals and certificates to make the awards during the latter part of February or the first of March.

Lewis B. Hershey, *Director,*
Washington, D. C.

OFFICERS RELEASED FROM U. S. PUBLIC HEALTH SERVICE

A letter from Surgeon General Thomas Parran reveals that there were at the end of hostilities approximately 1,050 reserve medical officers on active duty with the United States Public Health Service. About 275 of these officers have been released to date. The releases are being made in accordance with a point system previously published in The Journal. Officers with 45 or more points are being released during the months of January and February. Surgeon General Parran states that it is expected that the critical score will be reduced on March 1 but that it is not possible at this time to state the extent of the reduction.

DISABLED PERSONS ASSOCIATION OF AMERICA

The Disabled Persons Association of America, Chicago, a nonpartisan and nonsectarian association, incorporated not for profit, recently announced an exclusive free selective placement service for disabled veterans. The Veterans Division has office and factory jobs available for disabled veterans, as well as some out of town jobs. Full cooperation with any and all veterans' organizations and other agencies will be given, and a request is made to the public to refer any disabled veterans in need of employment or counsel to Capt. A. L. Myers any day of the week between the hours of 9 a. m. and 1 p. m. at suite 1408, 39 South State Street, Chicago.

PHYSICIANS SEPARATED FROM SERVICE

ARMY MEDICAL CORPS OFFICERS RECOMMENDED FOR/OR RELIEVED FROM ACTIVE DUTY

Alabama

Anderson, William O., Capt., Halcyville.
Bradford, Duke C., Col., 3121 12th Ave. N., Birmingham.
Britt, Walter S., Capt., 220 Cherry St., Eufaula.
Bryant, Henry C., Capt., 431 12th Terrace N., Birmingham.
Cobb, John M., Lt. Col., Tuskegee.
Darden, William H., Lt. Col., 2112 Noble St., Anniston.
Kendrick, James E. Jr, Lt. Col., 310 S. Park St., Greenville.
Martin, Carl T., Capt., Abbeville.
Mason, Robert E., Capt., 3802 Cliff Rd., Birmingham.
Monsky, David B., Major, 111 Ponce de Leon, Montgomery.
Motley, Jewett P., Capt., 2746 20th St., Ensley.
Parker, Paul H., Major, Margaret.
Peters, Jesse J., Major, Veterans Adm., Tuskegee.
Rowe, Mason C. Jr., Capt., 1203 Catalpa St., Dothan.
Samples, Leon D. Jr., 1st Lt., 425 12th Ave. N., Birmingham.
Shiffman, Hans P., Capt., DMD, SH, Napier Fld., Dothan.
Sparks, Thomas P., Capt., Box 325, Sylacauga.
Treherne, Alfred J., Lt. Col., Box 398, Atmore.

Arkansas

Binns, Byron Z., Major, Monticello.
Crocker, Elvis W., Capt., 1103 Porter St., Helena.
Crow, Marvin B., Capt., Warren.
Dew, Hogan A. Jr., Capt., Hamburg.
Fowler, Hollace D., Major, 412 Rosette, Little Rock.
Gaston, Cecil L. Jr., Major, Trinity Hosp., Little Rock.
Hundley, Louis K., Major, P. O. Box 439, Fayetteville.
Johnston, W. W., Major, Phillips City Health Unit, Helena.
Kay, Royal H., Capt., Cotton Belt Hosp., Texarkana.
Kirkham, Dunham, Major, 220 W. 20th St., Little Rock.
Lutterloh, Charles H., Lt. Col., 29 Circle Dr., Hot Springs.
McLain, Monroe D., Major, 909 Main St., Little Rock.
Maddox, Alfred H., Major, Elaine.
Moulton, Everett C. Jr., Capt., 935 Adelaide Ave., Fort Smith.
Phipps, W. E., Capt., 401 Ridgeroad, Pk. Hill, N. Little Rock.
Ritchie, Elmer J., Major, 621 W. 4th St., North Little Rock.
Savage, Hugh W., Major, 317 Beach St., Little Rock.
Thompson, Albert W., 1st Lt., Bentonville.
Williams, Jacob M., Capt., Monette.

Colorado

Alexander, Harry A., Major, 750 Cascade Ave., Boulder.
Barber, Edgar W., Lt. Col., 227 16th St., Denver.
Beck, Harold J., Major, 615 W. 22d St., Pueblo.
Benell, Otto E., Major, 1700 13th Ave., Greeley.
Benov, Harry, Capt., 1101 Colorado Blvd., Denver.
Emery, George D., Capt., 672 Cherry St., Denver.
Girod, Frank P., 1st Lt., Cortez.
Hill, Kenneth A., Lt. Col., 335 S. Vine St., Denver.
Karlick, Joseph R., Capt., 1936 Pearl, Denver.
McGraw, John P., Lt. Col., Box 308, Estes Park.
Peterson, Arthur E., Capt., 1905 19th Ave., Greeley.
Pingrey, Fergus R., Capt., 1801 Main Ave., Durango.
Pollice, John A., Major, 4344 Bryant St., Denver.
Porter, Whitney C., Major, 4310 E. 25th Ave., Denver.
Robinson, George L., Capt., Salida.
Rounds, Roy C., Major, 1427 Franklin St., Denver.
Ruzicka, Lawrence J., Capt., 1120 S. Broadway, Denver.
Sawyer, Kenneth C., Major, 1819 Gilpin St., Denver.
Shaw, Dwight B., Lt. Col., 702 N. Main, Pueblo.
Shrout, Cecil B., Col., Vet. Adm., Ft. Lyon.
Shumsky, Nathan S., Capt., 2058 Ivanhoe St., Denver.
Spillane, John H. Jr., Major, 30 E. Platte, Colorado Springs.
Whitehouse, Alfred E. Jr., Capt., 700 E. Aspen, Fruita.

District of Columbia

Beard, William H., Lt. Col., 2814 Connecticut Ave., Washington.
Beardsley, L. G., Col., 2650 Wisconsin Ave. N.W., Washington.
Daue, Edwin O. Jr., 1st Lt., 1129 Fern St. N.W., Washington.
Friedman, J. M., Lt. Col., 3539 Holmead Pl. N.W., Washington.
Gibson, Frank E. Jr., Major, 927 Eye St., N.W., Washington.
Gladsden, Eugene S., Major, 922 C St. S.E., Washington.
Greene, Joseph L., Capt., 2518 Tunlaw Rd. N.W., Washington.
Jeffrey, Millard, Capt., 2800 Woodley Rd. N.W., Washington.
Lyons, John H., Col. 1644 21st St., N.W., Washington.
Meisenbach, A. E. Jr., Capt., 927 17th St., N.W., Washington.
Randall, Robert S., Capt., 1944 3d St. N.W., Washington.
Ratcliffe, Harold E., Major, St. Elizabeth's Hosp., Washington.
Pekin, Thomas J., Lt. Col., 2650 Wisconsin Ave., Washington.
Reeves, G. W., Capt., 2916 New Mexico N.W., Washington.
Sterling, Harold, 1st Lt., 4102 14th St. N.W., Washington.
Sugar, Samuel J., Major, Gallinger Mun. Hosp., Washington.

Florida

Annis, Leonard S., Lt. Col., Bayshore Royal Hotel, Tampa.
Baker, Archie J., Capt., 4035 N. Alhambra Dr., Jacksonville.
Ball, William H., Major, 1005 Morrison Ave., Tampa.
Barks, Orville L., Capt., Groveland.
Edwards, Joshua L., Capt., 806 W. Duval St., Lake City.
Fox, Edward F., Major, 404 Ingraham Bldg., Miami.
Helms, John S. Jr., Lt. Col., 3314 Lykes Ave., Tampa.
Hyman, Jack, 1st Lt., 6110 Interbay Blvd., Tampa.
Morton, Henry G., Capt., 1074 S. Citrus Ave., Sarasota.
O'Donnell, William G., Capt., 712 SW 7th St., Miami.
Overstreet, Ralph M. Jr., Capt., Jackson Mem. Hosp, Miami.
Palmer, George S., 1st Lt., Box 547, Tallahassee.
Parker, Martle F., Capt., Lisenby Hosp., Panama City.
Parks, Lorenzo L., Lt. Col., State Bd. of Health, Jacksonville.
Parsons, Hugh E., Capt., 512 Maas Office Bldg., Tampa.
Ralston, Raymond H., Major, 523 E. McDonald St., Lakeland.
Sigman, Murray D., Capt., 36 Rhode Ave., St. Augustine.
Stebbins, Alvin L., Major, 803 N. Palafox St., Pensacola.

Georgia

Abram, Lewis E., Major, 816 S. Lee, Fitzgerald.
Alsup, William B. Jr., Capt., University Hosp., Augusta.
Anderson, William H. Jr., Capt., Grady Hosp., Atlanta.
Armstrong, William B., Capt., 4270 Harris Trail, Atlanta.
Bailey, Thomas E., Capt., 1833 Starnes St., Augusta.
Berry, Robert L., Capt., Villa Rica.
Cary, Howard R., Major, Milledgeville.
Evans, Albert L., Capt., 518 Park Dr., N.E., Atlanta.
Golsan, Willard R., Lt. Col., 8A Massee Apts., Macon.
Harper, Sage, Major, Wray.
Hilsman, Joe H. Jr., Capt., 72 11th St., NE, Atlanta.
Hoffman, Byron J., Capt., 768 Juniper St. N.E., Atlanta.
Huskey, Aubrey L., Major, 703 Med. Arts Bldg., Atlanta.
Ketchum, Clarence W., Major, Grady Hospital, Atlanta.
Little, Gwynne H., Capt., 119 King St., Dalton.
Litton, James H., Lt. Col., Court House, Milledgeville.
McMillan, Carl B., Major, 3996 N. Ivy Rd., Atlanta.
Martin, Walter D., Capt., PO Box 219, Shellman.
Muse, Jesse P., 1st Lt., 740 Seiler Ave., Savannah.
Niles, George A. Jr., Capt., Grady Hosp., Atlanta.
Pomeroy, William L., Major, 1421 St. Mary's Dr., Waycross.
Powers, Leander K., Capt., Guyton.
Rich, Maurice, Capt., 938 Oakdale Rd., Atlanta.
Rubin, Jacob, Capt., 910 E. 35th St., Savannah.
Schaffer, William B., Lt. Col., Box 366, Toccoa.
Smith, Charles R., Capt., Terrell Co. Health Dept., Dawson.
Sturm, R. T., 1st Lt., 1302 W. Peachtree, Apt. 108, Atlanta.
Tighe, Leo R., Major, Vet. Adm. Facility, Augusta.
Weinberg, James I., Lt. Col., 949 Courtney Dr., NE, Atlanta.

Maine

Branson, Sidney R., Capt., Main St., South Windham.
Clapperton, Gilbert, Major, 20 Ware St., Lewiston.
Colley, Maynard B., Major, Wilton.
Comeau, Wilfred J., Lt. Col., 48 Penobscot St., Bangor.
Cox, William V., Lt. Col., 82 Gamage Ave., Auburn.
Dougherty, John F., Capt., 60 North St., Bath.
Eastman, Charles W., Major. 15 Millet St., Livermore Falls.
Feeley, John R., Capt., 3 3d St., Bangor.
Finks, Henry, Major, 286 State St., Portland.
Laney, Richard P., Major, Prospect St., Skowhegan.
Lenfest, Stanley R., Capt., Waldoboro.
Lombard, Reginald T., Lt. Col., 793 Main St., South Portland.
McManamy, Eugene P., Capt., Cottage Lane, Cape Cottage.
Metzgar, John G., Capt., 31 Grove St., Augusta.
Moore, Roland B., Col., RFD 3, Portland.
Morrison, Alvin A., Major, 165 Glenwood Ave., Portland.
Moulton, Albert W. Jr., Capt., 180 State St., Portland.
Richards, Carl E., Major, Box 81, Alfred.
Webber, Wedgwood P., Major, 376 Main St., Lewiston.

Mississippi

Cohen, Emanuel, Capt., Pace.
Holley, Robert L. Jr., Capt., U. of Miss. Hosp., University.
House, Nathaniel C., Major, Belzoni.
Hudgens, John C., Lt. Col., Vet. Adm. Facility, Gulfport.
Minter, David R., Lt. Col., Rochdale.
Sims, Murphy M., Capt., Health Unit, Oxford.
Sneed, Ralph, Major, Charity Hosp., Jackson.
Wiener, William B., Capt., Canton.
Wright, Frederick L., Lt. Col., Gulfport.

Choice, Robert W., Capt., Wakita.
Foerster, H. A., Lt. Col., 806 NW 25th St., Oklahoma City.
Fox, Raymond H., Lt. Col., 915 N. Main St., Altus.
Greenberger, Edward D., Capt., 216 E. Choctaw, McAlester.
Harrison, S. P., Capt., 1701 NW 31st St., Oklahoma City.
Hendren, Walter S. Jr., Capt., 501 N.W. 12th, Oklahoma City.
Henry, Millard L., Capt., Heavener.
Hubbard, John R., Lt. Col., 1628 N.E. 11th, Oklahoma City.
Hubbard, William E., Capt., 1500 N.E. Park Pl., Oklahoma City.
Lively, Claude E., Major, 1275 S. 6th St., McAlester.
Maril, Joseph J., Major, 816 Bell Ave., Lawton.
Neilson, William P., Lt. Col., 3200 Lahoma Rd., Enid.
Petty, James S., Major, 521 E. Logan, Guthrie.
Prosser, Moorman P., Major, Cent. Okla. State Hosp., Norman.
Records, John W., Major, 2523 N. Dewey, Oklahoma City.
Reiff, William H., Capt., 500 N.E. 15th, Oklahoma City.
Rutherford, Vester M., Major, Box 75, Woodward.
Scott, George W., Capt., Tishomingo.
Shofstall, William H., Capt., 1445 N. Main St., Tulsa.
Smith, Carlton E., Major, 123 N. 4th St., Henryetta.
Stout, Hugh A., Capt., 809 N. Beard St., Shawnee.
Watson, Isaac N., Lt. Col., 439 E. Ayers, Edmond.
Weaver, William N., Lt. Col., 408 S. 12th St., Muskogee.
Wheeler, Homer C., Capt., Sallisaw.

Oregon

Mac Dougall, Walter H., Capt., Box 304, Lakewood, Oswego.
Morris, David A., Capt., 1225 Mill St., Eugene.
O'Donnell, Richard H., Capt., 3537 S.E. Main, Portland.
Ray, George L., Capt., 808 NE 23 Ave., Portland.
Reed, Robert J., Capt., 3816 N.E. 33d Ave., Portland.
Strohm, John G., Col., 610 S.W. Alder St., Portland.
Warnell, Charles E., Capt., 6109 SE Belmont, Portland.

Rhode Island

Barry, Ambrose G., Capt., 20 Prince St., Pawtucket.
Dunstan, Paul L., Capt., State Hosp. Mental Dis., Howard.
Horvitz, Abraham, Capt., 127 Gallatin St., Providence.
McDonnell, William A., Capt., 88 Jefferson St., Providence.
McIntyre, William A., Capt., 132 Whitford Ave., Providence.
Melvin, Edward G., Major, 57 Albert Ave., Cranston.
Nestor, Thomas A., Major, 710 N. Main St., Providence.
Perry, Thomas Jr., Capt., 46 Pitman St., Providence.
Rogell, Harold I., Lt. Col., 377 Angell St., Providence.

Virginia

Alexander, John E., Major, Vienna Medical Center, Vienna.
Buckley, Michael L., Major, 2507 N. Pershing Dr., Arlington.
Cantor, Hyman, Capt., 17 Wythe St., Petersburg.
Driscoll, William D. R., 1st Lt., 518 Riverside Ave., Covington.
Edwards, Hugh R., Lt. Col., Buxton Hosp., Newport News.
Humphries, Thomas J., Capt., 1141 2d St. S.W., Roanoke.
Jones, Herbert C., Lt. Col., 1638 Westover Ave., Petersburg.
Jones, William R. Jr., Capt., 1004 West Ave., Richmond.
Judson, John H., Capt., 6121 N. 18th St., Arlington.
Kirchner, John A., Capt., Hercules Powder Co., Radford.
Larkum, Newton W., Lt. Col., Box 1384, Charlottesville.
Nalls, Walter L., Lt. Col., 3110 Grove Ave., Richmond.
Phipps, Glenn W., Capt., PO Box 74, Independence.
Pritchett, Drake, Capt., 108 W. Main St., Danville.
Robertson, Rowland H. Jr., Capt., Lewis-Gale Hosp., Roanoke.
Robins, Charles R. Jr., Major, Stuart Circle Hosp., Richmond.
Rowe, Carter R., Major, 1200 Prince Edward, Fredericksburg.
Siersema, Reynold C., Major, 120 Westmoreland, Richmond.
Snider, John D., Capt., Ashburn.
Sproul, Alexander E., Capt., E. Beverly St., Staunton.
Stanley, Robert R., Capt., Charlottesville.
Steinberg, Harry, Major, Box 64, Bastian.
Verdel, Louis F., Col., Vet. Adm., Roanoke.
Wolfe, Frank B., 1st Lt., Coeburn.

Washington

Black, John J., Major, 209 E. 9th, Ellensburg.
Carter, Ronald P., Major, 3216 W. 58th St., Seattle.
Gunderson, Harold J., Capt., 1011 Grand, Everett.
Judd, Herman S. Jr., 1st Lt., West. State Hosp., Ft. Steilacoom.
Kroger, Orville C., Capt., 114 W. Magnolia, Centralia.
Lyons, Clinton G., Major, 6061 7th Ave. N.E., Seattle.
Meyer, William V., Capt., 1006 Colby Ave., Everett.
Nakashima, Victor K., Capt., 1017 Jackson St., Seattle.
Overley, Harold G., Capt., % C. J. Alexander, Prosser.
Petrone, Rosco E., Capt., American Lake.
Proffitt, Josiah C., Lt. Col., 4710 University Ave., Seattle.
Wham, Manley J., Capt., Holden.

Wisconsin

Behnke, C. H., Capt., 8410 Watertown Plank Rd., Wauwatosa.
Bitter, Reuben H., Major, 85 Oakland Ave., Oshkosh.
Dorn, Anton S., Capt., 1535b N. 15th St., Milwaukee.
Dunker, George O., Capt., 2302 E. Beverly Rd., Milwaukee.
Finn, Walton C., Major, 20 Forest Ave., Fond du Lac.

ORGANIZATION SECTION

Washington Letter

(From Our Regular Correspondent)

Feb. 4, 1946.

Opinions of Blue Cross President on National Health Problem

John R. Mannix, national chairman of the Blue Cross Plans for hospitalization, told members of the Blue Cross commission at the quarterly meeting that federal legislation would not be necessary to solve the national health problem. He based this opinion on a current membership of 20 million persons and a weekly enrolment of 100,000 in the organization. The nonprofit group has a membership of 3,500 hospitals. The commission set up a special group to study provision of additional hospital facilities for veterans. Mr. Mannix said that a national health program should permit enrolment of self-employed persons in a hospital plan. Members of the commission besides Mr. Mannix are M. Haskins Coleman, Richmond, Va., vice chairman; George Putnam, Boston, treasurer; Dr. Louis E. Jarrett, New Orleans; Ray F. McCarthy, St. Louis; Dr. Basil C. MacLean, Rochester, N. Y.; E. A. van Steenwyk, Philadelphia; Msgr. R. Marcellus Wagner, Cincinnati; F. A. Wardenburg, Wilmington, and C. Rufus Rorem, Chicago, director of the national organization.

Nurses' Memorial Campaign Gets Off to Good Start

The campaign to raise $2,000,000 to erect a nurses' national memorial in Washington has been launched with considerable success. At a Washington meeting, at which Mrs. Harry S. Truman was guest of honor, $150,000 in initial pledges was obtained. The memorial will take the form of a social center or home for nurses and other women in the armed forces medical corps. Surg. Gen. Norman T. Kirk, principal speaker, paid tribute to the work done by the 57,000 army nurses who served during the war. He mentioned the nurses on the Anzio beachhead who performed their duties within range of enemy fire. He also lauded Capt. Gladys Mealer, chief nurse in the tunnel at Corregidor, and the 55 nurses, the dietitian and the physical therapist who "sweated in the hell of the Santo Tomas internment camp for almost three years with nothing but rice to eat for most of the time and not enough of that." "The real monument to the work of the army nurse is enshrined in the hearts of the men they served so well," he said.

Development of "Cosmetic" Artificial Hand at Walter Reed

Although cautioning against overoptimism, Lieut. Col. Donald B. Slocum, director of the Walter Reed Hospital laboratory, reports that a new type of "cosmetic" hand, which "looks like one and can be used like one," has been developed at the hospital. Progress is reported in the efforts of Major Charles A. Jackson, dental officer, and T/3 C. O. Anderson and others who are utilizing plastics of which dentures are made to develop lifelike hands that can be worn without gloves. A staff of eleven research engineers and highly trained technicians are working on the new "hand" in the Walter Reed laboratory. All seven of the nation's army hospitals caring for amputees are doing laboratory work, each specializing on a particular limb. Walter Bura, head of the division of prosthetic services of the Veterans Administration, states that the program will be permanent.

Antivivisection Bill to Get Hearing Next Month

A public hearing, possibly in February, has been promised on the Lemke antivivisection bill by the House District committee. Spokesmen have assured Representative Lemke, Republican of North Dakota, that his bill will have an early hearing.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Scientific Research

Senator Willis, Indiana, for himself and Senator Hart, Connecticut, Senator Hawkes, New Jersey, Senator Hickenlooper, Iowa, Senator Smith, New Jersey, Senator Stanfill, Kentucky, Senator Wiley, Wisconsin, and Senator Young, North Dakota, has introduced S. 1777 to establish a National Science Foundation as a corporation, the initial members of which will be fifty recognized leaders in the fields of fundamental science, social sciences, medicine, engineering and education, and lay persons of recognized standing in public affairs. The initial members will be appointed by the President from nominations requested by him from the National Academy of Sciences for those fields within the province of the academy and from recognized national organizations in those fields outside that province. The foundation will be authorized to fill vacancies in its membership and to appoint a chief executive officer. It will be authorized to report annually to Congress on the monetary needs of American institutions with regard to research and training in all departments of science. It will aid by means of scholarships and fellowships in these departments. It will be required to request advice from the National Academy of Sciences in matters relating to the physical and biologic sciences and mathematics, including basic medicine and engineering.

Congressman Luce, Connecticut, has introduced H. R. 5332 to establish an executive department in the government to be known as the Department of Science and Research, to foster, promote and develop the study and spread of scientific knowledge and its practical application. There will be five bureaus in this department: (1) a bureau of Physics and Mathematical Science, (2) a Bureau of Public Health and Social Science, (3) a Bureau of Scientific Education and Information, (4) a Bureau of the Biological Sciences and (5) a Bureau of Engineering and Technological Sciences.

Charitable Deduction from Income Taxes

Representative Luce, Connecticut, has introduced H. R. 5296, providing that, beginning with the taxable year 1946, physicians, surgeons and dentists shall be permitted an additional credit as a deduction on their income tax equal in terms of percentages to that portion of their time each year which is devoted to charity, free clinic work and public research work.

Health of School Children

A joint resolution, S. J. Res. 137, has been introduced by Senator Morse, Oregon, proposing that the Secretary of Labor, acting through the Children's Bureau and in cooperation with federal, state and local agencies and qualified institutions of higher education, shall (1) make studies of the health and physical status of children of school ages, (2) make studies of the facilities and services offered by schools for the correction of physical defects of children of school ages and (3) recommend the use of and demonstrate in representative urban and rural areas methods of conducting school health examinations and providing school health services. For the fiscal year ending June 30, 1946 an appropriation of $100,000 will be authorized and for each of the next two fiscal years $450,000.

Miscellaneous

Senator Pepper, Florida, for himself and Senator George, Georgia, Senator La Follette, Wisconsin, and Senator Taft, Ohio, has introduced S. 1779 proposing to authorize the Federal Security Administrator, through such officers or employees or units of the Federal Security Agency as he may designate, to assist the several states, their political subdivisions and nongovernmental organizations (1) to develop and carry out, particularly in areas where such measures are of importance to military or naval personnel, measures designed to prevent prostitution, eliminate conditions contributing to sex delinquency and provide services for the rehabilitation of sex delinquents and (2) to foster cooperation in communities among law enforcement, welfare and other public and private activities for the purpose of preventing prostitution, eliminating conditions contributing to sex delinquency and providing services for the rehabilitation of sex delinquents. For the fiscal year ending June 30, 1947 an appropriation of $700,000 is to be authorized and so much as may be necessary for each fiscal year thereafter.

S. 1769, introduced by Senator McFarland, Arizona, proposes to amend the Social Security Act to provide for an increase of 35 per cent in the federal share of old age assistance, aid to dependent children and aid to the blind.

STATE LEGISLATION

Georgia

Bills Introduced.—H. R. 170 proposes a resolution to amend the state constitution to create a State Board of Health with authority over all matters relating to the health and life of the people of the state. H. 695 proposes to require both parties to a marriage to present a certificate signed by a qualified physician, licensed to practice medicine and surgery in any state or United States territory, stating that the applicant has been given an examination and is not infected with syphilis. H. 712, to amend the act relating to the licensing of pharmacists, proposes that applicants for registration shall be graduates of a high school and shall have attended a generally recognized college of pharmacy for a period of two years. H. 734 proposes that all persons between the ages of 14 and 50 should have their blood examined for syphilis by an approved laboratory test. H. 771, to amend the workmen's compensation law, proposes that verified copies of all medical reports of claimants be sent immediately to the claimant or his attorney and to the State Board of Workmen's Compensation.

Bills Passed.—H. 655, to amend the law relating to the qualifications of applicants for a license to practice nursing, passed the house January 21. It proposes to reduce from 21 to 20 the required age of the applicant. H. 732 passed the house January 21 and the senate January 26. It proposes to authorize the Board of Health to make and promulgate reasonable rules and regulations for the protection of the health and lives of inmates and patients of hospitals, sanatoriums, infirmaries, maternity homes, nursing homes and other institutions where persons are received for treatment, examination, maternity care or nursing care in the state. In connection therewith a hospital advisory committee would be established, to consist of three members appointed by the Medical Association of Georgia or its board of councilors; the total membership of the advisory committee would number fourteen.

Kentucky

Bills Introduced.—S. 56, to amend the law relating to the practice of pharmacy, proposes that applicants for a license to practice pharmacy must be citizens of the United States, must have graduated from a school or college of pharmacy recognized and approved by the Kentucky Board of Pharmacy and must submit proper affidavits showing a minimum of one year of experience in a retail pharmacy under the supervision of a registered pharmacist. H. 87 and S. 30, to amend the workmen's compensation act, propose to increase the number of persons on the medical committee of the workmen's compensation board from three to five and further propose that such committee shall include at least one surgeon and one neurologist. H. 96 proposes the creation of a Kentucky State Board of Naturopathic Examiners to examine, license and regulate persons desiring to practice naturopathy, which is defined by the bill as being "a distinct system of healing based upon its own philosophy and teachings as to the causes of disease, the prevention and cure of human illness, and the maintenance of health. It means 'Nature-Cure, or Health by Natural Methods'; it embraces the prevention, diagnosing and treating human beings with their injuries, ailments or diseases, by the use of one or more of the physiological, physical or mechanical, chemical or material, forces or agencies of nature. It is a science and art of assisting nature in elimination, maintenance, and revitalization, using all methods and modalities that will assist in removing toxins and pathologies, restoring cell vitalization and remineralization without destruction of vital force, as taught in naturopathic schools, colleges, or universities teaching courses of not less than four years of nine months each, covering not less than forty-four hundred class hours of fifty minutes each, covering a curriculum peculiar to the art and science and practice of naturopathy." The proposal would further authorize licensees thereunder to practice naturopathy in accordance with the state health laws and in conformity with the teaching of class A naturopathic schools, "embracing the use of phytotherapy (the use of herbs and the facts thereof, provided the same is not under the narcotic law), minor surgery, meaning the breaking or severing the skin or membrane, or and orificial work, obstetrics and gynecology, autotherapy and biologicals, and shall enjoy right and privileges equal to those enjoyed by other physicians practicing in this commonwealth." Licensees hereunder would be authorized to sign death certificates and execute all legal documents and certificates with the same authority as under the law members of other schools or systems of treatment may do.

Massachusetts

Bills Introduced.—H. 771 proposes that any person entitled to soldier's relief under the general laws shall have the right to procure necessary treatment by a doctor, dentist, nurse or hospital of his own choosing, and the reasonable charges made by such doctor, dentist, nurse or hospital for services rendered shall be paid by the appropriate municipal authorities. H. 782 and H. 794, to amend the law relating to recipients of old age assistance, propose that aid given shall include the reasonable amount of necessary and proper expenses for medical, hospital and other services rendered to such person. H. 844, to amend the law relating to nonprofit hospital service corporations, proposes that every corporation subject to this chapter be declared to be a charitable corporation. The existing law exempting the property of such corporation from state, county, district and municipal taxes is repealed. H. 1132, to amend the law relating to actions for personal injuries, proposes that a physician or surgeon who makes a physical or mental examination of an injured person in connection with any claim for damages for personal injuries shall be deemed to be the agent of the party for whose information the examination was made for the purpose of answering interrogatories. H. 1180, to amend the law relating to recipients of old age assistance, proposes that such assistance shall include the services of a physician of such recipient's choice if said physician meets the requirements of the Massachusetts Medical Society. H. 1339 proposes a comprehensive act relating to the regulation of animal experimentation. H. 1340, to amend the law relating to animal experimentation, proposes that whoever purchases or acquires a dog, cat or bird to be used for experimentation or multilation while alive shall keep a record and submit a report to the commissioner of public safety of each such transaction showing the source from which such animal or bird was obtained. H. 1380 proposes the establishment of a hospital clinic in downtown Boston to receive and care for veterans who require medical aid or treatment at any hour of the day or night. H. 1401 proposes that every physician, surgeon or dentist who has served for any period of time in the armed forces shall be exempt from the payment of any fee or charge otherwise payable by him under the laws of the state.

Mississippi

Bills Introduced.—H. R. 10 proposes a resolution memorializing the Congress of the United States to enact suitable and adequate legislation for the training of doctors at government expense to take care of personnel of the United States armed forces wounded in the service of the country. H. 72 proposes the creation of a four year medical school as a department of the University of Mississippi which shall be operated as a class A medical school in accordance with the "Council of Medical Education" of the American Medical Association. H. 73 proposes the creation of a Memorial Hospital Commission to establish a War Memorial Hospital which shall maintain and operate a cancer clinic and perform research work in cancer and other diseases. H. 106, to amend the law relating to the operation of a Mississippi State Insane Hospital, proposes that neither the superintendent nor any other person legally participating in the execution of the treatment and regimen prescribed for a patient therein shall be liable either civilly or criminally on account of said participation. H. 276 proposes that all residents of the state on reaching his or her sixteenth birthday shall submit to a medical examination as to the absence or presence of venereal disease. The medical examination shall be made by any licensed physician selected by the person to be examined. S. 45 proposes the creation of a four year medical school and a university hospital to be built, established, maintained and operated in the state of Mississippi, the school to maintain standards of schooling and teaching which shall be in accordance with the standards approved by the Council on Medical Education and Hospitals of the American Medical Association and of the Association of American Medical Colleges. The proposal would also create a "Physicians Advisory Board" consisting of five physicians, who shall be members in good standing of the Mississippi State Medical Association. S. 90 proposes to authorize the State Board of Health to maintain injunctive procedures to enjoin and profit any person from the practice of any profession required to be licensed by said board when such person is practicing said profession without having first obtained such license.

Bills Passed.—S. 80 passed the Senate January 29. It proposes to require applicants for a marriage license to present a certificate showing freedom from venereal disease. The certificate may be executed by an active licensed physician in Mississippi, or a physician licensed to practice in any or all of the other states of the United States, or the District of Columbia, or by a commissioned medical officer on active duty in the armed forces of the United States, or by a medical officer of the United States Public Health Service. When the applicant is unable to pay for such certificate, the certificate may also be executed by any full time county health officer in the state who is a regular graduate of medicine and is licensed to practice medicine in Mississippi.

Missouri

Bills Introduced.—H. 831, to amend the law relating to the appointment of deputy state commissioners of health, proposes that the county courts of any county be authorized to appoint as a deputy state commissioner of health a duly licenced qualified physician. The existing law requires only the appointment of a reputable physician. S. 359 proposes the establishment within the department of education of a division of registration and examination to coordinate the work of existing boards of registration and examination, including the state board of medical examiners, the state board of chiropractic examiners and the state board of osteopathic registration and examination.

New York

Bills Introduced.—A. 326, to amend the hospital lien law, proposes that, where an injured person receives treatment, care and maintenance in a hospital ward, cost rates shall for the purposes of this section be deemed equivalent to the scheduled rates currently approved by the industrial commissioner and the superintendent of insurance for cases under the workmen's compensation law. The lien of the hospital shall not extend to personal services rendered by a physician or surgeon, however. A. 470 and S. 470, to amend the labor law, propose that the illness or disability of a claimant causing his unemployment must be certified by a physician or surgeon duly licensed to practice in the state of New York. S. 434, to amend the law in relation to maternal and child health, proposes that the commissioner of health be required to act in an advisory and supervisory capacity in matters pertaining to the safeguarding of motherhood, the saving of infant life and the prevention of the diseases and defects of childhood. S. 469, to amend the unemployment insurance law, proposes that the sickness or accident disability causing the claimant to be unemployed shall be certified under oath by a physician or surgeon duly licensed to practice in the state of New York. S. 709, to amend the insurance law, proposes that the superintendent of insurance be authorized to withhold his approval of an accident insurance or health insurance form if any such form or any application, rider or endorsement to be used in connection therewith contains provisions which are unjust, unfair, inequitable, misleading or contrary to law or the public policy of the state.

Virginia

Bills Introduced.—H. 39 and S. 45 propose that the governor be authorized to execute insurance contracts for group hospitalization and surgical benefits for state employees who become participating members of the plan. H. 58 and S. 52 propose that the state department of health be authorized to establish a program for the medical examination of all children in the public free schools, such examination to be sufficient to disclose the health, physical condition and defects of such public school children. H. 66 proposes that the state department of health be directed to establish a program for the education of the citizens of the state engaged in agriculture and industry of the value and benefits of prepaid hospital and medical care and to appropriate the sum of ten thousand dollars for such program. S. 51, to amend the law relating to marriage and divorce, proposes that it shall be sufficient grounds for divorce when either spouse has been adjudicated insane, committed to and continuously confined for five or more years in one or more institutions for the confinement and treatment of insane persons and is shown to be incurable. The divorce would not be granted until after a thorough examination of the insane defendant by three physicians of recognized ability in mental diseases has been made. S. 64 proposes the creation of a Commission on Post-Mortem Examinations and the appointment of a Chief Medical Examiner who shall be a skilled pathologist and eligible to be licensed as a Doctor of Medicine. The Chief Medical Examiner would be provided with an office and laboratory having adequate professional and technical personnel and physical facilities for the conduct of postmortem examinations and of such pathologic, bacteriologic and toxicologic investigations as may be necessary or proper. The section dealing with the appointment of coroners would provide that each coroner shall be appointed from a list of two or more licensed doctors of medicine submitted by the component medical society of the county or city in which the appointment is to be made. S. 72 proposes to authorize the state board of public welfare to provide reasonable rules and regulations for the construction, maintenance and operation of boarding homes, homes for the aged and other similar homes, the word "home" meaning "any place, establishment or institution operated or maintained for the maintenance or care of two or more aged, infirm, chronically ill or incapacitated persons." The proposal would exempt from its provisions any hospital, nursing home, maternity home, children's home or other home or institution which is already or may hereafter be subject to regulation by the board. S. 73 proposes the creation of a sanatorium for white residents affected with nervous diseases, mental diseases, alcoholism or drug addiction, to receive modern sanatorium care and treatment.

Coming Medical Meetings

Annual Congress on Medical Education and Licensure, *Chicago, Feb. 11-12.* Dr. Victor Johnson, 535 North Dearborn St., Chicago, Secretary.

American Association of Anatomists, Cleveland, April 4-6. Dr. Eliot R. Clark, University of Pennsylvania School of Medicine, Philadelphia 4, Secretary.

American Association of Pathologists and Bacteriologists, Chicago, March 8-9. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland, Secretary

American Orthopsychiatric Association, New York, Feb. 14-16. Dr. Nina Ridenour, 1790 Broadway, Room 916, New York 19, Secretary.

American Physiological Society, Atlantic City, March 11-15. Dr. Wallace O. Fenn, 260 Crittenden Blvd., Rochester 7, New York, Secretary.

American Society for Experimental Pathology, Atlantic City, March 11-15. Dr. Harry P. Smith, 630 W. 168th St., New York 32, Secretary.

American Society for Pharmacology and Experimental Therapeutics, Atlantic City, March 11-15. Dr. Raymond N. Bieter, University of Minnesota Medical School, Minneapolis, Secretary.

American Surgical Association, Hot Springs, Va., April 2-4. Dr. Warfield M. Firor, Johns [illegible] more 5, Secretary.

Chicago Medical Sc [illegible] ference, *Chicago,* March 5-8. Dr. Warren W. [illegible] Ave., Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, March 18-21. Dr. John G. Young, 1719 Pacific Avenue, Dallas 1, Director of Clinics.

Federation of American Societies for Experimental Biology, Atlantic City, March 11-15. Dr. D. R. Hooker, 19 West Chase Street, Baltimore 1, Secretary.

Medical Library Association, New Haven, Conn., March 25-27. Miss Frida Pliefke, 2000 Medical Arts Bldg., Minneapolis 2, Secretary.

Missouri State Medical Association, St. Louis, March 24-26. Dr. Ralph L Thompson, 634 N. Grand Blvd., St. Louis 3, Secretary.

National Conference on Medical Service, Chicago, February 10. Dr. Cleon A. Nafe, 822 Hume-Mansur Bldg., Indianapolis 4, Secretary.

Southeastern Surgical Congress, Memphis, Tenn., March 11-13. Dr. Benjamin T. Beasley, 45 Edgewood Ave. S.E., Atlanta 3, Georgia, Secretary.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Los Angeles Association Plans Addition to Building.—The Los Angeles County Medical Association plans to build an addition to provide much needed stack room facilities for the library and office and community rooms for the association itself.

New Section on General Practice.—On January 24 the organization meeting of the section on general practice of the Los Angeles County Medical Association was held under the chairmanship pro tem of Dr. Eric A. Royston and secretaryship pro tem of Dr. H. Vern Soper, both of Los Angeles.

Hospital Staff Cooperates to Reduce Accidents.—On January 15 the medical staff of the San Antonio Community Hospital, Upland, met in conference with law enforcement officials of the West End of San Bernardino County, the morticians and ambulance owners and judges of the various courts and representatives of the press to discuss and make recommendations of ways and means to reduce materially the heavy unnecessary traffic fatalities. The conference was the result of the recognition that traffic deaths and personal injuries had increased since V-J day, Aug. 14, 1945. A committee of three was named to draw up a resolution carrying recommendations to reduce these accidents, and copies were sent to local and national authorities as well as to the members. The resolution urges the following:

More traffic officers and greater frequency of patrol.

Driver educational program and (*a*) educational program in junior and senior high schools, with "behind the wheel" actual instruction; (*b*) prerequisite training and certification before issuance of driver's license; (*c*) physician's approval of ability of driver with physical disability.

All drivers involved in accidents to be reexamined within thirty days or driver's license revoked:

(*a*) Immediate revocation of licenses of all drivers involved in accidents resulting in personal injury or death, pending reexamination.

(*b*) Drivers apprehended operating a motor vehicle without a license to be incarcerated in county jail for a term of not less than ninety days and during such incarceration, at the discretion of the department of motor vehicles, perform such duties in the general program to enhance the safety of our highways.

Heavier and uniform fines and sentences along with impounding of cars on all violations of drunken driving and/or reckless driving and/or driving without due caution or any wanton disregard of safety on the highway.

Improved engineering on all main highways; to be at least four lane divided highways:

(*a*) Immediate survey of dangerous intersections and removal of all obstructions impairing visibility.

(*b*) More frequent location checks on mechanical equipment and driving ability by all traffic officers.

(*c*) Adequate flood lighting of intersections, particularly those used by pedestrians, and all main intersections.

COLORADO

Midwinter Postgraduate Clinics.—The eleventh annual midwinter postgraduate clinics conducted by the Colorado State Medical Society will be held at Denver hospitals and the Shirley Savoy Hotel, February 27-March 1. This will be the first revival of the Denver midwinter clinical session since 1942, when war conditions forced its indefinite postponement. Among the speakers will be:

Dr. Edward L. Compere, Chicago, The Treatment of Compound Fractures.
Dr. Bruce K. Wiseman, Columbus, Ohio, Hypersplenism and the Blood Dyscrasias.
Dr. Henry G. Poncher, Chicago, Fever as a Diagnostic Problem in Infants and Children.
Dr. Frederic E. B. Foley, St. Paul, The Part of the General Practitioner in the Management of Vesical Neck Obstruction.
Dr. M. Edward Davis, Chicago, The Modern Management of Placenta Previa.
Dr. J. Dewey Bisgard, Omaha, The Cancer-Ulcer Problem of the Stomach.
Col. John B. Grow, M. C., Denver, The Modern Approach to Neoplasms of the Chest.

DELAWARE

Thirty Years as Editor.—Dr. W. Edwin Bird, Wilmington, observed his thirtieth anniversary as editor of the *Delaware State Medical Journal* with the December issue. In editorial comment the journal states that Dr. Clarence A. Smith, Seattle, of *Northwest Medicine* has served for forty-two years and Dr. Holman Taylor, Fort Worth, Texas, of the *Texas State Journal of Medicine* for thirty-six years.

ILLINOIS

Personal.—Dr. Ruth E. Church, who has been medical director of the District Health Unit Number 7 at Washington, Iowa, for several years, has resigned to become director of the McDonough-Fulton Bi-County Health Department, with headquarters in Macon and Canton, effective December 1.

Chicago

Personal.—Dr. Robert Neubaur, head of the medical division of the Yugoslav Red Cross, was guest at a dinner on January 25 given by the Chicago chapter of the American Committee for Yugoslav Relief.——Albert L. Raymond, Ph.D., formerly a member of the staff of the Rockefeller Institute for Medical Research and recently director of research of G. D. Searle and Company, has been appointed vice president in charge of research of the company.

Society News.—Dr. Herbert S. Ratner, Hinsdale, Ill., director of the student health service, Loyola University School of Medicine, lectured at the Marquette University School of Medicine, Milwaukee, on the "Extramedical Element in the Therapeutic Decision."——John L. Bach, associate director of public relations, American Medical Association, addressed the Lions Club, Michigan City, Ind., January 23 on "Fifty Years of Medical Progress."——At the recent meeting of the Chicago Tuberculosis Society Drs. Jacob J. Mendelsohn was elected president, Arthur S. Webb, Wheaton, vice president and Hugo T. Cutrera secretary-treasurer.

New Appointments at Illinois.—Dr. Douglas A. MacFadyen and Dr. George M. Hass have been appointed Rush professor of biochemistry and Rush professor of pathology, respectively, in the Rush-Presbyterian Hospital division of the University of Illinois College of Medicine. Dr. MacFadyen previously was chief of the division of chemistry and physics of the Army Medical Center in Washington and Dr. Hass was chief of the department of pathology of the School of Aviation Medicine, Randolph Field, Texas, both with the rank of major. The appointments constitute an important step in the achievement of an expanded research and teaching program involving the basic medical departments of the Rush-Presbyterian Hospital division.

INDIANA

Health Center Named for Dr. Morgan.—The new health center at Flanner House has been named in honor of the late Dr. Herman G. Morgan, in recognition of his thirty-five years' service as secretary of the Indianapolis Board of Health (THE JOURNAL, Sept. 8, 1945, p. 140).

Personal.—Dr. Miles F. Daubenheyer, Holton, has been named superintendent of the Muscatatuck State School, Butlerville, succeeding Dr. Otis R. Lynch, who resigned to become superintendent of the Richmond State Hospital.——Dr. James M. Burk has resigned as secretary of the Decatur Board of Health, effective January 1.——Dr. Richard N. Washburn, Rensselaer, has been appointed coroner of Jasper County to fill the unexpired term Dr. Merle D. Gwin, who has moved to Florida.

School of Health and Physical Education.—Indiana University, Bloomington, has announced the establishment of a school of health, recreation and physical education as the first step in the university's postwar development program. The school will have four departments: physical education offering service courses in all schools of the university; health and safety, giving courses in these subjects together with a program of research and graduate study; recreation, coordinating all campus activities and student intramural sports, with courses designed to train directors of community and school recreation programs, and professional physical education, offering technic courses for teachers, also with research and graduate study programs.

Division of Adult Hygiene and Geriatrics.—Dr. William F. King, Indianapolis, formerly health commissioner of Indiana, is director of the recently created division of adult hygiene and geriatrics of the state department of health. The new division was authorized at the last session of the Indiana general assembly (THE JOURNAL, March 17, 1945, p. 663). The *Journal of the Indiana State Medical Association* points out that to be concerned with factors of aging and problems of the aged is a relatively new and untried activity of the public health administration. It stated that the number of men and women in Indiana who have attained the age of 60 and over is in excess of three hundred and fifty thousand. The number in this age group in the continental United States is estimated at above thirteen million. Within the last census decade 1930 to 1940 there was an increase in the number of persons 65 years of age and over of 35 per cent, while in contrast the total population increase was but 7.2 per cent in the same period.

IOWA

Personal.—Effective January 1, Dr. Everett M. George, Des Moines, who recently returned from service with the U. S. Navy, assumed the position of editor of the *Journal of the Iowa State Medical Society.* He succeeded Dr. Lee F. Hill, Des Moines, who had held the position for the past nine years.

Course on Tropical Diseases.—A second laboratory training course on parasites of malaria, amebiasis and tropical diseases was recently held at the State Hygienic Laboratory, Iowa City. The course was sponsored by the State University of Iowa College of Medicine, Iowa City, and the Iowa State Department of Health in cooperation with the U. S. Public Health Service. The first course of this kind took place July 23-28, 1945. Those in attendance at the two courses totaled fifty-eight, including fifty-four laboratory workers and four physicians representing thirty-one counties and thirty-five hospitals in all parts of the state.

MASSACHUSETTS

The Cutter Lecture.—Dr. Donald Hunter, physician to the London Hospital, London, recently gave the Cutter Lecture on Preventive Medicine at the Harvard Medical School, Boston, on "Research in Industrial Medicine in Great Britain at War."

Study of Dental Caries.—The Dental Bureau of the Massachusetts Department of Public Health, Boston, in preparation for conducting a research program in the control of dental caries, is making a survey to determine the incidence of caries among children by age groups and to determine the availability of sufficient dentists to cope with the existing problem. The fluoride control of all public water supplies in the state has already been determined and in only one town, Farumsville, was as much as 1 part per million of sodium fluoride (1.3 parts per million) found. In all other public water supplies the amount of sodium fluoride was near 0.2 part per million. These data will be used as the basis for the proposed study, which will investigate the control of dental caries by utilizing fluorides in public water supplies, in prophylactic pastes and mouth washes, in pastilles and lozenges, in pills and in topical applications. In each community where the study is being conducted 250 children are participating, and a like number are serving as the control.

MICHIGAN

Personal.—Dr. Louis P. Munger, Hart, recently completed fifty years in the practice of medicine.——Dr. Sylvester E. Gould, Eloise Hospital, Eloise, has been appointed editor in chief of the *American Journal of Clinical Pathology* to succeed Dr. Israel Davidsohn, Chicago.

Society Honors Members Who Served in War.—The Saginaw County Medical Society gave a dinner recently to welcome home its members who have been in military service. Dr. Alexander R. McKinney, Saginaw, was toastmaster at the banquet, at which wives of members and widows of former members were guests.

Meeting on Cancer.—The Genesee County Medical Society will devote its meeting March 20 to a symposium on cancer, to be presented by:

Dr. Louis E. Phaneuf, Boston, Cancer of the Uterus.
Dr. Paul A. O'Leary, Rochester, Minn., Cutaneous Malignancy.
Dr. Charles B. Huggins, Chicago, Cancer of the Genitourinary System.
Dr. Frederick A. Coller, Ann Arbor, Cancer of the Stomach.
Dr. Frank E. Adair, New York, Cancer of the Breast.

NEW JERSEY

New Director of Preventable Disease.—Dr. Leonid S. Snegireff, Trenton, has been appointed director of the bureau of preventable diseases of the New Jersey State Department of Health, according to the *Bulletin* of the National Tuberculosis Association. The new bureau includes divisions covering tuberculosis and venereal disease control, maternal and child health, preventive medicine, industrial and dental health and health education. Dr. Snegireff was formerly medical assistant in the department of health.

Brandenburg Arrested on Abortion Charge.—A ring charged with performing illegal operations was broken up January 18 when Bergen county and state police raided a farm house on a 25 acre estate in Park Ridge and arrested six persons. The New York *Times* reported that, according to Michael Orrechio, detective chief of Bergen County, the ring was headed by Dr. Leopold W. A. Brandenburg, Union City, who has a long record of arrests (THE JOURNAL, Sept. 30, 1944, p. 310). Among those arrested with Dr. Brandenburg were Mrs. Sadie Strohmeyer, North Plainfield, who was convicted on abortion charges in 1939 and who was on a five year probation. The bail for Brandenburg was set at $25,000 and for Mrs. Strohmeyer at $10,000. The other persons' bail was set at $5,000 each. Dr. Brandenburg has been mixed up in a number of irregularities, such as violation of narcotic laws, possession of stolen goods and harboring a fugitive by removing finger prints.

NEW YORK

Dr. Conway Ends Thirty-One Years' Service.—Dr. John A. Conway, district health officer with headquarters in Hornell, resigned January 1, concluding thirty-one years' service in the state department of health. Dr. Conway was one of the first six physicians appointed on the department staff in 1914 under the title of "district sanitary supervisor," a position corresponding to the present "district state health officer." He is the only one of the original appointees who has served continuously in the same position to the present time. For many years he has served the counties of Allegany, Chemung and Steuben from headquarters in Hornell. At one time he was president of the Steuben County Medical Society.

Rabies Consultant Appointed.—Alexander Zeissig, D.V.M., has been appointed veterinary consultant on rabies on the staff of the division of communicable diseases of the state department of health. In this capacity he will organize a statewide program for the control of rabies, including preventive measures for application in advance of the appearance of the disease. Dr. Zeissig in 1930 was awarded a fellowship in medicine by the National Research Council and studied for one year at the medical school at Heidelberg, Germany. Since his return to this country in 1931 he has been associated continuously with the New York State Veterinary College, first as assistant professor and later as associate professor of bacteriology.

New York City

The Biggs Memorial Lecture.—Laurence H. Snyder, Sc.D., professor of medical genetics, Ohio State University College of Medicine, Columbus, will give the annual Hermann M. Biggs Memorial Lecture at the New York Academy of Medicine, April 4. His subject will be "Medical Genetics and Public Health."

Society Honors Past Presidents.—The Medical Society of the County of Kings will hold a dinner February 20 in the Hotel St. George, Brooklyn, to honor its immediate past presidents. The society voted the annual dinner honoring the retiring presidents in 1941 but discontinued the practice during the war. The physicians to be honored are Drs. William C. Meagher, John J. A. Gainey, Leo S. Schwartz and Joseph Tenopyr, all of Brooklyn. They will be given medals and scrolls. Dr. Morris Fishbein, Editor of THE JOURNAL, will discuss "Medicine and the Postwar World."

Student Society.—At a recent meeting of the Contin Society, honorary scholastic society of the New York Medical College, Flower and Fifth Avenue Hospitals, Dr. Thomas H. Evans, research professor of anatomy, was elected to honorary faculty membership. Senior students chosen for membership include Lesley M. Warshaw, Julius Stein, Sidney J. Peck, Robert Maxfield and Ednita P. Bernabeu. Undergraduates chosen from the junior class were Peter Laderman, Burton L. Wise, Herbert M. Eskwitt, Morton P. Lazar, Max Cohen and Norman Ackerman. Mr. Ackerman is secretary of the Contin Society.

Friends of Medical Research.—A group known as the Friends of Medical Research has been organized to inform the public about animal experimentation and its contribution to public health. The organization was launched under the auspices of the New York Academy of Medicine, and Dr. Simon Flexner has been named honorary president. The first efforts of the new organization are to be directed toward the defeat of the DiCostanzo-Davidson bill in the state legislature to make research work with dogs unlawful. It is intended that the statewide organization shall be coordinated with similar ones in every county of the state, one of which has already been organized in Rochester and Monroe County.

Robert Potter Teaches First College Course in Science Reporting.—Robert D. Potter, science editor of the *American Weekly* and former president of the National Association of Science Writers, will teach the first college course in science reporting and editing at New York University, it was announced January 24. The course has been organized to meet a demand for trained science writers brought on by the interest in scientific subjects which has grown out of the war. It is the culmination of several months' planning by the National Association of Science Writers and will be offered on Wednesday evenings from 8 to 10 during the spring term beginning in February. The needs of different mediums, an examination of sources and tools needed by the science writer, and a discussion of science terminology will feature the course. Each student will be given regular science writing assignments from learned journals and will have his articles discussed and edited by the instructor. A critical discussion of science stories which reach an editor's desk will be held at each class session. Mr. Potter was formerly with the New York *Herald Tribune* and Science Service and was acting chairman of the department of general science at the New York University School of Commerce during the war.

Internal and Psychosomatic Medicine.—Cornell University announces a project in internal medicine at the New York Hospital designed to deal clinically and experimentally with psychosomatics. The principal objects are to develop a practical method of dealing with ambulatory clinic patients who suffer from symptoms related to their emotional states and life situations, to engage in experimental study of the mechanisms involved in illness of this nature and to train especially able young physicians in experimental methods and a critical psychosomatic approach to the care of the sick. About half time will be spent in the diagnosis and management of patients and half time in research dealing mainly with mechanisms underlying symptoms. The project will be under the direction of Dr. Harold G. Wolff, assisted by Dr. Stewart Wolf, internist, Dr. Herbert S. Ripley Jr., a psychiatrist, and six fellows. Fellows will be appointed for a period of one year with the expectation of serving for two or more. Candidates for fellowship, who will receive a salary of $2,500 a year for the first year, should have had at least two years in internal medicine and have given evidence of a psychiatric orientation. They need not necessarily have had experience in research but must have a serious interest in investigation, energy and curiosity. Prospective candidates should arrange for a personal interview through Dr. David P. Barr, New York Hospital, 525 East Sixty-Eighth Street, New York.

NORTH CAROLINA

Portraits of Physicians.—Portraits of Drs. Richard H. Whitehead and Charles S. Mangum were presented to the University of North Carolina School of Medicine December 2. Dr. Whitehead was dean of the medical school from 1891 to 1905, when he went to the University of Virginia; he died in 1916. Dr. Mangum was on the medical school faculty from 1896 until his death in 1939, serving as dean from 1933 to 1937. Dr. George L. Carrington, Burlington, president of the University Medical Alumni Association, presided at the ceremony, which took place in the library of the medical school.

OHIO

Changes in Health Personnel.—Dr. Arthur B. Ream, Batavia, has resigned as health commissioner of Clermont County to engage in private practice in Mechanicsburg.——Dr. George A. Poe, Port Clinton, is the new health commissioner of Ottawa County.

Isaac Harris Named Professor Emeritus.—Dr. Isaac B. Harris, professor of clinical surgery, Ohio State University College of Medicine, Columbus, has retired with the title of emeritus professor. Dr. Harris graduated at Starling Medical College in 1900, joining the faculty in 1904 after finishing advance study at the Harvard Medical School and the New York Postgraduate Medical School. He has continued on the staff steadily since then. The present name of the Starling College is the Ohio State University College of Medicine.

Cleveland Clinic Observes Twenty-Fifth Anniversary.—The Cleveland Clinic will celebrate its twenty-fifth anniversary, February 24-27. The opening will be held in the auditorium of the Cleveland Medical Library. A "Refresher Course in Treatment," consisting of a series of lectures and demonstrations, will be given at the clinic. In connection with this course Edmund N. Cowdry, Ph.D., St. Louis, will address a dinner meeting on "Precancerous Lesions." Dr. Bertrand E. Lowenstein, instructor in the department of physiology of Yale University School of Medicine, has joined the division of research at the Cleveland Clinic and will carry on genitourinary investigations under the terms of the Packard Endowment gift, it is reported.

OKLAHOMA

New Executive Secretary.—E. G. Green, educational director of the Oklahoma County Health Association, Oklahoma City, has been appointed acting executive secretary of the association for a minimum of one year. Arthur H. German, who was executive secretary for seven years, resigned to become consultant to the fund raising department of the Midwest division of the American Red Cross with offices in St. Louis. Mr. Green was a member of the original board of the old Tuberculosis Society of Oklahoma City, which was a forerunner of the Oklahoma County Health Association, chartered with its services expanded April 22, 1943.

OREGON

Course in Ophthalmology.—The sixth annual spring postgraduate course in ophthalmology and otolaryngology will be held in Portland, April 15-20, under the auspices of the Oregon Academy of Ophthalmology and Otolaryngology and the University of Oregon Medical School, Portland. Guest speakers will include Drs. Algernon B. Reese, professor of ophthalmology at Columbia University College of Physicians and Surgeons, New York, and Gabriel Tucker, professor of bronchoscopy and esophagology at the University of Pennsylvania School of Medicine, Philadelphia.

PENNSYLVANIA

Change in Health Board Secretary.—Dr. Charles V. Hogan, for fifteen years a member of the Pottsville Board of Health, has been named secretary to succeed H. J. Herbein, D.D.S., who resigned December 1 after holding the position about thirty-three years. Dr. Hogan has served as member and president of the board for fifteen years.

Philadelphia

The Ulrich Memorial Lecture.—Dr. Thaddeus L. Montgomery, professor of obstetrics and gynecology, Temple University School of Medicine, gave the second annual George A. Ulrich Memorial Lecture February 6 at Jefferson Medical College. The lecture, which was entitled "The Placenta," is sponsored by the Alpha Kappa Kappa medical fraternity, of which John D. Bealer is corresponding secretary. The lecture is named for Dr. George A. Ulrich, who died in 1944. He had been clinical professor of obstetrics at Jefferson and had graduated there in 1901.

Mental Hygiene Lectures—Cancer Seminars.—On January 28 the Philadelphia County Medical Society launched a series of public lectures on various phases of mental hygiene. The initial speakers were Drs. James J. Waygood on "The Emotional Needs of the Infant and Young Child," and Ralph M. Tyson on "The Emotional Factors During Illness in Children." The society gave the first in a series of four cancer seminars January 24 on Cancer of the Breast; others in the series are Pelvic Cancer, February 21, Cancer of the Esophagus and Stomach, March 21, and Cancer of the Colon, April 18.

Fifty Years of Practice.—At a luncheon meeting of the first councilor district of the Medical Society of the State of Pennsylvania, January 8, at the Philadelphia County Medical Society, the following members of the county medical society received framed certificates from the state society in recognition of having been in the practice of medicine for a period of fifty years: Drs. W. Wayne Babcock, Richard D. Burke, Cunningham P. Clark, Clarence H. Fritz, Alfred Gordon, Edwin A. Heller, Daniel J. McCarthy, Louis H. Mutschler, Herbert Old, Charles S. Raue, George N. Richmond, Thomas T. Thomas, Joseph P. Walsh, Rachel R. Williams, and Christian G. Yaeger, Elizabeth L. Pickett, Aldan, Pa., and Henry Archer Cleaver, Wilmington, Del.

TEXAS

Gynecologic Survey of Women in State Institutions.—A comprehensive gynecologic survey of women in Texas state institutions is being organized under the direction of Dr. Willard R. Cooke, professor of obstetrics and gynecology at the University of Texas Medical Branch, Galveston, and his associate, Dr. John D. Weaver. This survey is being made in cooperation with the state board of control with Judge Weaver Baker as chairman. It is supported by a three year grant of $20,000 from the Lilly Research Laboratories of Indianapolis.

Grants for Research.—The Lilly Research Laboratories, Indianapolis, have made a grant of $2,500 to the University of Texas Medical Branch, Galveston, to establish a training fellowship in tissue culture, with special reference to the reticuloendothelial system. The work will be under the direction of Charles M. Pomerat, Ph.D., professor of anatomy and director of the tissue culture laboratory. The National Foundation for Infantile Paralysis has made a grant of $3,500 to the medical branch to support the studies of Ardzroony Packchanian, Ph.D., director of the laboratory of microbiology, on virus transmission in small animals in order to try to devise a rapid diagnosis procedure and to assist in screening tests in therapy.

WASHINGTON

Surgical Society Resumes Activities.—On November 7 the Spokane Surgical Society held its first postwar meeting and voted to hold its usual annual meeting in April. Meetings of the society were suspended during 1942 and 1944 and the spring of 1945.

Pediatric Society Changes Name.—The Seattle Pediatric Society recently changed its name to the Puget Sound Pediatric Society to include in its membership physicians in wider territory than had previously been possible. Officers are Homer T. Clay, Tacoma, president; Walter B. Seelye, Seattle, vice president, and Ward B. Chesley, Seattle, secretary-treasurer.

GENERAL

Orthopsychiatric Meeting.—The American Orthopsychiatric Association will hold its twenty-third meeting at the Hotel New Yorker, February 14-16, under the presidency of Dr. Norvelle C. LaMar, New York. The program has been divided into discussions on Service Problems, Counseling, Treatment of Delinquents, Sociopsychiatric Problems, Group Psychotherapy, Psychoses and Schizophrenia in Childhood, Industrial and Personnel Problems, Psychologic Considerations, Clinical and General Problems and Childhood Emotional Problems.

Robert Page Named Medical Director of Standard Oil Company.—Dr. Robert C. Page, New York, a medical officer in the Army Air Forces during World War II and assistant medical director of the Standard Oil Company of New Jersey, has been appointed general medical director of the company, succeeding Dr. Willard J. Denno, New York, chief medical officer since 1918. Dr. Denno, who developed the company's medical department from an office with one part time physician to a worldwide organization having eleven hospitals and more than 150 physicians and 1,500 nurses and attendants, helped Jersey Standard to become one of the most advanced companies in the field of industrial medicine. He will continue with the company as medical consultant. Dr. Alfred Gage, New York, an assistant medical director, will be in charge of medical service and advice for affiliated companies in Latin America.

Lasker Award Goes to Physicians.—On January 23 the $500 Albert and Mary Lasker Foundation Awards were presented to Dr. Irl C. Riggin, Richmond, Va., health commissioner of Virginia, and Dr. Robert L. Dickinson, New York, gynecologist. The awards are given for the most significant contribution to research in human fertility and for meritorious public health service. According to an announcement Dr. Riggin led Virginia in becoming the seventh state in the union to make planned parenthood services available as part of the state's public health program of maternal care. Dr. Dickinson, as organizer of the National Committee on Maternal Health, has pioneered in fundamental research in the medical aspects of human fertility and its control. The fertility award will be given in honor of the late Dr. Hannah M. Stone, first medical director of the Margaret Sanger Research Bureau, co-author with Abraham Stone of the "Marriage Manual." The public health award will be in honor of Mrs. Margaret Sanger, founder of the birth control movement and at present honorary chairman of the federation.

Resolutions Adopted by Academy of Pediatrics.—At its annual meeting in Detroit, January 15-18, the American Academy of Pediatrics, after careful consideration of proposed legislation in Congress as it relates to child health services, reaffirmed its resolution as adopted at its 1939 session, namely:

> That the American Academy of Pediatrics, regarding the provisions for maternal and child welfare, favors the use of public funds to provide such services to those groups of the population unable to pay for medical services, to the end that the standards of medical care may be maintained at a high level among such groups.

The academy indicated that it does not favor the use of federal funds for those able to provide good medical care from their own sources and directs the attention of those considering proposed legislation to its fact finding study of child health services now in progress, which at its conclusion should assist in the development of sound programs at state levels based on demonstrated needs (The Journal, February 2, p. 298). Pending the completion of this study, it is recognized that urgent needs exist in some states that should be met in the immediate future. To this end the academy recommends that additional federal funds be made available for grants-in-aid to the states under existing maternal and child health and crippled children's programs of title V of the Social Security Act. The academy also listed specific criticisms of S. 1318, citing this for its belief that the maternal and child welfare act of 1945 does not represent the best form of legislation for the purpose for which it was written. At the recent meeting Dr. Lee F. Hill, Des Moines, Iowa, was named president-elect of the academy and Dr. Jay I. Durand, Seattle, was inducted into the presidency. Dr. Clifford G. Grulee, Evanston, was reelected secretary-treasurer.

Appointments to Advisory Cancer Council.—Drs. Robert S. Stone, San Francisco, and Charles B. Huggins, Chicago, have been appointed for three year terms on the National Advisory Cancer Council, succeeding Albert B. Hastings, Ph.D., Boston, and Dr. James B. Murphy, New York, whose terms have expired. Dr. Stone is professor of roentgenology at the University of California Medical School, Berkeley. Dr. Huggins, who is professor of surgery (urology) at the University of Chicago School of Medicine, has just been named professor of urology and head of the department at Johns Hopkins University School of Medicine (The Journal, January 26, p. 231). The National Advisory Cancer Council is composed of six members in addition to the Surgeon General of the U. S. Public Health Service, who is chairman ex officio. It serves as an advisory body to the Surgeon General in the direction of the work of the National Cancer Institute. The law establishing the council provides that two members shall be appointed each year according to the council's membership arrangement. Other council members are Dr. George M. Smith, Pine orchard, Conn., research associate in anatomy, Yale University School of Medicine, New Haven, and medical director, of the Anna Fuller Fund for Cancer Research, executive director of the council; Andrew C. Ivy, professor of physiology, Northwestern University Medical School, Chicago; Frank E. Adair, New York, Memorial Hospital for the Treatment of Cancer and Allied Diseases, and Sherwood Moore, director of the Mallinckrodt Institute of Radiology, Washington University School of Medicine, St. Louis.

New Program on Crippling Diseases Affecting Children.—A nationwide five point program to expand and accelerate its fight against all crippling diseases affecting children will be set into action at once by the Shriners of North America, it was announced in New York recently. The new program has been developed through a series of meetings sponsored by the Shriners' Imperial Council. The five phases of the new plan are:

> The granting of scholarships, to be known as the Fellowships of the Shriners' Hospitals for Crippled Children, in orthopedic surgery to outstanding, qualified medical students. An initial yearly appropriation of $7,500 has been set aside. Three scholarships of $2,500 each will be made in 1946 for training in three universities, soon to be named.
>
> An annual appropriation of $3,750, to be granted for scholarships in orthopedic nursing. These nurses, in turn, will instruct and give encouragement to other nurses interested in specializing in the crippled children's field.
>
> The establishment of a research project to probe further the sources, methods of treatment and prevention of all crippling diseases attacking children.
>
> The expansion of present facilities and equipment of the fifteen Shriners' hospitals now in operation and establishment of new hospitals in other localities.
>
> The establishment of convalescent homes in connection with all Shriners' hospitals as rapidly as possible. The installation of recreational and occupational therapy courses to assure continuing physical improvement and self development after healing has been completed.

The convalescent and occupational therapy plan is already under way at the San Francisco Hospital. The first Shriner Hospital was opened in Shreveport, La., Sept. 16, 1922. In addition to this hospital and the one in San Francisco, other hospitals are located in Minneapolis-St. Paul; Portland, Ore.; St. Louis; Montreal, Canada; Springfield, Mass.; Chicago; Philadelphia; Greenville, S. C.; Honolulu; Spokane, Wash.; Salt Lake City; Winnipeg, Canada; Lexington, Ky., and San Francisco.

CORRECTION

Brig. Gen. Raymond W. Bliss.—In a recent item under Medicine and the War it was erroneously stated that Brig. Gen. Raymond W. Bliss graduated from Harvard Medical School, Boston, in 1910. This should have read Tufts College Medical School, Boston, in 1910.

Deaths

Waller Smith Leathers ⊕ prominent medical educator, died at his home in Nashville, Tenn., January 26, aged 71, of cerebral hemorrhage.

Dr. Leathers was born near Charlottesville, Va., on Dec. 4, 1874. He carried on special studies in biology, geology, mineralogy and chemistry and graduated at the University of Virginia Department of Medicine, Charlottesville, in 1895. A member of the Alpha Omega Alpha, he subsequently received many honorary degrees. He had graduate work at Johns Hopkins University, the University of Chicago, Biological Laboratory in Long Island, N. Y., and the Marine Biological Laboratory, Woods Hole, Mass., as well as at Harvard Medical School. In 1896 Dr. Leathers began his active teaching career as a member of the department of chemistry at the Miller School of Virginia, subsequently going to the University of South Carolina as professor of biology. In 1899 he went to the University of Mississippi as professor of biology, later serving as professor of physiology and professor of physiology and materia medica. In 1903 he assisted in the organization of the medical school at the University of Mississippi, subsequently serving as its dean.

Joining Vanderbilt University School of Medicine, Nashville, in 1924 as professor of preventive medicine and public health, he became associate dean in 1927 and dean the following year, holding this position until June 30, 1945, when he retired. In 1928 he was chosen a member of the university's board of trustees.

Dr. Leathers' intense interest in medical education took him actively into related fields. He was a member of the first Basic Science Board created in Tennessee in 1943, serving as the first president. He also served as chairman of the then new state public health council. In Mississippi he had served the Mississippi State Board of Health, first in 1910 as director of public health and from 1917 to 1924 as director of public health and executive officer and member of the board. He was a member of the National Board of Medical Examiners from 1923 to 1934, serving as president from 1930 to 1934 and was elected a member at large in 1936. He had been a member of the board of scientific directors of the International Health Division of the Rockefeller Foundation from 1930 to 1933 and from 1935 to 1937, serving as a member of the advisory committee on public health of the Commonwealth Fund since 1929 and various terms on the Advisory Health Council of the U. S. Public Health Service and health and medical advisory committee of the American Red Cross.

He served the American Medical Association first in 1911 as a member of the speakers' bureau of the Council on Health and Public Instruction, as a member of the Council on Medical Service and Public Relations when it was created in 1943, resigning April 6, 1945, as secretary of the Section on Preventive Medicine and Public Health from 1920 to 1923, holding the chairmanship the following year, as a member of the House of Delegates from 1923 to 1927, and in 1938 was a member of an advisory committee to the Council on Medical Education and Hospitals.

He was a member of numerous local and national societies, serving for many years as chairman of the committee on professional education of the American Public Health Association, serving as president of the national group in 1940-1941. He was vice president of the American Association for the Advancement of Science in 1928, vice president of the Association of American Medical Colleges in 1938, and president in 1942-1943. He served as secretary of the Section on Public Health of the Southern Medical Association from 1913 to 1917 and as president, 1922-1923.

Dr. Leathers was a man of excellent judgment, of high medical ideals and a leader who inspired confidence.

Carl Ellsworth Black ⊕ Jacksonville, Ill.; Chicago Medical College, 1887; born in Winchester, Ill., July 4, 1862; an Affiliate Fellow of the American Medical Association, of which he had been a member of the House of Delegates in 1904; member of the Western Surgical Association, serving as president in 1930; emeritus member of the Illinois State Medical Society and in 1904 president; president of the Morgan County Medical Society in 1927; fellow and member of the board of governors of the American College of Surgeons; served as surgeon at the Passavant Memorial and Our Saviour's hospitals and of the Chicago and Alton and the Chicago, Burlington and Quincy railroads; in 1944 presented to the Illinois State Medical Society the Carl E. Black Collection of photographs of physicians, which contained more than three thousand photographs, said to be the largest single collection in the country except for that in the office of the Surgeon General of the U. S. Army, and registered in the state museum at Springfield as the Carl E. Black-Illinois State Medical Society Collection; served as president of the Morgan County Historical Society; died January 13, aged 83, of coronary heart disease.

James Joshua Terrill ⊕ Dallas, Texas; University of Texas School of Medicine, Galveston, 1902; born near Armstrong, Mo., Feb. 21, 1877; specialist certified by the American Board of Psychiatry and Neurology, Inc.; since 1943 honorary professor of neuropsychiatry at the Southwestern Medical Foundation; emeritus professor of neuropsychiatry at Baylor University College of Medicine; formerly instructor and professor of pathology at his alma mater; past president of the North Texas Medical Society and the Dallas County Medical Society; formerly secretary of the Galveston County Medical Society; member of the Southern Medical Association; served as visiting pathologist at the John Sealy Hospital and St. Mary's Infirmary; chief of laboratory, Temple Sanitarium in Temple from 1913 to 1917; a medical director of the Timberlawn Sanitarium; died October 10, aged 68, of cardiovascular renal disease and pulmonary tuberculosis.

Larue Depew Carter ⊕ Indianapolis; Medical College of Indiana, Indianapolis, 1904; born in Westfield, Ind., March 17, 1880; professor of neurology and since 1914 a member of the faculty at the Indiana University School of Medicine; specialist certified by the American Board of Psychiatry and Neurology, Inc.; fellow of the American College of Physicians; served during World War I; colonel, medical reserve corps, U. S. Army, not on active duty; in 1945 appointed to the Indiana Council for Mental Health; chief consultant, "Norways" Sterne Memorial Hospital; visiting chief, department of neuropsychiatry, Indianapolis City Hospital; member of the visiting staff, department of neuropsychiatry at the Methodist and St. Vincent's hospitals; formerly on the staff of the Richmond (Ind.) State Hospital; died January 22, aged 65.

Thomas B. Bass ⊕ Abilene, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1890; past president of the Taylor-Jones Counties Medical Society; member and formerly vice president of the American Psychiatric Association and the State Medical Association of Texas; served as president of the Texas Neurological Society; at one time on the staff of the North Texas Hospital for Insane in Terrell; joined the staff of the Abilene State Hospital in 1901 as first assistant physician, becoming superintendent in 1909 and serving in that capacity until 1943; physician for McMurry College; died December 22, aged 80, of chronic myocarditis.

Russell Lee Roy Allen, Daisy, Tenn.; Birmingham Medical College, 1912; member of the American Medical Association; died in Chattanooga October 13, aged 56, of heart disease.

Thomas Smith Armstrong ⊕ McKeesport, Pa.; Jefferson Medical College of Philadelphia, 1903; on the staff of the McKeesport Hospital; died October 3, aged 65, of heart disease.

Emanuel Stratton Black, Williamstown, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1902; member of the American Medical Association; served during World War I; affiliated with the Veterans Administration; died October 3, aged 64, of coronary thrombosis.

Lester Belmont Bradford, Rockland, Maine; Maryland Medical College, Baltimore, 1905; during World War I a medical officer in the zone of advance; went with the Army of Occupation to Coblenz, Germany, where he remained a year after the war; at one time medical commissioner in the Balkans, helping to organize Red Cross hospitals; served on the staffs of various Veterans Administration facilities; died in Tenants Harbor September 24, aged 61, of chronic nephritis and diabetes mellitus.

Alfred H. Bullock ⊕ Cushing, Iowa; Sioux City College of Medicine, 1900; died September 21, aged 71, of paralysis of the respiratory center and uremia.

Robert E. Caldwell, Waterford, Va.; Medical College of Virginia, Richmond, 1898; died in Bay Pines, Fla., October 6, aged 75, of cerebral hemorrhage.

Raymond Smith Cooper ⊕ Syracuse, N. Y.; Syracuse University College of Medicine, 1910; served during World War I; on the staff of the People's Hospital; died October 7, aged 59, of hypertensive heart disease.

Allen Donaldson ⊕ Carrollton, Ky.; University of Louisville Medical Department, 1898; member of the county board of health and the Radiological Society of North America, Inc.; died November 2, aged 68, of chronic myocarditis.

William B. Finney, Kennett, Mo.; St. Louis College of Physicians and Surgeons, 1890; member of the American Medical Association; served as coroner of Dunklin County; died in St. Francis Hospital, Cape Girardeau, October 27, aged 86, of senility.

Jasper Edwin Guernsey ⊕ Tacoma, Wash.; Missouri Medical College, St. Louis, 1895; for four years county coroner in Iowa; served on the staff of the Eastern State Custodial School in Medical Lake; died December 16, aged 76.

William Nelson Harrison, Upper Montclair, N. J.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1895; died October 9, aged 72, of arteriosclerosis.

Walter Lawrence Hearn, Lynn, Mass.; Harvard Medical School, Boston, 1902; member of the American Medical Association; school physician; visiting physician at the Lynn Hospital; died at his summer home in Nahant, September 30, aged 67, of coronary thrombosis.

J. H. Holiman, Dallas, Texas (licensed in Arkansas in 1903); served on the staff of the Pulaski County Hospital in Little Rock, Ark.; died September 15, aged 79, of heart disease.

Ross Holman Jones ⊕ Coudersport, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1901; chairman of the Potter County Draft Board; served during World War I; on the staff of the Coudersport Hospital; died in the Olean (N. Y.) General Hospital October 23, aged 67, of chronic nephritis, uremia and arteriosclerosis.

Fred Warfield Lane ⊕ Cambridge, Ohio; University of Pennsylvania Department of Medicine, Philadelphia, 1893; served during World War I; died in the Veterans Administration Facility, Chillicothe, October 11, aged 72, of arteriosclerosis and hypertension.

Lewis Wayne Law, Minneapolis; Harvard Medical School, Boston, 1943; interned at the Ancker Hospital in St. Paul; also a graduate in dentistry; began active duty as a lieutenant (jg) in the medical corps, U. S. Naval Reserve, on Oct. 10, 1944; released to inactive duty on Aug. 3, 1945; instantly killed by a bolt of lightning August 29, aged 29, while on the golf links in Lake Forest, Ill.

William Warner Meiners, Malverne, N. Y.; University of the City of New York Medical Department, 1891; member of the American Medical Association; for a time coroner in Long Island City; died October 20, aged 90, of chronic endocarditis, arteriosclerosis and coronary embolism.

Andrew John Muller ⊕ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1897; for many years on the staff of the Kensington Dispensary for Treatment of Tuberculosis; died October 31, aged 71, of carcinoma of the liver.

Michael E. O'Brien, Pittsburgh; University of Pennsylvania Department of Medicine, Philadelphia, 1896; member of the American Medical Association; died in St. Francis Hospital October 25, aged 75, of congestive failure.

Herbert Bittner Saylor, Des Moines; Rush Medical College, Chicago, 1908; died September 23, aged 68, of acute pyelonephritis and coronary arteriosclerosis.

Virgil Dural Selleck, Glens Falls, N. Y.; Albany Medical College, 1903; member of the American Medical Association; health officer; on the staff of the Glens Falls Hospital; died October 13, aged 68, of bronchopneumonia and carcinoma of the prostate.

Carl Schurz Tompkins, Randolph, N. Y.; University of Buffalo School of Medicine, 1901; member of the American Medical Association; served during World War I; formerly on the staffs of the City and Buffalo General hospitals in Buffalo, Batavia (N. Y.) Hospital and the Medina (N. Y.) Memorial Hospital; at one time on the faculty of his alma mater; died October 25, aged 73, of edema of the lungs and arteriosclerosis.

Paul Tradelius ⊕ Brooklyn; Long Island College Hospital, Brooklyn, 1904; specialist certified by the American Board of Ophthalmology; member of the Brooklyn Ophthalmological Society; consulting ophthalmologist at the Samaritan Hospital and assistant surgeon at the Brooklyn Eye and Ear Hospital; died in St. Mary's Hospital October 11, aged 71, of carcinoma.

John Alfred White II, Springfield, Pa.; Medico-Chirurgical College of Philadelphia, 1916; decorated with the Military Cross of England; received the Distinguished Service Cross and the Croix de Guerre for services during World War I; chief medical examiner of the Pennsylvania Railroad; died in Baltimore November 16, aged 51, of coronary thrombosis.

Samuel Wolf, Brooklyn; Fordham University School of Medicine, New York, 1919; member of the American Medical Association; died September 13, aged 62.

Charles Albert Yoder, Elm Creek, Neb.; Lincoln Medical College of Cotner University, 1902; served during World War I; died October 9, aged 70, of coronary thrombosis.

DIED WHILE IN MILITARY SERVICE

Morris I. Bierman ⊕ Washington, D. C.; University of Minnesota Medical School, Minneapolis, 1920; born in Minneapolis Dec. 18, 1893; specialist certified by the American Board of Radiology, Inc.; served as assistant surgeon in the U. S. Public Health Service Reserve; on the staffs of the Emergency and Providence hospitals; began active duty as a lieutenant commander in the medical corps of the U. S. Naval Reserve in July 1942; on active duty in the Atlantic early in the war; for a short time stationed at the Naval Hospital at Bainbridge, Md.; for eighteen months had been on duty aboard an LST in the Pacific area; died Sept. 21, 1945, aged 51, of coronary thrombosis.

Joseph Harry Buckman, Albuquerque, N. M.; Northwestern University Medical School, Chicago, 1937; member of the American Medical Association; interned at the Evanston Hospital in Evanston, Ill.; began active duty as a lieutenant in the medical corps, U. S. Naval Reserve, on March 16, 1942; promoted to lieutenant commander; died in the U. S. Naval Hospital, Pensacola, Fla., Sept. 14, 1944, aged 38.

Daniel Joseph Hurley, Newton, Mass.; Harvard Medical School, Boston, 1909; born in Boston Nov. 16, 1881; formerly a member of the state board of registration in medicine; member of the Association of Military Surgeons of the United States; a captain in the medical corps of the U. S. Army at Camp Upton, L. I., and later chief of the surgical staff at Fort Bayard, N. M., during World War I; served on the staff of the Boston City Hospital; once surgeon for the Veterans Administration in Boston; began active duty as a lieutenant colonel in the U. S. Army (National Guard) on Jan. 16, 1941; executive officer of the 101st Regiment of the Twenty-Sixth (Yankee) Division until 1942, when he was named recruiting medical officer at Bangor, Maine; two years later became harbor defense surgeon at Portland, Maine, and since then had been on the staff of the Veterans Administration Facility in Newington, Conn.; died in the Lovell General Hospital, Fort Devens, October 15, aged 63, of coronary embolism.

John Kerr Macmillan Jr., Santa Monica, Calif.; College of Medical Evangelists, Los Angeles, 1938; member of the American Medical Association; diplomate of the National Board of Medical Examiners; interned at the Glendale Sanitarium and Hospital in Glendale; served a residency at the Santa Monica Hospital; began active duty as a first lieutenant in the medical corps, Army of the United States, on Feb. 28, 1944; promoted to captain on Aug. 1, 1945; died in Egypt Oct. 5, 1945, aged 37, of injuries received in an automobile accident.

Jewel Eugene Roberts, Salt Lake City; George Washington University School of Medicine, Washington, D. C., 1938; diplomate of the National Board of Medical Examiners; interned at the New York City Hospital in Welfare Island and the New York City Hospital in New York, where he served a residency; began active duty as a captain in the medical corps, Army of the United States, on July 8, 1942; died in the Station Hospital, Camp Kilmer, N. J., August 16, aged 33, of tsutsugamushi fever.

William Joseph Wagner ⊕ Lieutenant (MC), U. S. Navy, New York; Jefferson Medical College of Philadelphia, 1939; interned at the Roosevelt Hospital; served an internship and residency at St. Vincent's Hospital; commissioned lieutenant (jg) in the medical corps of the U. S. Naval Reserve on June 16, 1942; later entered the medical corps of the regular U. S. Navy in the same rank; promoted to lieutenant; died near Sabine Pass, Texas, September 17, aged 32, of extreme multiple injuries received in an airplane accident.

Harvey Glenn Wible, Monessen, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1935; member of the American Medical Association; interned at the Homeopathic Medical and Surgical Hospital, Pittsburgh; formerly resident at the George F. Geisinger Memorial Hospital in Danville and the Shurly Hospital in Detroit; served on the staff of the Gemmill Hospital; began active duty as a first lieutenant in the medical corps, Army of the United States, on July 1, 1941; assigned to Station Hospital, Edgewood Arsenal, Maryland; later promoted to captain and major; killed in Hondo, Texas, Sept. 1, 1945, aged 35, in an airplane crash.

Public Health in India

The approach of self government for India has emphasized the appalling problem of the public health of that country of 420 million people. Western medical science has been able to touch only the fringe of the problem. India has only 42,000 doctors—one for every 10,000 people; India needs 300,000 doctors. There are only 5,000 trained midwives; 70,000 are necessary. The mass of the people still depend on indigenous medical systems which contribute little to the improvement of the national health, yet they claim and receive from several of the provincial governments privileges and grants grossly inadequate for scientific medicine. In most of India domiciliary treatment of the sick is difficult because of the miserable housing. The hospitals provide only 1 bed for every 3,000 persons. Tribute should be paid to the doctors, Indian as well as British, who have made many important advances in medicine and labored unceasingly to check epidemics and promote hygienic habits.

Indian vital statistics are imperfect, but their story is clear. The recorded death rate is 22 per thousand of population. The infant mortality is 162 per thousand live births. There is an average annual mortality of 145,000 from cholera, 70,000 from smallpox, 31,000 from plague, 290,000 from dysentery, 500,000 from tuberculosis and 3,667,000 from "fevers." The phenomenal increase of population renders the problem of public health more difficult. The Reconstruction Committee of the Viceroy's Council has recognized that a determined and coordinated attack on disease has long been necessary. Its success will depend on corresponding advances in the fields of education, housing and nutrition. A Health Survey and Development Committee, under the chairmanship of Sir Joseph Bhore, has been engaged on its immense task since the cold weather of 1943.

The Rehabilitation of the Medical Libraries of Europe

The Royal Society of Medicine has received from the Rockefeller Foundation $300,000 for setting up and maintaining for four years a Central Medical Library Bureau. The first objective of the bureau is the rehabilitation of medical libraries in the liberated countries, which have suffered so much during the war by German theft or devastation. The second and more permanent objective is the provision of rapid interchange of medical knowledge between individuals and institutions. At the present time the first objective is of paramount importance. Owing to the shortage of paper, means other than the use of printed paper must be considered. During the war the Royal Society of Medicine provided vital information for physicians in the forces overseas by microfilm. This experience will enable the society to perform a similar service in the restoration of medical libraries.

Soldiers Blinded by New Guinea Cherries

At the Liverpool Rotary Club Mr. C. D. Tovell, scientific adviser to the British forces in the Far East, stated that 27 soldiers, now back from fighting in New Guinea, were totally blind as a result of eating what looked like ordinary English cherries. The fruit was discovered at the end of 1942 and its lay name was "finger cherry." It looked and tasted like an English cherry. One or two of these cherries were eaten without ill effects, but soldiers who ate nine or ten became totally blind within a few hours. At present a means of restoring sight has not been found. As soon as the properties of the fruit were discovered, the authorities destroyed as many of the trees as possible.

British War Casualties

In the House of Commons the prime minister gave the total casualties of the armed forces of the British commonwealth and empire from Sept. 3, 1939 to Aug. 14, 1945 (excluding deaths from natural causes) as 1,246,025. This includes all men reported prisoners of war and in the armed forces of the United Kingdom, New Zealand, South Africa and the colonies, all men reported missing during the war. A final statement of casualties will be issued when the fate of those missing is determined and when all prisoners of war are repatriated.

Doctors in France

A. Rosier, general secretary to the Office of University Statistics, has published in the *Médecin français* an article entitled "Do We Have Too Many Doctors?" For years this question has been unanswered. Since 1932 the Office of University Statistics has attempted to ascertain the optimum number of doctors and the localities needing them. Before the war it supplied information to young doctors regarding the distribution of doctors in France and provided a fund for loans to young doctors with inadequate means. During and shortly after the war the situation became disorganized. Numerous doctors were prisoners in Germany, others had left the devastated areas. Now the situation is becoming more normal again. There has been an appreciable increase in the number of first year students in the faculties of medicine, increasing from 2,071 in 1939 to 2,500 in 1944-1945. For the scholastic year 1945-1946 there has been a great influx of young people in the faculties of medicine because of the return of those deported, the demobilization and the abolition of racial laws. Notwithstanding this steady increase of students, the number of diplomas granted each year remains almost the same: 1,229 in 1900, 1,297 in 1932, 1,251 in 1944. However, 5 per cent of those who receive the diploma do not practice medicine. This year the number of graduates will increase, as in the period subsequent to the war of 1914-1918.

In spite of the constant number of students graduating each year there has been a constant increase in the number of practicing physicians from 15,907 in 1900 to about 27,000 in 1945. This increase is due to a yearly excess in the number of new doctors over those retiring or dying. This surplus was (on an average) about 219 doctors for the period 1910-1920 and 280 for 1920-1945. Rosier remarks that if these conditions continue France will have 3,000 more doctors in ten years. This increase is desirable because of the constant progress of medicine and the increased specialization of doctors, which gives them numerous openings.

In 1900 there was 1 doctor for every 2,445 inhabitants and there is now 1 doctor for 1,450; in several countries of Europe there is 1 doctor for 900 to 1,000 inhabitants. This distribution is very irregular in France. In Paris, Lyons, Toulouse and other important cities there is 1 doctor for 600 to 700 inhabitants; they are overworked and worn out. In numerous industrial centers or devastated areas there is 1 doctor for 3,000 to 4,000 inhabitants. In some places there is an entire absence of doctors. There is need for doctors in the French colonies and for medical inspectors in various institutions. The part time services of a doctor in every concern employing over 50 workmen is being considered as well as a full time doctor in every factory employing 2,000 to 2,500 workers.

Rosier concludes that a surplus of doctors does not exist but, on the contrary, there is need for more doctors and, above all, there is poor distribution of those available. He proposes that the state assist students with inadequate means, asking them, as compensation, to bind themselves to practice in less desirable districts for five or ten years.

Clitocybine, a New Antibacterial Substance

At the meeting of the Academy of Science held in September Prof. A. Charles Hollande presented a memorandum on a new antibacterial substance which he calls clitocybine. This product is extracted from Clitocybe gigantea, a large mushroom of the Agaricus family (Aspropaxillus). The author remarked that on alpine meadows of an altitude between 900 and 1,400 meters the grass around this mushroom does not develop, some dying without putrifying. On observing this he presumed that there was an active principle which inhibited the multiplication of microbes necessary for the putrefaction of vegetable tissues. This mushroom when cooked is edible, but when raw and dried it contains toxic substances. Clitocybine is soluble in water, chloroform, acetone and sulphuric ether; 0.005 cc. of a solution obtained after ether extraction and concentration in water prevents the development of the tubercle bacillus under certain specified conditions. To inhibit under the same conditions cultures of staphylococci, 0.025 cc. of the same solution is necessary. The inhibitory power of clitocybine is present also against Escherichia coli, Eberthella typhosa and Pseudomonas aeruginosa, against which penicillin is not effective. Repeated subcutaneous injections of tuberculous guinea pigs showed the massive lysis and disappearance of virulent tubercle bacilli.

Miscellaneous

At the reopening of the Paris University, 37 foreign scientists were elected doctors "honoris causa"; among those were Wesley C. Mitchell of Columbia University, W. T. Longcope of Baltimore, C. H. Best of Toronto, Horatio E. Smith of Columbia University, posthumously Edward K. Rand of Harvard University, Sir Alexander Fleming of London and Joffe of Moscow.

At its latest meeting the Academy of Medicine elected as foreign associated members E. D. Adrian of Cambridge, Sir Henry Dale of Picadilly, Sir Alexander Fleming of London, B. Houssay of Buenos Aires, George R. Minot of Boston, Theodore H. Morgan of San Francisco, L. A. Orbeli of Russia, Miguel Ozario de Almeida of Rio de Janeiro, Charles H. Best of Toronto and Ross G. Harrison of Washington.

ITALY

(From Our Regular Correspondent)

FLORENCE, Nov. 30, 1945.

Fractures of the Extremities

Dr. Pietre Franceschini, military surgeon serving at the front and in territorial hospitals near the front for the last four years, recently delivered a lecture to the Accademia Medico Fisica of Florence. He reported the results obtained in the therapy of fractures of the extremities, either simple (236 cases) or compound (1,256 cases). He obtained good results with either Bayer-Ombredanne's bandage or the classic posterior traction by means of Delbet's bandages in 125 cases of fracture of the clavicle. There were 17 cases of simple fracture of the shoulder. One soldier in this group had a fracture of the greater humeral tuberosity. The fractured fragment contained the greater tuberosity and a portion of the humeral head. Local anesthesia was applied, and the arm was put in abduction of 90 degrees and was immobilized for forty days in a Böhler splint, after which careful active mobilization was performed. Good results were obtained in other cases from abduction of the arm at 100 degrees with the elbow in extension.

There were 15 cases of noncomminuted diaphysial fractures of the femur. Immobilization with traction was carried out as soon as possible. Traction was obtained either by the Tillaux-Delbet technic with the Kirmisson pulley or by the Böhler technic with a nail in the tibia for transskeletal traction. The leg was placed in normal position on a double inclined plane. Immobilization with plaster cast was applied at the second stage of the operation. This method proved to be of great value. It produces gradual reduction of the fracture with a relatively small force of traction. Pain rapidly diminished. The clinical picture of gas embolism was never observed when this therapy was applied.

In the majority of cases the fractures were due to fragments of grenades or to shells from mortars and were more or less macerated. Primary definitive therapy in the fighting zones was never completed with a primary suture. Any of the following procedures were resorted to: capillary drainage, manual reduction of the fracture and application of a closed cast. Rational immobilization followed. Transskeletal traction was applied to the fracture in 18 cases for a period which varied from fifteen to forty days. Generally speaking, the wounded who were treated with this technic were able to be transported to hospitals far to the rear within ten or fifteen days. The mortality from compound fractures in the posts near the fighting zones was 2.5 per cent. In a group of 236 soldiers with war fractures treated in territorial hospitals, the great majority had been wounded one or two months before arriving at the hospital.

Medical Journals

The *Giornale di Medicina Militare*, which had been published for ninety-two years by the General Department of Military Sanitation, discontinued publication in June 1943. Now it has reappeared. Other medical journals which reappeared after the war are *Experimentale, Archivio di Biologia Normale e Pathologica, Ricerca Scientifica e Ricostruzione, Annali di Medicina Navale* and *Rivista Italiana di Igiene*. Dr. Alessandrini of the Pisa University was appointed editor of the *Rivista Italiana di Igiene* to succeed Dr. Filippe Neri, its previous editor, who died in the Instituto di Igiene of the Bologna University during an aerial attack.

Personal Items

Dr. Siro Fadda was recently appointed surgeon general in Italy. After his appointment he sent a message of salutation to all the members in the medical military service asking for their collaboration in reorganizing postwar military medicine and sanitation.

Colonel Dr. Guido Ferri was recently appointed chief of the School of Military Sanitation in Florence.

The Military Institute of Chemistry and Pharmacy, which was closed because of great destruction and pillage by the Germans, was recently reopened. Every effort is being made to reestablish the departments in which drugs and material for the army are prepared. Col. Giuseppe Scotti was appointed head of the institute.

Deaths

Dr. Giulio Chiarugi died on March 7, 1944. He was born in Siena on Jan. 28, 1859. He obtained the degree of Doctor of Medicine from the University of Turin in 1883. He was appointed regular teacher of anatomy on the Faculty of Medicine of the University of Siena in 1888 and held the same position on the Faculty of Medicine of the University of Florence for forty-one years. He published several books, among them a volume on general anatomy and a textbook on human anatomy which is in its sixth revised edition. He also wrote a textbook on embryology and published articles on the relation between the form of the cranium and the brain and on the structure of bone tissue and the histogenesis of muscular fibrous cells of the heart. Several of Dr. Chiarugi's pupils are now teachers of anatomy and related subjects in Italian universities.

BRAZIL

(From Our Regular Correspondent)

Rio de Janeiro, Dec. 24, 1945.

Specific Rheumatic Fever

Dr. A. Penna de Azevedo, pathologist at the Oswaldo Cruz Institute, has reported a study on the incidence of rheumatic fever in Rio de Janeiro. Without an exact method of diagnosis, several criteria have been employed to ascertain the incidence of the disease. Rheumatic fever produces peculiar and characteristic lesions (Aschoff's nodules) generally associated with characteristic changes in the endocardium (rheumatic endocarditis) which permit better and surer criteria for the recognition of rheumatic fever than the clinical signs. The lesions can be recognized only by pathologic examination of the material, in the majority of instances taken during the performance of necropsies. Dr. Azevedo examined records of 6,700 necropsies accumulated in the files of the division of pathology of the Oswaldo Cruz Institute. By the examination of these records the author looked in some cases for the presence of the characteristic histologic lesion and in the majority of cases for changes in the myocardium, with the exception of those in which there was anatomic suspicion or certainty of syphilis. The incidence rate he found should be considered as the minimum incidence, because among other causes of error is the exclusion of the cases of bacterial endocarditis, which in about 75 per cent of the cases occurs in cardiac valves previously affected by rheumatism.

Of the total of 6,700 necropsies there were 589 cases of endocarditis, which was the cause of death of 8.82 per cent of the patients. According to etiology 417 cases of endocarditis were found to be rheumatic (6.22 per cent of the total necropsies), 106 cases syphilitic (1.58 per cent) and 66 cases malignant or bacterial (0.98 per cent). The 417 cases of rheumatic endocarditis (70.79 per cent of all cases of endocarditis) are distributed as 396 cases of valvular endocarditis (94.96 per cent) and 21 cases of mural endocarditis (5.04 per cent). Of the 417 cases of rheumatic endocarditis there were 247 in males (59.23 per cent) and 170 in females (40.77 per cent); there were 209 in white persons (50.12 per cent) and 208 in colored (49.88 per cent); there were 341 cases in Brazilian born persons (81.77 per cent) and 76 in foreign born (18.23 per cent). In the age distribution of 373 cases of rheumatic endocarditis it is significant to note that from ages 20-29 years there were 64 cases (17.16 per cent), 30-39 years 79 cases (21.18 per cent), 40-49 years 58 cases (15.55 per cent) and 50-59 years 57 cases (15.28 per cent), with 20 per cent of the cases occurring over the age of 60 years.

Courses and Lectures

Dr. Oswaldo Camargo, who recently returned from the United States, read a paper at the Hospital de Psiquiatria Infantil (a children's psychiatric hospital) presenting the modern features of psychiatric medical care in the United States.

Dr. Cyro de Rezende, associate professor of ophthalmology at the University of São Paulo, is now giving a special course of lectures and practical demonstrations on ocular neurology.

The University of São Paulo has announced two special courses in psychiatry to be given during the summer session (January and February) by Dr. Annibal Silveira, associate professor of psychiatry, and Drs. Darcy M. Uchoa and Paulo Lentino, physicians of the Juquery Psychiatric Hospital. Both these courses will be given at the Sanatorio Esperança.

Dr. Franklin de Moura Campos, professor of physiology at the University of São Paulo, recently read three papers in the auditorium of the medical department of the Food Relief Service of the Ministry of Labor in Rio de Janeiro. The first one was on the deficiency of certain special proteins, the second on special subjects of the physiopathology of nutrition and the third on the nutritive value of several foodstuffs peculiar to northern Brazil.

Brief Items

The second Pan American Congress of Ophthalmology, recently held in Montevideo, Uruguay, awarded a prize medal and an honor diploma to the administration of the city of Rio de Janeiro because of the distinguished services rendered by the Department of Hospitals in the field of ophthalmology. Dr. Joaquim Vidal, the representative of the department at the meeting, accepted the medal and the diploma.

The São Paulo chapter of the Brazilian Red Cross has opened a child welfare clinic in the city of São Paulo. The clinic is well organized and is provided with the best equipment.

The Rio de Janeiro Medical and Surgical Society recently commemorated its fifty-ninth anniversary. At a special meeting under the chairmanship of Dr. Joaquim Motta the society awarded several prize medals in commendation of the presentation of noteworthy papers on subjects of medicine and surgery. The prizes were awarded to Drs. A. Campos de Paz Filho, Americo Valerio and Aurelio Monteiro, who presented papers respectively on tubal sterility, vitamin A in the diet of air pilots and the Sloane technic in the treatment of feminine genital prolapse.

Personal

A telegram from Washington announced the arrival in that city of Dr. F. Godoy Moreira, orthopedic surgeon of São Paulo, who went to the United States as a guest of the State Department. Dr. Moreira will be present at the meeting of orthopedic surgeons in January 1946.

Dr. Charles Wagley, head of the Division of Health Education of the Special Service of Public Health, resigned this post and left for the United States to resume his work as professor at Columbia University. Dr. Wagley will continue to be associated with the SESP as a technical adviser.

Dr. J. Vieira Filho, who had been an active dermatologist at the Beneficencia Portugueza Hospital of this city, died at the age of 68. Although a Brazilian citizen, Dr. Vieira Filho graduated in medicine from the University of Porto, Portugal, and had worked for some time in Paris, France. He wrote several papers on subjects of dermatology and leprology.

Marriages

Francis Curie Skilling, Key Field, Miss., to Leona Marie Mazzoni, Lieut., Nurse Corps, Army of the United States, at Drums, Pa., December 3.

Robert E. McAlpine, Portsmouth, Va., to Miss Elizabeth Overton of Martinsville at Charlottesville, November 24.

Allie McLeod Stanton, Sylacauga, Ala., to Miss Margaret Elizabeth Spires of Edenton, N. C., December 14.

Thomas Joseph Sheehy Jr., Augusta, Maine, to Dr. Adelaide Therese Scanlon of New York recently.

Robert Nerces Armen, Ithaca, N. Y., to Miss Eleanor Beatrice Baxter at Danville, Calif., November 4.

Sue Hurst Thompson, Hudson, N. Y., to Mr. Edward Henry Gould of New York, November 3.

Frank A. Benchik, East Chicago, Ind., to Miss Audrey Toussaint of St. Louis, November 19.

Walter E. Nawrocki, Cle Elum, Wash., to Miss Helen W. Zbikowski in Bristol, Conn., recently.

Glea V. Stanton, Limestone, Tenn., to Miss Mildred Kathleen Cox in Newport recently.

Cliff Ratliff Jr., Morven, N. C., to Miss Helen Jane Shaffer in Aberdeen, December 3.

James Louie Smith, Magnolia, Ark., to Miss Dede Dabbs of Gulfport, Miss., October 25.

Caryl Potter Jr. to Mrs. Patricia Blakeslee Davison, both of New York, October 11.

Henry P. Royster, Philadelphia, to Miss Ethel R. Fisher of Reedsville, Pa., recently.

Eugene J. Boyd, Iowa City, to Miss Mabel Pullman of Centerville, October 13.

Correspondence

RELATION OF MENSTRUAL TOXIN TO ECLAMPSIA

To the Editor:—That you considered our investigations on menstrual toxin in relation to preeclampsia and eclampsia worthy of comment (THE JOURNAL, Nov. 17, 1945, p. 805) is gratifying. The title, "Menkin's Antinecrosin (Eclampsia Antitoxin)," is misleading. Dr. Menkin has demonstrated no antitoxic activity in antinecrosin serum. The fact that the serum of rabbits injected repeatedly with canine necrosin gives positive precipitin tests against this material (*Proc. Soc. Exper. Biol. & Med.* **56**:217 [June] 1944) is of no significance in this connection, since there is no preparation of necrosin free of other proteins. It was shown to Dr. Menkin in this laboratory that canine necrosin antiserum has as high a precipitin titer against normal dog serum as it has against canine necrosin. We had previously found (*Proc. Soc. Exper. Biol & Med.* **44**:100 [May] 1940; **55**:285 [April] 1944) that rats and rabbits could be made resistant to the toxicity of menstrual discharge and that transferable immunity was demonstrable. Such immune serum, however, could not be used in human beings because, our preparations of menstrual toxin being also mixtures of proteins, there would be the danger of reactions from antibodies to human proteins other than the toxic factor. Because we suspected that Menkin's pleural exudates and menstrual discharge contained the same toxic component, we had hopes that antiserum to necrosin of canine origin might have therapeutic possibilities against menstrual toxin without introducing this danger. Unfortunately, as pointed out in our publication (an item overlooked in the editorial), although menstrual toxin antiserum prolonged the survival time of rats given a minimal lethal dose of either menstrual toxin or canine necrosin, we were unable to get consistent results in attempts to demonstrate similar protective action with necrosin antiserum. The editorial wrongly suggests that it, as well as menstrual toxin antiserum, was effective against multilethal doses of toxin.

The principal value of necrosin antiserum proved to be that it provided a means, by cross precipitin tests, of establishing the fact that menstrual toxin and necrosin contained an identical protein and of demonstrating the presence of this same protein in the circulating blood of menstruating and toxemic women. Furthermore, these findings strengthened our hypothesis that the toxic protein might be a product of tissue damage in general and not just a "specific autolytic product of endometrial cells." We did not, as erroneously intimated in the editorial, demonstrate any higher precipitin titer in eclampsia than during menstruation, although we did find a greater concentration of fibrinolytic enzyme in preeclamptic and eclamptic serum.

The most promising lead from a therapeutic aspect lies in our finding of a protective substance against the "toxin" in the pseudoglobulin fractions of the human pleural exudates that we have tested and of the venous serum of menstruating or eclamptic patients. Such preparations consistently prolong the survival time of rats given a minimal lethal dose of menstrual toxin and often completely prevent death. They have the added advantage of being derived *directly* from human material and should therefore be comparatively safe to administer to human beings. We are at present attempting to prepare a concentrate of such material from which all elements of danger are removed.

O. WATKINS SMITH, PH.D.
GEORGE V. SMITH, M.D.,
Fearing Research Laboratory,
Free Hospital for Women,
Brookline, Mass.

RECURRENT HEADACHE IN MALARIA

To the Editor:—In the January 5 issue of THE JOURNAL Comdr. Frederick A. Butler (MC), U.S.N., takes issue with some of my statements in the report on Recurrent Headache Resultant from Malarial (THE JOURNAL, Oct. 27, 1945, p. 612). There was nothing in my report which implied any danger or likelihood of a significant outbreak or increase of malaria in the United States. It simply stressed that quiescent and recurrent cases of malaria will be encountered more frequently as more men who were stationed during part of their duty on malarious islands return from the Pacific area. This is to be expected, for we know that neither atabrine nor quinine cures the disease; they only suppress it.

We know further that recurrent attacks of malaria are often precipitated by acute infections, exhaustion, malnutrition and alcoholism. Recurrent headache is usually the first and most distressing symptom to usher in an attack of malaria.

The main point of my report was only to emphasize that malaria is a "great imitator" and should be included with greater frequency in the differential diagnosis of recurrent headache.

In our experience on Guam we found the provocative measure of the administration of 15 grains (1 Gm.) of quinine or ephedrine 2 minums (0.12 cc.) subcutaneously surprisingly helpful in establishing the diagnosis of malaria when smears were negative previously. It is not assumed that those who did not respond to the provocative test did not have malaria, no more than it can be assumed that a negative blood Wassermann reaction rules out syphilis.

ABRAHAM KAPLAN, Captain (MC), U.S.N.R.

Bureau of Investigation

SOME MISCELLANEOUS MEDICAL FRAUDS

A Variety of Schemes Debarred from the Mails

Fraud orders issued by the Post Office Department have frequently been the subject of extensive articles by the Bureau of Investigation in these pages of THE JOURNAL. Following are brief abstracts of some fraud orders *not* dealt with previously:

Salvar Medicine Company.—This St. Louis concern is said to have been started in June 1906 by a Charles E. Gallagher, a civil engineer, who previously had run a "patent medicine" outfit in Kansas City, Mo., selling a nostrum called "Alkano." In 1908, it is reported, the St. Louis firm took the name "Salvar Medicine Company of Arizona" and established agencies in various cities. Around 1921, it appears, an Edward L. Eggers joined the business as "medical director," and became the proprietor in 1923. According to the records, he was licensed to practice medicine in Missouri in 1900 and was said to have claimed graduation from the *St. Louis College of Physicians and Surgeons.* This institution was involved in the "diploma mill" scandal of 1923 and 1924, and its charter was revoked in 1927. A John E. Eggers, said to be a brother of Edward L. Eggers, is reported to run the Newell Pharmacal Company of St. Louis and Clayton, Mo., which puts out another nostrum, "Tobacco Redeemer." Through the mails the Salvar concern, sometimes known as the Gallagher Medicine Company, sold its "Salvar" and, for a time, boldly claimed. "Salvar Remedy will cure syphilis perfectly, positively and permanently in any stage of the disease, even though the bones themselves are rotten." It was also promoted for rheumatism, chronic constipation, catarrh, malaria, diseases of the liver, kidneys and bladder, female disorders, tuberculosis, heart ailments, and some other things. Finally the Post Office Department caught up with this quackery and, after due investigation, notified the promoters to show cause why a fraud order should not be issued against them. In reply, Edward L. Eggers denied having made "false or fraudulent representations or promises," and declared that he had discontinued the sale of Salvar and the practice of medicine by mail, had "closed up" his business and accordingly urged that no fraud order be issued against him. Neither he nor anyone representing him, however, attended the hearing of the case, held in Washington on August 9, 1943. At that time a government chemist testified that his analysis of the Salvar specimen purchased from the company by mail showed it to be a solution consisting of water and 30.2 per cent of alcohol, the rest being essentially berberine, acid chloroform extract, cascara, tannin, invert sugar, podophyllum, guaiac, echinacea (or bloodroot, or both), iodine, spearmint, sarsaparilla, possibly eucalyptus, and traces of mineral matter. An expert medical witness testified for the government that he was familiar with all these ingredients and their effects; that the chief action of the mixture would be laxative because of the podophyllum and cascara present, and that the only other drug worth mentioning was iodine, and the amount present was insufficient to constitute a therapeutic dose. He further pointed out that the diet and hygiene suggestions sent out with the nostrum were irrelevant, and showed the worthlessness of Salvar in syphilis and the other disorders mentioned. A fraud order accordingly was issued on Nov. 23, 1943, against the Salvar Medicine Company and Edward L. Eggers.

Natural Health Institute.—This enterprise was conducted at Rocky Mount, N. C., by a "Dr." J. Lewis Clinton, a chiropractor and author of so-called health writings. Further, he published two booklets, "Radiant Health Through Normal Elimination" (27 pages) and "Energy Unlimited" (58 pages). These were advertised by means of a circular entitled "Your Health!" The Post Office Department charged that these booklets were misleading and that the sale of them through the mails constituted a fraud on the public. Clinton, however, was given opportunity to appear at a hearing and show cause why a fraud order should not be issued debarring his business from the mails. A Senior Medical Officer for the Food and Drug Administration who appeared as a witness for the government at the hearing testified as to the factors causing constipation, which condition was the subject chiefly dealt with in the first-named booklet. He pointed out that Clinton's pre-sale allegations that his advice would enable patrons to "free" themselves from enemas, laxatives and other "adjuncts" contrasted with his suggestion in the book that if the methods he advocated (going to stool preferably after breakfast and massaging the lower part of one's abdomen in a certain way) failed to work, a mild laxative should be employed or a soapsuds enema used. It was further pointed out that though his pre-sale representation was that "no dieting" and "no exercises" would be required, both dietary suggestions and exercises are included in his book. The witness further showed that different cases of constipation require varying methods of treatment. As to the book "Energy Unlimited," the leaflet advertising it called it "one of the biggest surprises in the health book field, and utterly unlike anything you have ever read," in which "Dr. Clinton presents conclusive evidence to show that chronic fatigue, nervousness, sleeplessness and associated symptoms of nerve exhaustion are not due so much to a lack of energy itself, but to a lack of proper transmission and expression of energy . . . to tensions and 'short-circuits' which squeeze the nerves and decrease the flow of energy. . . ." The government's expert medical witness testified that the symptoms mentioned above are those of practically all diseases; that Clinton's theory of nerve pressure was a distorted one, and that the diet prescribed in his book for the purpose of forming an alkaline balance in the system is diametrically opposed to that of taking exercise (which Clinton also advocated), since exercise tends to produce an acid condition as opposed to the alkaline-forming diet. Although Clinton did not appear at the hearing, he filed an answer to the foregoing testimony, in which, however, he offered no evidence of the efficacy of the measures recommended in the two booklets mentioned. He did deny any intention to defraud. Nevertheless, the Post Office Department held that the charges against him were entirely sustained by the evidence, and recommended a fraud order debarring him from the mails. This was issued August 14, 1944, against the Natural Health Institute, "Your Health!", "Dr." J. Lewis Clinton, editor and publisher, and W. M. Vandiford, publications department, as well as their officers and agents.

Mary Ries Melendy Ostine Company.—This concern, whose address was Stillwater, Minn., apparently was an outgrowth of the business that was started years ago in Chicago by Mary Ries Melendy, M.D., a homeopathic physician who died in 1927. Some time thereafter the business seems to have been transferred to Stillwater, Minn., by her son, Charles E. Ries. After an investigation, the Post Office Department notified the company and Charles E. Ries, Distributor, to show cause why a fraud order should not be issued against them. Ries did not appear at the hearing of the case held in Washington, but filed a written answer in which he claimed to be a registered pharmacist but for seventeen years engaged in selling through the mails certain homeopathic remedies made in accordance with prescriptions of his mother, who had sold them to her patients for about fifty years. A chemist and a microanalyst of the Food and Drug Administration testified for the government at the hearing, showing that "Dr. Melendy's Brain and Nerve Food" consisted essentially of 98.6 per cent of milk sugar, with traces of calcium, iron, sulfate and phosphate; that "Balm Palmetto Female Tonic" was 99.5 per cent milk sugar, and the remainder moisture and traces of iron, calcium, phosphate, possibly magnesium and minute traces of other minerals. The "Balm Palmetto Capsules" were reported to consist of some greasy material with an odor of cocoa butter, in which was a small amount of plant material, including hydrastis, together with ½ grain of iodine per capsule, combined probably as a sodium salt, and perhaps some saw palmetto, and the "Balm Palmetto Cerate" was found to be a yellowish ointment consisting of 98.2 per cent of petrolatum and 1.8 per cent of moisture. These witnesses further testified that "No. 1 Tokoine" was a mixture of coarsely ground herbs, chiefly coltsfoot leaves, with much smaller amounts of catnip herb, black snakeroot and an unidentified leaf, and that "No. 2 Tokoine" consisted of very finely ground lobelia herb. The Tokoine combination was represented to eliminate pain in childbirth. "Tri-Cura," for rectal disorders, was shown to consist of capsules apparently containing cocoa butter, a small amount of plant material, including hydrastis, and a trace of iodine. "Ostine No. 1," which a pamphlet declared was a "cure" for various disorders in children, was, the witnesses reported, a white powder consisting essentially of 98.4 per cent of milk sugar, with traces of calcium and insoluble material, probably silica, whereas "Ostine No. 2" for "developing" growing children, was found on analysis to be a white powder containing about 98.7 per cent of milk sugar, with traces of calcium, iron and phosphate. An expert medical witness for the government testified as to the worthlessness of these various nostrums in the conditions for which they were advertised, and the business was declared by the Post Office Department to be a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises. Accordingly, a fraud order was issued on Oct. 23, 1944, against the Mary Ries Melendy Ostine Company, Charles E. Ries, Distributor, and Charles E. Ries, the individual.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Osteopaths: Rights Under E. M. I. C. Program.—An act of Congress, chapter 221, Public Law 135, known as "Labor-Federal Security Appropriations Act, 1944" under the subtitle "Maternal and Child Welfare" provided for the grant of money to states for emergency maternity and infant care for the wives and infants of certain enlisted men and aviation cadets in the armed forces of the United States. The use of federal funds received by any state was made subject to the following restriction:

> . . . Provided, That no part of any appropriation contained in this title shall be used to promulgate or carry out any instruction, order or regulation relating to the care of obstetrical cases which discriminates between persons licensed under state law to practice obstetrics: Provided, further, That the foregoing proviso shall not be so construed as to prevent any patient from having the services of any practitioner of her own choice, paid for out of this fund, so long as state laws are complied with.

In both Wisconsin and Texas the plans submitted by the state board of health and subsequently approved by the Children's Bureau eliminated osteopaths from receiving payment for services out of funds made available for the E. M. I. C. program by requiring that the physicians furnishing the services be graduates of a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association. In Wisconsin the osteopaths protested by filing an action asking for a declaratory judgment as to the validity of the state plan. From an order overruling the defendants' demurrer, the state board of health appealed to the Supreme Court of Wisconsin. In Texas, a few months later, the osteopaths filed suit for an injunction to restrain the state board of health from operating under its plan until it had been so amended as to permit osteopaths to participate. From a judgment for the plaintiffs, the defendant appealed to the court of civil appeals, Austin, Texas.

In Wisconsin the state board of health demurred on the ground that the complaint did not state a proper case for declaratory relief. The Supreme Court said that the allegations were

> solely concerned with the proper distribution of federal funds by a federal administrative board, through the Wisconsin state board of health acting as its agent. The several appropriations made by Congress to carry out the E. M. I. C. program were all made to the United States Department of Labor, Children's Bureau, which bureau allots the funds to the several states to carry out the program according to plans approved by the federal bureau. That puts this controversy out of our reach. No facts are alleged in the complaint to the effect that any osteopath has been deprived of the right to practice obstetrics or that any such action has been threatened. Neither is any declaration demanded along this direction. The pleadings, therefore, state no cause of action for declaratory relief on this point. . . .

Accordingly the judgment in favor of the osteopaths was reversed and an order entered sustaining the defendant's demurrer.

In Texas the state board of health contended that the state courts lost jurisdiction of this case because of the rule that

> In the absence of Congressional sanction, state courts cannot entertain suits against the United States or its agencies, including corporations created by the national government, and are without jurisdiction to control or restrain the official conduct of federal officers or agents, federal courts having exclusive jurisdiction over such suits. (21 C. J. S. 796.)

This appropriation act, said the court of appeals of Texas, does not sanction or authorize state courts to entertain suits with respect to any matter arising thereunder. Under such appropriation act the members of the state board of health are not acting as state officials but merely as the agency of the federal government through which the appropriation is to be expended. The act does not authorize the members of the state board of health to receive or administer any portion of the funds appropriated and allotted to Texas, the court continued, except under a plan approved by the chief of the Children's Bureau. The record in this case showed that the Children's Bureau in fact outlined the plan for the administration of the fund allotted to Texas and approved such plan as required by the act. Neither the act nor any Texas statutes undertake to authorize the members of the state board of health to act in any manner except as an agency of the federal government in administering the federal fund appropriated by the Congress to aid in the care of wives and infants of certain enlisted men The court then quoted with approval the statement quoted from the Wisconsin decision and in reference to such quotation said that

> The foregoing quotation from the Hecker case overruled the contention of appellees that the Congress under the appropriation act in question, leaves the development and setting up of the plan for the disbursement of the funds wholly to the state health agencies The Act provides that the state health agencies must adopt rules for the distribution of the funds, and who may participate in care of the wives and infants of soldiers and sailors but expressly provides that such rules and plans must be approved by the Children's Bureau at Washington, and, as was said in the Hecker case, 'it was the approval of the plan by the federal bureau that gave the E M I C program its vitality "

Accordingly the judgment in favor of the osteopaths was reversed and the injunction dissolved—*Hecker v Gunderson, 15 N. W (2d) 788 (Wis, 1944), State Board of Health v Wilson, 188 S W (2d) 999 (Texas, 1945)*

Constitutionality of Illinois Medical Practice Act Sustained.—An information in four counts charging violation of the medical practice act was filed against the defendant From a judgment of guilty he appealed to the Supreme Court of Illinois

The only errors assigned related to the constitutionality of the medical practice act, the defendant's first argument being that the medical practice act violates section 13 of article IV of the constitution of the state of Illinois in that it embraces more than one subject The title of the act is "An Act to revise the law in relation to the practice of the treatment of human ailments for the better protection of the public health and to prescribe penalties for the violation thereof" It is urged that the sections of the act which regulate the practice of midwifery deal with a subject other than the "treatment of human ailments for the better protection of the public health" It is universally recognized, said the Supreme Court, that insanitary and improper methods employed by those engaged in the practice of midwifery are often followed with serious results to the health of the mother and child The regulations provided in the act are for the protection of health and within the title of the act The constitutional question pleaded does not furnish the semblance of a debatable issue

The defendant next argued that the medical practice act violates the due process clause of the constitution in that it forbids the doing of certain things which are not the subject of regulation The defendant referred to section 2 of the act providing that no person shall engage in the practice of medicine or midwifery without being licensed as provided by statute Emphasis is placed on the designation "no person" and it is urged that such an all inclusive term prohibits any one not licensed from ministering simple home remedies to minor ailments Section 2, said the court, must be considered in the light of the other sections and the purposes sought to be accomplished by the whole enactment When so considered the contention made appears frivolous The defendant was convicted for a violation of section 24, which specifies the elements of the offense, a part of which is a holding out to the public as being engaged in diagnosis or treatment of ailments of human beings, suggesting, recommending or prescribing treatment for relief of ailments, all with the intention of receiving directly or indirectly a fee or reward therefor It is clear, the court concluded, that the act is not subject to the criticism directed against it

Finally the defendant argued that the act is vague and meaningless and directs an administrative board to do certain things without furnishing a standard for its guidance The court's attention was directed to that part of section 3 which provides that no person, subject to certain exceptions, shall hereafter receive a license unless he shall pass an examination, etc, satisfactory to the department, and to section 4, which requires each applicant for license to submit certain proof under oath "satisfactorily to the Department" The court said that not only had the validity of the medical practice act been sustained against attack from various angles in prior decisions but objections similar to those made by defendant had been decided adversely to his contention in a number of prior cases (citing them) Accordingly the Supreme Court affirmed the judgment of guilty —*People v Zimmerman, 63 N E (2d) 850 (Ill, 1945)*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1936 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Two Different Types of Posttraumatic Neuroses. A. Adler.—p. 237.
Incidence of Nail Biting Among Adults. L. A. Pennington.—p. 241.
Fraternity in Combat. D. E. Johnson and J. T. Thickstun.—p. 245.
Young Delinquent. Doris Chaplin.—p. 257.
Psychoses Among Women Government Workers in Wartime. H. Stevens.—p. 260.

Sociologic Factors in Neurosis.—Lemkau and Kent review 968 cases admitted to an army neurosis center. They found that normal homes produce a significantly smaller proportion of military delinquents than broken homes. While there is an apparent tendency for the homes with inadequate finances to produce a larger proportion of military delinquents, this is statistically not significant. Patients with an urban background are somewhat more likely to be military delinquents than those of rural background. Military delinquency is not significantly related to marital status in this group of patients. Men who have held but one job before entering the service are less likely to become military delinquents than men who have badly disorganized work histories.

American Review of Tuberculosis, New York

52:269-354 (Oct.) 1945

*Streptomycin in Experimental Tuberculosis. W. H. Feldman, H. C. Hinshaw and F. C. Mann.—p. 269.
*Streptothricin in Experimental Tuberculosis. W. H. Feldman and H. C. Hinshaw.—p. 299.
Chemotherapy of Sulfones and Sulfonamides in Experimental Tuberculosis. M. I. Smith and W. T. McClosky.—p. 304.
Anatomic Studies on Human Tuberculosis: XIX. Protracted Primary Tuberculosis in the Adult, with Some Observations on "Lymphoglandular-Endogenous Reinfection (Ghon)." K. Terplan.—p. 312.
Eosinophilia in Silicosis. W. J. Habeeb.—p. 337.
Tuberculosis of Tongue. L. L. Titche.—p. 342.
Founders of National Tuberculosis Association. R. G. Paterson.—p. 345.

Streptomycin in Experimental Tuberculosis.—Feldman and his co-workers report three experiments on guinea pigs, the first two being of short duration, the third extending over a 215 day period. In the latter, guinea pigs were inoculated with Mycobacterium tuberculosis forty-eight days before treatment with streptomycin was started. The animals received 6,000 units of streptomycin daily divided into four equal doses. The treated group consisted of 25 guinea pigs, while the group of untreated controls totaled 24 animals. When the experiment was terminated after 166 days of treatment, 17 of the untreated animals had died, compared to 2 of the group that had received streptomycin. Nearly all of the untreated controls showed at necropsy severe, widely disseminated tuberculosis while the tuberculous disease among the animals that had been treated was minimal. Thirteen of the treated animals had no tuberculosis grossly or microscopically. Nine of the treated animals living when the experiment was terminated gave a negative reaction to tuberculin. The authors conclude that streptomycin was effective in resolving or suppressing established experimental tuberculous infection in guinea pigs. The streptomycin preparations used had a low toxicity for guinea pigs in doses of 6,000 units per day and were tolerated without recognizable deleterious effects for a prolonged period. Although capable of combating or preventing anatomic changes due to Mycobacterium tuberculosis, streptomycin in most instances exerted a suppressive rather than a sterilizing effect on the infective agent. In some instances successful treatment with streptomycin resulted in the reversal of a positive sensitivity to tuberculin. Larger doses and more frequent administration of streptomycin might have enhanced the bacteriostatic effects. The striking effects of streptomycin in reversing a potentially lethal tuberculosis in the highly susceptible guinea pig and the low toxicity and corresponding safety of purified streptomycin are prerequisites of a drug worthy of clinical trial.

Streptothricin in Experimental Tuberculosis.—Feldman and Hinshaw tested streptothricin in experimental tuberculosis in guinea pigs. The streptothricin available and in the dose used was poorly tolerated by large, previously vigorous guinea pigs. Seven of the 10 guinea pigs treated with streptothricin died during sixty-one days of observation. Unlike streptomycin, which has a high therapeutic potential in tuberculosis of guinea pigs, streptothricin proved devoid of deterrent qualities that would suggest antituberculosis effects.

Recurrent Meningoencephalitis Due to Virus of Lymphogranuloma Venereum. D. W. Scott Jr.—p. 174.

Etiology and Pathogenesis of Rheumatic Fever.—Patients discovered to have a hemolytic streptococcus infection in army camps were transferred to special wards and were studied by means of a variety of laboratory procedures. Cultures were made repeatedly from the nose and throat, and the isolated hemolytic streptococci were classified serologically by the precipitin technics of Lancefield. Serial white blood cell counts, erythrocyte sedimentation rates (Westergren) and electrocardiograms were obtained. Each patient was studied for not less than three weeks and frequently for a longer period. During the period of intensive study, from Jan. 1 to April 15, 1944, approximately 1,500 patients were observed. As the basis for further investigation, Rantz and his associates point out (1) that rheumatic fever is invariably induced by infection with group A hemolytic streptococci, (2) that this syndrome is but a part of the whole complex involved in the poststreptococcic state, (3) that these clinical manifestations are the result of altered sensitivity of the tissues to products of the hemolytic streptococcus and (4) that repeated infection with different types of hemolytic streptococci may be necessary for the development of these disorders. If this working hypothesis is acceptable, it would appear (1) that sensitivity of the tissues must occur to some fraction or product of the hemolytic streptococcus and (2) that this fraction or product must be common to all types of group A streptococci It would seem desirable to obtain these substances in highly purified form and to determine whether they have induced the formation of circulating antibodies and whether the tissues of rheumatic persons are sensitive to them. Such an investigation might lead to technics which would permit the determination of dangerous streptococcus hypersensitivity and to possible preventive or therapeutic measures.

Putrid Pulmonary Abscess Without Foul Sputum.—Stats and Neuhof report instances of acute putrid pulmonary abscess without foul sputum. They have termed this variety "shut-off abscess" on the assumption that the bronchus communicating with the abscess is occluded as a result of an inflammatory reaction and cannot drain the contents of the abscess. The shut-off pulmonary abscess has a tendency to invade the pleura. The presence of such an abscess should be considered when (1) a cause for a putrid pulmonary abscess exists (or, in the absence of a cause, dental hygiene is poor), (2) thoracic pain is severe, prolonged or recurrent, (3) cough and expectoration are minimal or absent and (4) x-ray examination reveals persistent pulmonary infiltration with or without pleural effusion There are grave dangers inherent in a too long delayed diagnosis. If the possibility of this lesion is borne in mind, a correct diagnosis can be made. The excellent results achieved by adequate operations on the pulmonary abscess and on the complicating empyema that is often present provide an additional incentive to establishing the diagnosis of shut-off putrid pulmonary abscess

Visual Retention Test for Clinical Use A. L Benton —p 212

Arteriovenous Aneurysm of Great Cerebral Vein and of Circle of Willis.—The patient observed by Alpers and Forster was a youth aged 18 who was hospitalized because of headaches from which he had suffered since the age of 6 They were frontal, occurred once or twice a week and became more severe two months before entrance into the hospital In the last month the headaches were accompanied by dizziness, characterized by movement of objects in the environment The patient was somewhat euphoric, highly distractible and rather flippant. His reactions were slow; the intelligence quotient was 64 by the Stanford-Binet test. Because of the history of persistent headache and the evidence of calcification in the roentgenogram, a diagnosis of brain tumor was made. Ventriculographic examination revealed greatly dilated ventricles. The right lateral ventricle was opened At the glomus of the choroid plexus a large, tortuous mass of arteries and veins was found which ran toward the base of the skull and connected with the large vessels, supplying an aneurysm about the size of a hen's egg It was apparently an aneurysm of a branch of the circle of Willis, probably the posterior cerebral artery A part of its wall was calcified; there was a strong pulsation The patient died two days after the craniotomy. Necropsy showed the venous side of the aneurysm to be formed by the great cerebral vein, while the arterial supply was the posterior cerebral and choroidal arteries. As in previously reported cases, internal hydrocephalus was the only significant clinical feature.

Effect in Hemophilia of Globulins Rich in Fibrinogen.—Minot and his associates demonstrated that normal human plasma essentially free from formed elements, fibrinogen and prothrombin can cause a great reduction in the coagulation time of the blood in hemophilia when administered intravenously or intramuscularly. Such activity was associated with the plasma euglobulin of normal plasma and was deficient in hemophilic blood. Administration, intravenously or intramuscularly, of small amounts of the globulin fraction (fraction I) of pooled normal human plasma reduced the blood coagulation time of hemophilic blood toward or to normal values in 15 out of 16 instances in which it was employed. One of these patients responded to as little as 11.5 mg. of the globulin. In 1 patient the effect of the intramuscular administration of 125 mg. of the protein was minimal. The dosage for therapeutic use has not been established, but 200 to 600 mg. of the globulin has an effect equal to that obtained by 80 cc. of fresh plasma or 100 cc. of whole blood.

Prognosis of Renal Tuberculosis.—Nesbit and his associates present data on 260 cases of genitourinary tuberculosis observed for five years or longer. Males predominated over females in a ratio of 2:1. The urine in about one third of the patients was secondarily infected by organisms other than the tubercle bacillus. About half of the nephrectomized patients are living (an average of eleven years after operation) while 81.3 per cent of patients not operated on died (in an average of three years). They were unable to demonstrate that genital complications in the male increased the mortality of renal tuberculosis. The higher death rate among males is probably due to the higher mortality of tuberculosis generally in this group. The following three facts were found to be statistically significant: 1. In nephrectomized patients a lower rate of survival will be present in the group having acid fast bacilli demonstrated by guinea pig inoculation in the urine from the unoperated kidney than in those with normal urine on the unoperated side. 2. The survival of women is greater than that of men in urinary tuberculosis. 3. The mortality rate of genitourinary tuberculosis is adversely influenced by the presence of bone and joint or pulmonary lesions.

Cystoscopic Treatment of Stones in Ureter.—Dourmashkin has employed metallic dilators (tunneled bougies) for treatment of stones in the lower end of the ureter, and rubber bag dilators for calculi in the upper two thirds of the ureter. In a series of 1,550 cases of stones situated at all levels of the ureter and renal pelvis, cystoscopic manipulation of 1,253 resulted in 1,171 cases (93.5 per cent) in the expulsion of the stone without an instance of ruptured ureter or mortality resulting from instrumentation. The cases were divided into two groups: 689 with small stones less than 5 mm. in width and 564 with large stones, 5 mm. and more in width. In the small stone group the stones were passed in 99.7 per cent of the cases and in the large stone group in 85.9 per cent. Ample room for the downward passage of the stone was achieved by dilating the lower end of the ureter with metallic bougies and by using rubber bags at the higher levels. Passage of an ordinary catheter was sufficient to induce the expulsion of a small stone in the majority of cases. There are a number of mechanical factors which maintain renal drainage in ureteral stone cases. For this reason renal stones can be present for considerable lengths of time without appreciable renal injury. The majority of patients were treated in ambulatory fashion. Indwelling multiple catheters do not provide adequate dilatation in large stone cases and are apt to produce renal infection. In Dourmashkin's opinion forcible extraction of stones is contraindicated, as the same results may be obtained by more conservative methods without the danger of injury to the ureter.

Chyluria.—Yamauchi believes that physicians in the United States will encounter cases of chyluria among men and women returning from Filaria infested regions. The 45 patients presented by the author were all residents of Hawaii (where filariasis is not endemic) who had been exposed previously to filariasis. Clinical, laboratory and pyelographic studies based on the analysis of the records of these 45 cases of chyluria are compared and correlated with those recorded in the literature. The long period elapsing between exposure to Filaria and the onset of chyluria, the absence of eosinophilia and several other factors indicate that filariasis probably predisposes to this condition but does not actually initiate it. Urinary stasis has been considered to be the exciting cause of chyluria. Fornix rupture caused by urinary stasis results in a lymphaticourinary communication, and chyle appears in the voided urine. Minimal pathologic changes sufficient to form varices are probably present in the lymphatics without definite obstruction to the large retroperitoneal lymphatic vessels and thoracic duct. The presence of fat granules in a colloidal state, the presence of albumin, erythrocytes and lymphocytes, the pyelographic injection of the renal and perirenal lymphatics frequently associated with fornix rupture and pyelovenous reflux and the control of the condition by repeated intrapelvic lavages with sclerosing solutions indicate a lymphaticourinary fistula at the fornix of the calices. The control of chyluria can be accomplished by repeated intrapelvic lavages of silver nitrate solutions through inlying catheters. Urinary stasis must be removed. Fat must be restricted in the diet after such lavages.

Osteoid Osteoma.—Hamilton presents 5 cases of osteoid osteoma which demonstrate that the disease may be readily and correctly diagnosed. It is frequently confused with sclerosing nonsuppurative osteomyelitis of Garré, Brodie's bone abscess and osteogenic sarcoma. The diagnosis can be made, provided the pathologic process has developed to the point where there is roentgenographic evidence to support the clinical findings and the physician is aware of the possibility of an osteoid osteoma and knows the symptomatology, physical findings and x-ray evidence produced by the pathologic process. Localized pain of a dull, aching character, most annoying at night, with tenderness over the site of the lesion usually confined to an area from 1 to 2 cm. in diameter, is most characteristic. The majority of the patients are in the second or third decade of life. A typical roentgenogram of an osteoid osteoma reveals an oval to round area from a few millimeters to 1 or 2 centimeters in diameter, the center of which presents small areas of rarefaction and condensation. Surrounding this is a narrow zone of condensation, and just outside of this is a zone of rarefaction. The surrounding parent bone is, as a rule, sclerosed for a variable depth. Occasionally the first picture may be negative. This type of case should be restudied by x-rays at a later date, thus giving time for the lesion to develop. The prognosis is uniformly good provided all of the lesion is excised. On the contrary, if it is not removed completely, pain will continue or recur.

Bivalent and Pentavalent Gas Gangrene Antitoxins.—Hall believes that gas gangrene serum is not needed for wounds which receive prompt adequate surgery. The principal value of gas gangrene serum is prophylactic to prevent or delay anaerobic infection until adequate surgery can be secured, but it cannot take the place of adequate surgery. It has therapeutic value when used in adequate dosage as an adjunct to surgery in the treatment of malignant edema and gaseous gangrene due to anaerobic bacilli. Hall studied seven brands of gas gangrene antitoxin. Six of these were bivalent and were labeled to contain 10,000 units each of Bacillus perfringens and Bacillus septicus antitoxins. One was pentavalent and labeled to contain in addition 3,000 units of Bacillus histolyticus antitoxin and 1,500 units each of Bacillus novyi and Bacillus sordelli antitoxins. All of these antitoxins were first tested against a weak toxin of B. perfringens, which generally killed guinea pigs in a dose of 1 cc. but still produced lesions in a dose of 0.05 cc. Five of the seven brands of serum gave complete prophylactic protection against 1 cc. of this toxin in doses of 0.01 cc. or larger; all 5 failed in a dose of 0.001 cc. One gave complete protection in a dose of 0.1 cc. but failed at 0.01 cc., while another gave complete protection at 0.1 cc. and failed irregularly at 0.01 cc. The pentavalent serum was shown to have not only prophylactic but therapeutic action against infections in guinea pigs with a virulent culture of B. perfringens. The immunity conferred by 1 cc. of five antitoxins injected along with 1 cc. of B. perfringens was shown to persist for at least a week when challenged with at least 10 lethal doses of B. septicus culture. The pentavalent serum was shown to have prophylactic values in a dose of 0.1 cc. and therapeutic values in a dose of 1 cc. at twenty-seven hours against at least 100 lethal doses of B. novyi. It had prophylactic values in a dose of 0.1 cc. against at least 10 lethal doses of Bacillus histolyticus. The author concludes that there is no reason to doubt the prophylactic value of seven American gas gangrene antitoxins against the anaerobic infections for which they were intended. One of these serums has been shown to have good therapeutic values against B. perfringens and B. novyi but only slight therapeutic value against B. septicus under the conditions of a possibly too severe test.

Late Symptoms of Immersion Foot.—A group of 65 patients were studied by Fausel and Hemphill fourteen months after the occurrence of immersion foot. Of these, 49 had complaints and 42 had abnormal physical findings associated with chronic peripheral vascular disease secondary to immersion foot. Secondary symptoms following immersion foot are common and more persistent than usually thought. The main complaints are rest pain, numbness of the legs or feet, subjective coldness of the legs or feet and increased perspiration of the extremities. Abnormal physical aspects, particularly plantar ischemia, development of superficial varicosities and decreased peripheral arterial pulsation of the dorsalis pedis artery, usually unilateral and corresponding to the primarily affected extremity, exist in a surprisingly high proportion of patients who have complaints. The authors think that these complaints are on the basis of fibrosis of the extremity secondary to the initial inflammatory reaction after immersion rather than to secondary angiospasm. The persistence of peripheral vascular disease secondary to immersion foot should be brought to the attention of surgeons dealing with immersion foot in view of the fact that these cases may be a source of future persistent disability.

*Simple Method of Testing Sensitivity of Wound Bacteria to Penicillin and Sulfathiazole by Use of Impregnated Blotting Paper Disks. D. C. Morley.—p. 379.

Simple Test for Sensitivity of Wound Bacteria.—Blotting paper disks impregnated with penicillin solutions have been used by various workers to detect bacterial sensitivity to penicillin. Usually the disks are laid wet on the surface of an inoculated agar plate or are impregnated while lying on the agar by dropping penicillin solution on them. Blotting paper disks impregnated with penicillin before drying appeal to Morley as more convenient to use because they dispense with the need of maintaining suitable dilutions of penicillin, which must be frequently renewed because of their instability. As the dried disks can be stored over a long period and are always ready for use, they are likely to be most valuable in small laboratories in which a test of sensitivity to penicillin is a comparatively rare event. A similar method has been tried to detect sensitivity to sulfonamides. Although the implications of a negative result have not been determined, this method reveals a certain number of strains which are sensitive to sulfathiazole. It is quick and convenient.

Through and Through Bullet Wounds of Mediastinum, with Recovery. T. St.M. Norris.—p. 464.

Hepatorenal Syndrome Treated with Choline Chloride.—A man aged 27, who in childhood had had a mild jaundice, was admitted to a field dressing station in a state of severe anxiety and exhaustion. He was given barbital for five days but was still depressed. During the next three days he was given phenobarbital and in the next two days more barbital and sodium amytal. He became unconscious and anuric. After four doses of picrotoxin at two hour intervals he returned to consciousness. He passed three stools which contained blood and mucus and vomited six times but passed no urine. Dysentery was considered possible because of severe abdominal pain. He was given sulfaguanidine by mouth and dextrose in isotonic solution of sodium chloride intravenously. No urine was passed, vomiting continued and the abdomen became jaundiced. There was continued hiccup and vomiting, and jaundice became deeper. Choline was given and later methionine and choline, which resulted in gradual improvement and recovery. Barclay and Cooke state that the cause of failure of the liver and kidney function of this patient is obscure. The previous attack of jaundice probably rendered him more susceptible to hepatitis. Jaundice and hepatic degeneration have been described in barbiturate poisoning and some of these patients have had renal damage. Although liver damage of the degree seen in this patient is rare in barbiturate poisoning, this seems to be the most likely explanation.

Penicillin in Skin Conditions.—In the early days of penicillin treatment the drug was restricted to infectious conditions of the skin such as impetigo, ecthyma, folliculitis and sycosis. Later, when more penicillin was available, it was used to treat the infective element in septic eczema, seborrheic dermatitis and sulfonamide dermatitis and was used parenterally for boils and carbuncles. Penicillin spray has been used mostly. The patients were usually sprayed three times a day with ordinary throat spray. A solution of 200 to 500 units per cubic centimeter was used. With a strength of less than 200 units per cubic centimeter the failure rate increased, but no advantage seemed to be gained by increasing the strength above 500 units per cubic centimeter. The use of too strong a solution may even lead to sensitization or at least irritation. Penicillin emulsion made up with 30 per cent Lanette wax in water and containing 200 to 500 units per gram was effective in the same types of conditions as the spray but was particularly useful in infected weeping areas which need a dressing. Hellier and Hodgson have used penicillin emulsion successfully in outpatient clinics, and it will probably be the method of choice in civil practice. Parenteral administration of penicillin has been used in the treatment of carbuncles, severe or recurrent boils and streptococcic infections around the ear.

Anaphylactic Shock Following Intravenous Antigangrene Serum.—Borisenko-Mitlash and Popov state that infusions of large amounts of antigangrene serum are *not* infrequently complicated by anaphylactic reactions despite all precautionary measures. They have observed in a number of cases typical anaphylactic shock terminating in death. They have seen instances of early shock following the introduction of the first few drops of the serum, as well as instances in which shock occurred one to four hours after the infusion. These late fatalities due to anaphylactic shock were erroneously considered by many as deaths due to toxemia of gas gangrene. Besredka's law is not infallible as far as prophylaxis of serum infusion is concerned. His method of desensitization, which consists in injection of a small amount of serum intramuscularly one and one-half to two hours previous to the infusion, is quite reliable in intramuscular, intraperitoneal and subdural injections of serum. It is less reliable in intravenous infusion of large doses of heterogenous serum. Substitution of the intramuscular method of administration of serum for the intravenous lowered the mortality by from 7 to 10 per cent. Prophylaxis of anaphylactic shock in intravenous infusions of large doses of antigangrene serum can be more successfully accomplished by the simultaneous employment of two methods, the desensitization according to Besredka and narcosis with 0.25 per cent solution of evipal in 400 cc. of isotonic solution of sodium chloride with 1 cc. of ephedrine. The infusion must be performed slowly. The nature of the reactions following intravenous infusions of antigangrene serum requires further elucidation.

Book Notices

What People Are: A Study of Normal Young Men. By Clark W. Heath, in collaboration with Lucien Brouha, Lewise W. Gregory, Carl C. Seltzer, Frederic L. Wells and William L. Woods. The Grant Study, Department of Hygiene, Harvard University. Cloth. Price, $2. Pp. 141, with 8 illustrations. Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1945.

This book is to be regarded as a brief introduction to the point of view of the Harvard Grant Study and the methods used to study superior normal young men from 17 to 24 years of age at Harvard University in order to discover the physical, mental and social traits and characteristics related to relative success or failure some fifteen to twenty years hence. It is a study of normal behavior rather than of disease or abnormality.

The principle on which the study was founded is that the segment of the population which was successfully carrying on the work of the world had lacked the attention it merited by investigative technic even now available. It points out that the concept of "normal" is too often the idea of absence of abnormality.

The study is distinguished by the scope of the appraisal methods in which experts from various fields have appraised their normal personality traits, adjustment to environment, socioeconomic status, mental ability, morphology, physiology and pathology. A large number of measurements or ratings were made under each of these leads. The data cover 238 carefully selected cases appraised during the first four years of study, 1938 to 1941 inclusive. The appendixes give the range, mean and standard deviation of these measurements; also the frequency and percentage for characteristics which were rated but not measured. No statistical results are included to show the quantitative relationships between the traits, abilities, characteristics and performances measured. The approach in the main has been clinical, with each specialist relatively free to appraise the subjects in the manner best suited for his own field.

The aim is to continue the study indefinitely as an institution rather than operate a project limited in time and scope. The intention is to continue the validation of various tests by long-time follow-up and to develop new procedures as they may be found necessary. The continued objective will be to discover the elements making for integration, drive and economic success in life and to verify the hypothesis that leaders of people usually rise from the energetic, well and fit types with higher quality for health than from the opposite. So far there are no conclusions along this line, and there cannot be until the careers of the men are followed.

The selection of subjects was limited to those men who were among the best conformers to social and scholastic disciplines as approved by the deans of their respective colleges. This limits the study tremendously, as there appears to be no control group of less able students. The preconception is that the leaders will arise from the sample selected. A fundamental limitation is that the basic measurements are almost devoid of measurements now made in physical education: motor skill, strength, posture, balance, flexibility, agility, power and some specific aspects of muscular and cardiovascular endurance which are better than the tests used. Analysis of weight by bone, muscle and fat quotas, using appropriate prediction equations for each, composite dynamometer strength per pound of weight, heartogram, electrocardiogram, vital capacity for surface area, expiratory force and breath holding after standardized exertion are other possible tests. The appraisal of the motor qualities seems inadequate to experts in physical education. If health is related to health habits, athletic participation, recreation and measurable aspects of fitness, there should be more careful appraisal of these traits and qualities because of the fundamental hypothesis set up to be verified or rejected. Amount and type of exercise and a complete athletic record seem important enough to record in some detail.

The investigation of mental characteristics impresses one as having been carried out with considerable regard for precision and reliability. In the field of abilities and achievements the research leaves little for criticism or suggestion except that, if special abilities are to be measured at all, the use of Thurstone's measure of primary mental abilities would have been more defensible than the ad hoc special ability measures employed.

In the field of personality description, however, it is unfortunate that no attempt has been made to measure with respect to the half dozen or more clearly defined personality factors revealed as basic for the factor analytic research of the past fifteen years. Even if these assessments had to be made by behavior ratings, by questionnaires or by dynamic projection tests of the thematic apperception type it would have been better—for any attempt at future alinement of findings with general psychologic knowledge—than to depend on a rather ill assorted set of trait ratings or the broken reed of the Rorschach test.

Diagnostic Procedures and Reagents: Technics for the Laboratory Diagnosis and Control of the Communicable Diseases. Second edition. Fabrikoid. Price, $4. Pp. 549, with illustrations. New York: American Public Health Association, 1945.

This is a complete revision of the first edition with the addition of nine new chapters. There are no numbers given to the chapters, but twenty-eight subjects are discussed by nearly that number of different authors, although some authors have been responsible for more than one chapter. The chairman of the Standard Methods Committee, William D. Stovall, had the task of collecting the manuscripts. He, with Lois Almon, also prepared the chapter on pathogenic fungi. As is to be expected, there is no uniformity in the style of writing or in the arrangement of the subject matter. However, each author has conscientiously reviewed the literature, and the long lists of references are valuable guides to further study of any of the technical procedures briefly described. While the title page indicates that the technics for the laboratory diagnosis and control of communicable diseases make up the subject matter, the different authors, depending on their experience, consider the topics differently. One author may stress technic for the identification of organisms, formulas and new methods as well as old, while another considers interpretation of laboratory findings as applied to clinical diagnosis. Control measures, such as quarantine regulations in diphtheria, meningococcic infections, pertussis and streptococcic infections, are discussed. Procedures for prophylaxis and immunization are not given, probably because they are not of diagnostic significance. However, the inclusion of such information would have been helpful to health officers, clinical pathologists and other physicians who are called on to keep the medical profession and the public informed on timely methods of preventive medicine. While this book can in no sense be considered a textbook of laboratory methods, it is a useful guide to the literature on the laboratory diagnosis of communicable diseases.

Dental Chronology: A Record of the More Important Historic Events in the Evolution of Dentistry. By Hermann Prinz, A.M., D.D.S., M.D. Cloth. Price, $3. Pp. 189, with 97 illustrations. Philadelphia: Lea & Febiger, 1945.

This is a small book containing the dates of what the author regards as important events in the evolution of dentistry. It also lists the names of persons who are thought to have made notable contributions to its development. The contents are divided into three periods: (1) antiquity, to the year 1000, the middle ages, from 1000 to 1728, and modern times, since 1728. For the most part the events selected are listed by dates with little or no comment as to their significance. One is led to wonder why certain events and certain persons are listed and why others are omitted, for there seems to be some glaring omissions even allowing for the fact that in any compilation such as this there could always be differences of opinion as to what should or should not be included. For example, no mention whatever is made of men or events connected with either the first or the second world war, which is astonishing, for in both wars remarkable advances were made which profoundly influenced the evolution of dental practice and dental teaching. The contributions of certain dentists in both wars were of such distinction as to deserve a place in any dental chronology. The author does state that "the book does not make a pretense of serving as a substitute for a competent history." For those interested in the date of occurrence of particular events in dental history this book might prove to be useful for reference.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

VIRAL INFLUENZA

To the Editor:—For several months I have been seeing an upper respiratory infection which is different from any previously seen. It vaguely resembles atypical virus pneumonia but simply does not progress into the lungs. It differs from an ordinary common cold in a number of respects, although it is quite similar. A few observations of characteristics which distinguish this ailment are its great contagiousness, the apparent susceptibility of all small children, the mildness in infancy and greater severity in later childhood, the extreme nervous irritability which attends it, the absence of coryza at first followed by an irritating mucoid nasal discharge later, a tendency to epistaxis, the almost universal hemorrhagic appearance of the tympanic membrane and the frequent bleb formation on the drum with severe pain, the comparatively mild pharyngitis, the intractable late cough, the recurrence or perhaps reinfection due to immunity of short duration, secondary anemia out of proportion to the expected effect of the illness, susceptibility of the air passages to changes of temperature for long periods and, last, the few serious complications and sequelae and the low mortality up to this point. The disease is increasing in severity rapidly. I have observed an increase in the number of cases in which abdominal pain, vomiting and diarrhea occur about the fourth or fifth day after onset. My facilities for bacteriology are limited to the identification of what might be termed the "major organisms." Throat and nose cultures show only a gram-positive diplococcus either in pure culture or with short chain streptococci. I am sure that this is not due to either of these organisms. The gram-negative bacillus associated with influenza has been lacking. I did not see the influenza epidemic of 1917 and 1918, but from the descriptions heard and read I should say that the infection described more closely resembles it than does the infection of the upper respiratory tract which has been loosely called "flu" during my medical life. Somewhere adequate bacteriologic studies have undoubtedly been done. Will you give me an opinion and the probable diagnosis? In favor of the diagnosis of influenza is the fact that 2 patients who followed a fairly typical course developed unquestioned influenzal meningitis, I now in the process of recovery with anti-hemophilus type B serum therapy. I am entirely convinced that good results are not forthcoming from sulfonamides or penicillin.

J. M. Albergotti Jr., M.D., Orangeburg, S. C.

Answer.—The first statement in the query has a familiar ring in the ears of an epidemiologist. When periodic epidemic waves of a contagious disease appear after long intervals, the disease is apt to be regarded as a new one and "different from any previously seen." The experience described in the query was the same in Philadelphia and elsewhere in December and January. Evidence of infection with the B virus of influenza was discovered in many patients locally and elsewhere in the country. Influenza B virus was probably the cause of the epidemic, as the inquirer suspects, because of its contagiousness, prevalence in childhood, mild pharyngitis, irritability, myringitis, cough, few complications and the recurrences as described. Among adults the symptoms were similar. In adults the pharynx was often intensely red and edematous but gave little discomfort; headache, general aching, sweating, paroxysmal coughing and irritability or depression were prominent, as were recurrences after several days or even two weeks.

In addition to the clinical picture described, there were numerous cases of viroid or of viral pneumonia (typical atypical [sic] pneumonia). But whether these were caused by the B virus of influenza or other ones was not determined. As noted in the query, there were also instances of viral dysentery, commonly called nausea, vomiting and diarrhea both with and without evidence of involvement of the upper respiratory tract, like those which occurred in epidemic form in Philadelphia in 1943 and 1944 (Reimann, H. A.; Hodges, J. H., and Price, Alison H.: Epidemic Diarrhea, Nausea and Vomiting of Unknown Cause, The Journal, Jan. 6, 1945, p. 1).

The discussion illustrates the present confusion in diagnosing different but similar clinical entities which cannot be further clarified until methods for the demonstration of the respective etiologic agents are available. Epidemics of influenza with or without pneumonia, of viroid with or without pneumonia, of viral dysentery and of the ill defined group of the common colds are seasonal and may overlap. At present some of them can be diagnosed tentatively only by the predominance of characteristic symptoms, signs and laboratory evidence of the respective diseases. For influenza the Hirst red cell agglutination test, the complement fixation test and the isolation of the virus establishes diagnosis. For viroid the cold agglutination test is of value after the disease is over and perhaps the newly discovered virus of Eaton may eventually be isolated. For common colds and for viral dysentery the diagnosis depends on clinical and epidemiologic evidence alone, as described in the paper referred to. Ordinary bacteriologic cultures of the nose and throat are of no value in diagnosis.

The inquirer is in error when he states that the recognition of meningitis caused by Hemophilus influenzae (Pfeiffer's bacillus) supports a diagnosis of influenza. Pfeiffer's bacillus, the so-called influenza bacillus, has nothing to do with influenza as we now understand it to be caused by influenza viruses A and B and probably X or Y. The habit of loosely calling all minor febrile diseases "flu" should be stopped. Influenza is now an established etiologic entity and must be regarded as such for the sake of accuracy and in view of current use of specific prophylactic vaccine.

It is true that neither the sulfonamide compounds nor penicillin have any specific influence in viral infections of the kind in question.

It may be pointed out incidentally that streptomycin seems to be of value for meningitis caused by H. influenzae.

THE GAY TREATMENT FOR ASTHMA

To the Editor:—I have heard recently of some special treatment for asthma that is given by Dr. Fred S. Gay of Biloxi, Miss. Can you tell me the nature of this treatment?

M.D., Wisconsin.

Answer.—According to Dr. Gay, he accepts patients only by appointment and only a limited number at any time. He requests his patients to stay under his immediate observation for a week, after which they go home and continue treatment as he directs them. Dr. Gay says also that he is always glad to furnish the patients' family doctor with copies of the prescriptions he gives the patients. Dr. Gay states that he "never did advertise in any way and that the only way any one ever heard of him was from some patient he had treated."

Reports indicate that his methods have developed a considerable amount of interest among the medical profession and that some physicians have been visiting him to secure the details of his technic, and for that reason this subject is published in Queries and Minor Notes in The Journal.

In response to an inquiry Dr. Gay has written that he does not use any specific new method of treatment of asthma. He endeavors to correct any abnormality that may exist, paying particular attention to the gallbladder and kidneys.

Patients are carefully examined and given the medication which according to Dr. Gay's judgment is indicated in each individual case. Most patients are given some form of calcium, such as calcium lactate or some form of liquid calcium, such as Calmulsion, in varying quantities and a prescription containing Fowler's solution and potassium iodide in varying quantities figured according to age, weight and general condition of patient. To this is added where and if indicated small quantities of tincture digitalis or phenobarbital put up in a vehicle of plain water, sometimes sweetened and sometimes colored red with an inert coloring substance of no medical value. In addition he oftentimes gives an oil solution of amphetamine solution, 2 drachms to 2 ounces of light petrolatum for nose drops and insists that the intestinal secretions be kept acting well at all times, for which he recommends a tablet containing pure bile salts and cascara, such as Colopo Tablets, made by the G. W. Carnrick Company, or bile salts with cascarin, made by Parke Davis and Company.

Dr. Gay supplies the medicine to his patients in most cases and requests that they report their general condition, weight and other details to him by mail at regular intervals and directs them as to procedure over a period of two years or more and claims that more than 90 per cent of his patients report improvement and in a large percentage complete relief from asthma within a two year period. He uses no ephedrine nor opiates but allows all patients to take any temporary relief medicines at any time if needed, including epinephrine, aminophylline ,and ephedrine.

SIX YEAR OLD BOY SHOULD SLEEP ALONE

To the Editor:—Is it harmful from a physical or mental standpoint for a boy aged 6 years to sleep with his father?

M.D., New York.

Answer.—In general it is more healthful for a child to sleep alone, certainly from the point of view of emotional health. Although serious harm would probably not result from a 6 year old son sleeping with his father, it is poor mental hygiene in that the child is being placed in a situation which may provoke anxiety. The quite normal feelings of love, envy, jealousy and fear that any son may have toward his father may all be aggravated by such an arrangement. It is better for a child to sleep alone if the physical condition of the home will permit.

HEAT CRAMPS OCCURRING ONLY AT NIGHT

To the Editor:—A man aged 27 has had eight seizures in six years, usually coming at night and awakening him with nausea. Vomiting nearly always follows and occasionally diarrhea. Then in about thirty minutes he notes a stiffening of his fingers and slowly they go into extensor tetany. The legs and feet next go into extensor spasm. Then the abdominal muscles tighten and finally the facial muscles draw stiffly. The thorax has never been involved. When the attack is allowed to progress to its fullest extent it is extremely painful. There are never any headache, clonic convulsions, incontinence, cry, loss of consciousness, numbness, paresthesias or resultant paralysis. The first attack was in 1938 during hot weather, and salt was given orally and seemed to control the seizure. Since then the patient has asked for salt and is given intravenous solution, since oral salt makes him ill, and always obtains relief. It is not quite clear whether or not all attacks have been preceded by perspiration. Attempts to relieve attacks by calcium were useless. There has not yet been an opportunity to observe an attack, but plans are being made to obtain samples of blood for testing of the potassium, sodium, calcium and carbon dioxide combining power.

D. I. Thompson, Captain, M. C., A. U. S.

Answer.—The symptoms are consistent with a diagnosis of heat cramps, a malady associated with loss of salt in the sweat, painful cramps in the voluntary muscle of the extremities and relief following replacement of sodium chloride. The age, sex, periodicity and environment likewise conform. Nausea and vomiting are unusual precursors but, if they occur, tend to aggravate the pathologic processes due to increased loss of electrolytes from the body. The pain in the muscles is the incapacitating feature of heat cramps. One should inquire whether the patient had been engaged in strenuous activity on the day prior to the onset of symptoms. Under such circumstances loss of sodium chloride in the sweat may have depleted the body content to a critical level. The muscle spasms are not usually referred to as tetany, and the flexors are more often affected than the extensors. As noted in the query, it would be desirable to determine the concentration of serum electrolytes, particularly serum sodium, calcium and carbonate. Idiopathic nocturnal cramps cannot be excluded from the evidence presented. A review of the literature on heat cramps by J. H. Talbott appeared in *Medicine* (**14**:323 [Sept.] 1935).

INCOMPATIBILITY OF CODEINE AND AMMONIUM CHLORIDE

To the Editor:—This inquiry concerns the use of codeine in sedative cough mixtures. It is generally stated in the pharmacology of codeine that it is incompatible with ammonium chloride and alkalis (the Merck Index, ed. 5, Rahway, N. J., Merck & Co., Inc., 1940, p. 159). Yet in Beckman's book (Beckman, Harry: Treatment in General Practice, ed. 4, Philadelphia, W. B. Saunders Company, 1942, p. 21) codeine and ammonium chloride are combined in a cough mixture. Then too, Goodman and Gilman (Goodman, Louis, and Gilman, Alfred: The Pharmacological Basis of Therapeutics, New York, Macmillan Company, 1941, p. 220) suggest that codeine may be profitably combined with the sedative expectorants without excluding ammonium chloride or the citrates.

Israel Pine, M.D., Belle Harbor, L. I., N. Y.

Answer.—Although ammonium chloride is stated to be incompatible with codeine preparations because of the liberation of ammonia, which would precipitate the alkaloid as a base, such mixtures as that cited by Beckman may be prepared by mixing solutions of the drugs, rather than the dry forms, and then adding the solvent. The permanence of such preparations is usually adequate for clinical use.

SULFONAMIDES

To the Editor:—When were the sulfonamides first available for general use by physicians?

Martha O'Malley, M.D., Boston.

Answer.—The sulfonamides apparently were first available for general use by physicians in Germany in 1936 and in Great Britain, France and the United States in 1937. It is understood that sulfanilamide could be purchased in Boston as early as the middle of November 1936. However, it was a proprietary brand and at that time apparently was not widely distributed.

INTRAVENOUS INJECTIONS

To the Editor:—Is there any more danger in using the saphenous vein at the ankle for intravenous fluids than there is in using the vein of the hand and arm?

J. Vernon Pace, M.D., Paducah, Ky.

Answer.—In the absence of local contraindication such as varicosities, old thrombophlebitis, phlebothrombosis and the like, and with the body in a horizontal position, fluids may be introduced into any accessible vein without significant difference in risk.

MALARIA

To the Editor:—What proportion of malaria patients are prone to have recurrences and what is the number of permanent cures? In other words, what can be expected as regards the veterans having recurrences and how long will it be necessary for them to continue treatment in order to effect a cure? What is the best accepted treatment of malaria today and the dosage?

Leslie C. Taylor, M.D., Lakewood, Ohio.

Answer.—An accurate answer to the first question is not possible because the figure is constantly changing. Of the many thousand cases of malaria acquired during the war, relatively few relapses are still occurring. During the war only two types of malaria, falciparum (malignant tertian) and vivax (benign tertian) were of importance. Falciparum malaria is the most severe type and responsible for practically all deaths (which were rare except in prison camps) but has a fortunate biologic characteristic in that after the acute attack it rarely relapses. Vivax malaria, on the other hand, is practically never fatal of itself but will relapse in from 35 to 50 per cent of all instances. With each relapse there is a decreased possibility that another will occur. There is as yet no drug which can be relied on to terminate an infection regardless of amount or duration. The rationale of therapy is to treat each relapse as it occurs and use supportive measures when indicated. Recommended treatment for uncomplicated malaria is atabrine dihydrochloride 0.2 Gm. (3 grains) every six hours for five doses; thereafter 0.1 Gm. (1½ grains) three times daily for five days. It should be taken with fluids, 200 or 300 cc. of water, or before meals in order to reduce gastric irritation.

PERSISTENT HERPES ZOSTER

To the Editor:—A patient has had herpes for three months involving the right lower quadrant of the abdomen. All the known recommended treatments have been tried, including vitamin B, ethyl chloride spray and collodion. I understand that high voltage x-ray therapy has not given satisfactory results. Is there any new treatment for this affliction?

W. J. Klinck, M.D., Lennoxville, Que.

Answer.—An additional treatment for herpes is 5 grains (0.32 Gm.) of quinine hydrochloride by mouth three times daily for four days. If no relief is obtained, administration of one ampule of double strength posterior pituitary injection hypodermically daily for two days in succession might be tried. Section of the right tenth, eleventh and twelfth posterior roots of the thoracic spinal cord and right first posterior root of the lumbar spinal cord may be resorted to if other measures fail. Before undertaking such an operation, spinal anesthesia should be administered in order to determine the upper level of the herpetic pain in the thoracic cord.

VALSALVA EXPERIMENT AND PAROXYSMAL TACHYCARDIA

To the Editor:—Will you please explain to me what the Valsalva experiment is, its importance and its use in auricular tachycardia.

William R. Sulman, M.D., Hazleton, Pa.

Answer.—The Valsalva experiment consists in an attempted forced expiration with the glottis (or mouth and nose) closed in contrast to the Müller experiment, which is an attempt to inspire forcefully with the glottis closed. The Valsalva experiment increases sharply the intrathoracic pressure and tends to prevent blood from entering the thorax and the heart, with resulting temporary decrease in heart size. There is a vagal reflex effect from this that may act to stop paroxysmal auricular tachycardia. Usually, however, such a therapeutic measure fails, although it is of interest to try it in cases of obstinate auricular paroxysmal tachycardia.

TIME OF DAY FOR METABOLISM TEST

To the Editor:—Basal metabolic tests are done during the morning hours on an empty stomach. Will you kindly advise the reasons, if any, that tests cannot be made during the afternoon?

J. W. Lane, M.D., West Chicago, Ill.

Answer.—Basal metabolism determinations are done under so-called basal conditions, namely after a rest period of at least one-half hour and twelve to fourteen hours after the last meal. The digestion of food raises the basal metabolism somewhat, particularly protein food, because of its specific dynamic action.

There is no good reason why under some circumstances basal metabolism tests should not be done in the afternoon if the program of the patient is arranged in such a way that he sleeps later in the morning. For most patients the afternoon would be an unsatisfactory time because work and the emotional stress and strain of ordinary daily events might raise the metabolism even though it was preceded by the usual rest period.

ARTIFICIAL RESPIRATION

JULIUS H. COMROE JR., M.D., and ROBERT D. DRIPPS, M.D.
Philadelphia

A recent review article[1] has pointed out the paucity of quantitative data on which valid comparisons may be made of various technics for performing artificial respiration. At present the two most widely discussed methods are the Schafer prone pressure and the Eve tilting[2] or gravity technics; the former is recommended by the American Red Cross, while the latter is used extensively by the British navy. In view of the prolonged and often bitter controversies in the field of artificial respiration, it is interesting to note that the relative effectiveness of these two methods has been measured in only 3 subjects who might possibly be considered to be in need of artificial respiration. Each of these 3 was anesthetized deeply with ether, then rendered apneic by passive hyperventilation and immediately subjected to the Schafer and Eve technics while measurements of tidal air were made.[3] Data on these patients are given in table 1. It indicates that much more data are needed to prove that the widely accepted Schafer method is superior or even adequate.

As far as we know, these two methods have never been compared quantitatively in typical cases of respiratory failure with asphyxia. In the cases in table 1 the blood oxygen tension was undoubtedly high and the carbon dioxide tension low as a result of the period of hyperventilation induced by the investigators. In cases encountered clinically in which artificial respiration is required, asphyxia always exists, i. e., arterial oxygen is very low and carbon dioxide is very high.[4] This report is concerned with 2 such patients with complete respiratory arrest in whom it was possible to compare various resuscitation technics. In patient C. M. respiration ceased following a severe head injury; in B. R. it stopped after intraventricular rupture of a brain abscess. Both patients were unconscious throughout. In both, arterial blood pressure was low (40 to 70 mm. of mercury) and despite plasma, saline or gelatin infusions it remained near shock level until death (in seven hours in C. M., in two and one-half hours in B. R.). Respiration was measured by applying tightly a full face mask equipped with flutter valves; the expired air was conducted through a Bohr meter and measured. In both, *an endotracheal tube was passed through the larynx to* ensure an open airway. Arterial blood gas analyses were performed by means of the technic of Van Slyke and Neill; blood p_H was measured in a closed glass electrode at 38 C.

RESULTS

1. *Comparison of Schafer and Eve Methods.*—The data obtained (table 3) show the complete inadequacy of the Schafer method in these 2 cases. The tidal air produced by the Schafer technic varied from 71.5 to 117 cc. (normal is 400 to 500 cc.) despite the fact that the motions used conformed closely to the approved technic.[5] Two different operators (both experienced) were used, each weighing approximately 180 pounds (81.6 Kg.). It is instructive to note that prone pressure applied to C. M. at a time when he was lying on a thin mattress produced only 75 cc. per cycle as compared with 117 cc. when the mattress was removed leaving only a hard plywood tilt table; too often artificial respiration is given to a mattress rather than to the patient.

On the other hand, the Eve tilting or gravity technic (with the patient tilted through an angle of 45 degrees in each direction) produced an adequate exchange of 286 to 500 cc. per cycle. No comparison of possible beneficial effects on circulation of the two methods was possible in this study.

It is apparent that the Schafer method failed almost completely to ventilate these patients. Widespread popular reliance on this technic rests chiefly on its ability to maintain a good respiratory exchange (360 to 1,000 cc. per cycle[6]) in subjects who have voluntarily suspended their respiration. It has long been known that nonrigid cadavers cannot be ventilated by the Schafer technic, values of *20 to 50 cc. per cycle* having been reported.[6] Proponents of the Schafer method have dismissed these observations on the grounds that loss of muscular tone, increased blood in the lungs and possible respiratory tract obstruction in such subjects make them unfit for test purposes. However, there is good reason to suspect that a patient who is unconscious, apneic, asphyctic and in shock because of profound medullary depression resembles a fresh cadaver more

closely than he resembles a normal healthy subject. Our evidence indicates that this resemblance certainly exists so far as respiratory exchange is concerned. The Schafer method depends to a large extent on the elastic recoil of the lungs and tonicity in the respiratory muscles; since these are absent in the deeply asphyxiated patient, Schafer's method becomes of least value when most needed. Conversely the Eve tilting method is efficient when tonus and elasticity of these structures are absent.

TABLE 1.—*Comparison of Schafer and Eve Methods by Previous Investigators*

	Tidal Air	
	Schafer	Eve
Waters and Bennett [3]	160 cc.	150 cc.
MacIntosh [3]	340 cc.	580 cc.
Eve [3]	530 cc.	850 cc.

Comment: There are two important considerations in any discussion of artificial respiration. The first is the time element. When artificial respiration is needed, it is essential that the most immediately available method be employed instantly. This usually happens to be the Schafer prone pressure method, for even simple mechanical devices such as a tilt board or bellows are rarely available in the first few minutes, even in large hospitals. The second important consideration is that, as soon as possible, the most efficient available method of artificial respiration should replace the emergency measure. We agree with all who have claimed that insistence on the sole use of mechanical "gadgets" often leads to loss of life because of the minutes in which no therapy at all is instituted. We do not agree, however, that reliance is to be placed on the Schafer method except as a very temporary emergency measure.

TABLE 2.—*Arterial Blood and Alveolar Gas Studies During Tracheal Insufflation of Oxygen*

			Arterial Blood				"Alveolar" Air	
	Time	Oxygen Therapy	Oxygen Saturation, %	pH	CO_2 Content, Vols. %	PCO_2, Mm. Hg	O_2, %	CO_2, %
Patient—C. M. Man aged 53	2:57 p. m.	Tracheal insufflation, 6 liters per minute for 7 minutes	95.8	6.86	64.8	166	....	....
Height, 6 feet Weight, 196 pounds	3:18 p. pm.	Tracheal insufflation, 10 liters per minute for 20 minutes	92	6.80	72.1	207	....	....
	6:30 p. m.	Tracheal insufflation, 6 liters per minute for 3 hours	75	6.67	85.8	314	52.3	29.7
	6:40 p. m.	Hyperventilation with anesthesia bag, 40 respirations per minute for 10 minutes	95	7.00	55.5	106	....	....
	7:00 p. m.	Tracheal insufflation, 6 liters per minute for 15 minutes	75	6.83	70.9	189	47.7	24.4
Patient—B. R. Woman aged 41	9:15 p. m.	Tracheal insufflation, 11 liters per minute for 30 minutes	90	6.86	55.9	142	....	....
Height, 5 feet 5 inches Weight, 135 pounds	9:48 p. m.	Tracheal insufflation, 11 liters per minute for 63 minutes	65	6.88	61.6	152	....	....

On the other hand, we do not wish to imply that the Eve method is the best available or best possible technic for artificial respiration; valuable minutes may be lost in improvising a tilt table, and the operation of such improvised tables usually requires the expenditure of considerably more energy and manpower than is required with other methods.

Furthermore, at the earliest possible moment the patient's care should pass from the hands of the fireman, policeman or passerby to those of a physician highly trained in resuscitation; in most hospitals this is the anesthesiologist. Resuscitation of the near dead is a complex matter involving specialized knowledge concerning many aspects of respiratory, circulatory and central nervous system physiology. It is of the utmost importance that clinicians and physiologists collect quantitative data on many more such apneic, asphyxiated patients in whom actual need exists for artificial ventilation.

2. *Intratracheal Insufflation with Oxygen.*—In 1909 Meltzer and Auer [7] noted that life could be maintained for hours in apneic animals without any external respiratory movements if a stream of oxygen was directed through a catheter toward the bifurcation of the trachea. This finding has been confirmed frequently.[8] However, it has been pointed out on several occasions [9] that the oxygen insufflation technic does not effectively eliminate carbon dioxide from the lungs; to accomplish this, actual expansion on and collapse of the lungs are required. Carbon dioxide has a greater molecular weight than oxygen and does not diffuse more rapidly in air than oxygen, despite the greater ease with which it diffuses through water and through living membranes. Nevertheless the original insufflation technic is not infrequently used (without additional rhythmic compression of the chest) because of its ease and simplicity.

In the course of the studies just described we were able to make observations on arterial and alveolar gas tensions during intratracheal insufflation of oxygen (table 2). In patients C. M. this technic resulted in an initial arterial oxygen saturation of 95.8 per cent and in B. R. of 90 per cent. However, at these times the

arterial carbon dioxide tensions were 166 and 142 mm. of mercury and the arterial p_H values were 6.86 and 6.86 respectively. In C. M. we attempted later to obtain alevolar air samples by compression of the chest and simultaneous aspiration of a sample of tracheal air through the previously flushed catheter. While such collections are obviously inaccurate in an apneic, unconscious patient, the figures obtained should be lower rather than higher than true values. The figures of 29.7 per cent of carbon dioxide and 24.4 per cent of carbon dioxide in such "alveolar air" together with an arterial blood carbon dioxide tension of 314 mm., of mercury (equivalent to 44 per cent of carbon dioxide in the alveolar air) leave no doubt regarding the tremendous accumulation of carbon dioxide that may occur during respiratory arrest, despite intratracheal insufflation with oxygen.[10]

Although these patients had a pink color and were obviously well oxygenated, it is apparent from the arterial blood analyses that the blood bathing the central nervous system was grossly abnormal in other respects. The enormous increase in carbon dioxide tension and acidity of the arterial blood are factors not so readily appreciated by the clinician as a decrease in arterial oxygen saturation. While all physicians are familiar with the stimulation of respiration and circulation that follows inhalation of low concentrations of carbon dioxide (5 to 7 per cent) in healthy men, it is not so universally known that high concentrations of carbon dioxide act as a narcotic.[11] The latter depress the medullary centers and the cerebral cortex and lead to decrease in respiration, vasodilatation and fall in blood pressure. The concentrations of carbon dioxide present in the blood of C. M. and B. R. must certainly have exerted a narcotic depressant effect. The extremely low p_H values (6.67 to 6.88) in these patients undoubtedly acted similarly. While a moderate degree of acidosis may increase respiration and circulation reflexly through the chemoreceptors, severe acidosis depresses all vital functions including circulation and respiration. The arterial p_H values in these patients are among the lowest ever recorded (similar figures having been reported only in terminal nephritis [12]). In patient C. M. the low p_H was due in large part to carbon dioxide retention, since hyperventilation with an anesthesia bag [13] for ten minutes at a rate of 40 cycles per minute reduced the arterial carbon dioxide tension to 106 mm. of mercury and increased the p_H to 7.00. Accumulation of lactic acid due to severe tissue anoxia and fixed acid retention due to intense renal vasoconstriction caused by the low blood pressure were probably responsible for some of the acidosis.

These studies emphasize that artificial respiration, to be maximally effective, must not only raise blood oxygen to normal levels but must reduce blood carbon dioxide to normal levels. The original oxygen insufflation technic provides adequate oxygen but permits accumulation of narcotic concentrations of carbon dioxide; consequently it should not be employed for more than a few minutes without additional rhythmic manual compression of the chest. Tingley's plea for a much faster rate in artificial respiration for asphyxiated patients [14] is probably justified; we do not believe that these unconscious patients require excessive amounts of oxygen, but it certainly is essential to reduce carbon dioxide to normal levels. There is no doubt that low levels of blood carbon dioxide may be harmful because of the resultant cerebral vasoconstriction;[15] however, it is unlikely that any existing method of manual artificial respiration could produce enough hyperventilation in fifteen minutes to do harm. Excessive hyperventilation may of course result from the improper use of mechanical resuscitators.

It is important to note that in both patients arterial oxygen saturation fell (from 95.8 per cent to 75 per cent and from 90 per cent to 65 per cent) with the prolonged use of the intratracheal insufflation technic. While this may have been due in part to the formation of pulmonary edema fluid, we feel that the development of atelectasis is a much more likely explanation. The coexistence of alveoli filled with oxygen (which is readily absorbed into the blood), apnea and inability to cough up secretions presents the ideal situation for plugging of bronchioles and subsequent atelectasis. Evidence in favor of this concept was provided by Comroe, Dripps, Dumke and Deming,[16] who found considerable decreases in vital capacity even in normal men who had been breathing high oxygen concentrations for prolonged periods. These studies again emphasize the complexities involved in treating a near-dead patient and the need for further and more careful evaluation of available technics.

SUMMARY

Quantitative data obtained on apneic, asphyctic patients cast grave doubt on the efficacy of the Schafer prone pressure method for producing artificial respiration.

Observations have also been made on the Eve tilting method and the intratracheal oxygen insufflation technic.

---

[10] It should be pointed out that there was *no greater* hindrance to outward diffusion of carbon dioxide than to inward diffusion of oxygen. The arterial oxygen saturation of 90 to 95.8 per cent was attained only by reason of the high oxygen tension supplied in the trachea: if air had been used instead of oxygen, very severe anoxia would have accompanied the high carbon dioxide levels.

Skull Fracture.—Depending on the velocity and size of the striking object, a local deformation may take place and the bone in the area of impact may fail with consequent localized circumscribed fracture and depression. In such a case there frequently occurs a separation of the inner and outer tables. The bone fails at the convexity of the border of the circumscribed area of bone which is deformed by the impact. This causes fracture by tension of the external table. The central portion of the area of deformed bone may fail internally, causing a fracture of the inner table. A separation of inner and outer tables may take place as one tends to slide over the other. A localized impact may dissipate itself in fracturing and depression without much transmission of energy to the skull contents. On the other hand, if an area of circumscribed depression is thrust into the cranial cavity by a severe impact, there may be a plunger effect with intracranial pressure increased and consequent pathologic and physiologic manifestations from distant lesions.—Gurdjian, E. S., and Webster, J. E.: *Experimental and Clinical Studies on the Mechanism of Head Injury*, in Trauma of the Central Nervous System, Baltimore, Williams & Wilkins Company, 1945.

THE INJECTION TREATMENT OF ESOPHAGEAL VARICES

CECIL O. PATTERSON, M.D.
and
MILFORD O. ROUSE, M.D.
Dallas, Texas

It is well known that recurring massive hemorrhage ultimately resulting in death often occurs in the patient who has untreated esophageal varices. As seen by x-ray examination and esophagoscopy, the bulbous venous projections into the esophageal lumen are daily subject to trauma from the swallowed bolus of food. Ulceration and rupture result in massive blood loss. Esophageal varices appear to serve no useful purpose that cannot be served by other and nonvulnerable anastomoses between the portal and systemic venous circulations. Our experience is that obliteration of these veins results in no appreciable unfavorable effects but rather that clinical improvement occurs soon after prevention of blood loss from the ruptured varix.

Experimental animals and other species than man have not provided the clinical syndrome in which the esophageal varix appears. Injection treatment had for years been considered, but it remained for two physicians, Paul Frenckner and Clarence Crafoord[1] of Stockholm, Sweden, in 1939 to report the first case in which esophageal varices were treated by injections of a sclerosing solution. There had been no recurrence of bleeding at the time of the report three years after the injection. In 1940 Moersch[2] reported the first case in this country in which the treatment was employed. He has later[3] reported other cases in which he has injected esophageal varices with a 2.5 or a 5 per cent solution of sodium morrhuate.

It has been our privilege to treat 12 patients (10 white male, 2 white female), the youngest 3 years of age, the oldest 66 years of age, injections being made into one or more veins. The patients have received at the most three or four injections at intervals varying from one week to one year. One patient's injections were done before and also after splenectomy. Four patients' injections were done after splenectomy, and 7 patients of older age were so treated in whom splenectomy has not as yet been done.

REPORT OF CASES

Case 1.—A white man aged 53, admitted to the Medical Arts Hospital, service of Dr. Merritt B. Whitten, had been unable to leave his bed for three months because of frequently recurring massive hematemeses. Frequent states of shock from blood loss had been treated by infusions of plasma and whole blood. With the diagnosis of cirrhosis of the liver, and huge abdominal ascites, he had had frequent abdominal paracenteses the previous eighteen months.

Esophagoscopy and injection of his esophageal varices were done by us at weekly intervals for four times in February 1944. He was up in a wheel chair six weeks later. He was soon ambulatory and discharged from the hospital. Six months after his injections his red cell count was 4,200,000 and he had continued ambulatory. In September 1944, seven months after his injection treatments, he had several recurrences of massive hematemesis from which he failed to survive. It was quite stimulating, however, that this patient with ascites and confined to his bed for three months because of esophageal varices which ruptured each time his red count came up to about 2,000,000, had quickly become able to be out of bed and his red cell count had rapidly returned to normal within a few weeks after the injection treatment of his esophageal varices.

Case 2.—A white boy aged 3 years, admitted to Bradford Memorial Hospital, service of Dr. John Dunlap, was diagnosed as having "splenomegalia, with massive hematemesis, probably Banti's syndrome." Recommended splenectomy and ligation of the coronary vein of the stomach were successfully done Oct. 30, 1943. Massive hematemesis recurred Sept. 15, 1943 and Feb. 11-14, 1944. Having had splenectomy, this small boy was considered an ideal subject for the best results by injection treatment of his esophageal varices. Esophagoscopy by one of us on February 17 visualized a large, bulbous, bluish red scarred vein projecting into the lumen of the esophagus just above the cardia, which was injected with 1 cc. of 5 per cent sodium morrhuate. There were only a few drops of blood loss from the needle puncture. Esophagoscopy was repeated February 26 and two other small veins near the cardia were injected. Fifteen months later, as a precautionary measure, esophagoscopy was repeated and two small veins were injected. There had been no evidence of blood loss during twenty-two months since the first injection treatment of his esophageal varices, although two massive hemorrhages requiring transfusions had occurred at six weeks' intervals prior to the injection treatment. He has a normal blood picture and has grown normally in weight and height.

Case 3.—A white man aged 65, admitted to the emergency medical service, Parkland Hospital, Oct. 21, 1944, was in a state of profound medical shock following massive hematemesis. An outpatient record stated that he had partaken of as much as a pint daily of alcohol for years. The history, physical examination, recent x-ray examinations and laboratory studies had justified the working diagnosis of cirrhosis of the liver with bleeding esophageal varices. Within six hours after admission he had received 2,000 cc. of whole blood; but fresh red and clotted blood had continued to roll out of his mouth, such that he showed no improvement, was semiconscious and was pulseless at the wrists, and death seemed inevitable.

With the help of capable house officers he was removed to the operating room while whole blood was being administered into the veins of both feet and one arm. At esophagoscopy by one of us a large bleeding varix was injected with a total of 6 cc. of 5 per cent sodium morrhuate. The patient was soon returned to his room, where the blood pressure was 114/80. The following morning he was sitting upright in bed sipping milk. About six months later, at the age of 66, he died of other causes, having had no recurrence of bleeding.

Case 4.—A white woman aged 33 was admitted to the medical service of Dr. Tinsley R. Harrison, Southwestern Medical College, Nov. 1, 1944, having had two weeks of recurring hematemesis. There had been nine similar episodes in the previous five years. As an outpatient in 1937 she had had jaundice during antisyphilitic therapy. On the present admission the spleen was palpable four fingerbreadths below the left costal margin. The red cell count was 1,480,000. Preparation of the patient for needed splenectomy was interrupted repeatedly by massive hematemeses.

Esophagoscopy by one of us on Nov. 29, 1944 revealed three large venous trunks in the lumen of the lower third of the esophagus. These were well injected. Thereafter the red cell count maintained a safe level after transfusions. The patient was transferred to the surgical service and removal of the spleen, which weighed 1,325 Gm., was accomplished December 9. The tissue diagnosis was "(1) portal cirrhosis, Laënnec's type; (2) extensive degree of chronic passive hyperemia of the spleen." The patient was discharged from the hospital two weeks postoperatively. On her return to the outpatient gastroenterologic service, Jan. 24, 1945, visible veins in the lower part of the esophagus were again injected, and the patient was admitted to the hospital for twenty-four hours. Report to the outpatient service on June 6, 1945 revealed a normal weight of 155 pounds (70 Kg.). There had been no recurrence of bleeding; there was normal ruddy skin.

From the Division of Gastroenterology, Department of Medicine, Southwestern Medical College.

We were called on by the physicians named to care for these patients. Surgeons and radiologists participated in the diagnoses and corrective surgical procedures.

Case 5.—A white man aged 40, a farmer, came to our office June 14, 1941 because of recurring massive hematemeses. For ten years he had had recurring "swelling of the abdomen and feet." In March 1938 he had vomited blood and had been admitted to a hospital, where he was told that he had cirrhosis of the liver. His abdomen had been tapped and a large quantity of fluid had leaked from the needle puncture wound, saturating his bed over night. There had been an area of "match box dermatitis" the size of the palm on his right thigh for many years.

To physical examination the spleen was palpably enlarged; there was shifting dulness in the abdomen. The hemoglobin was 23 per cent; the red cell count was 1,220,000. He was referred to the surgical service of the medical college, where splenectomy was successfully done July 9, 1941. At surgery he was found to have a very small nodular liver. In February 1945 he again came to our office because of massive hematemesis and swelling of the abdomen and feet. There was again a tightly distended abdomen, which to percussion was that of ascitic fluid. Esophagoscopy by one of us revealed extensive varices which almost filled the lumen of the lower half of the esophagus. Beginning at the cardia, the veins were injected every third day for three times, a total of 20 cc. of 5 per cent sodium morrhuate being given. After transfusions of whole blood and plasma he was discharged from the hospital and returned to work six weeks later. He has regained his normal weight of 146 pounds (66 Kg.); pallor, the large ascites and the edema of the feet have disappeared. It is noteworthy now that seven years have elapsed since his first massive hematemesis and ascites and that he is symptom free and that during the two years prior to this admission he had lost no time from his work as shipping clerk, ten hours a day, on a six day a week wartime job.

Case 6.—A white man aged 51 was admitted to the service of Dr. E. R. Cox, Baylor University Hospital, May 20, 1945, after recurring massive hematemesis. In December 1944 careful study by Dr. Cox had revealed "enlarged spleen of unknown etiology." Hemorrhage recurred and the hemoglobin reached 6.9 Gm. on the third day after admission. To esophagoscopy by one of us on May 26 several large venous sacculations were seen projecting into the lumen of the lower third of the esophagus. When suction was applied to clear away mucus from a vein just above the cardia, two small continuous streams of blood appeared. The vein was well injected but the bleeding continued. Quickly there was an estimated 300 to 400 cc. of blood loss. Finally a half-inch gauze pack was placed firmly against the bleeding vein and the ever grateful patient was returned to his bed. The pack was removed the following morning. Liquids were allowed that day, a soft diet was given the following day, and the patient was discharged on the fourth day after injection treatment. One month later he was ambulatory and had a normal ruddy skin; his ascites had disappeared. His spleen was still enlarged.

Case 7.—A white man aged 66 came March 26, 1945, having been referred to the gastroenterologic service, Southwestern Medical College, to have injection treatment of esophageal varices. There had been massive hematemesis in April, August and November of the preceding year, after each of which he quickly recovered following transfusions of whole blood. He had had typhoid thirty-six years before and had been told that he had an attack of coronary occlusion four years before the present admission. The patient was of slender build; the abdomen was flaccid and the spleen was palpable three fingerbreadths below the left costal margin. There were protruding hemorrhoids.

On admission the hemoglobin was 7.4 Gm. The icterus index was 1. A cephalin-cholesterol flocculation test at twenty-four hours was 3 plus, at forty-eight hours 4 plus. The sulfobromophthalein test revealed 66 per cent of dye retained fifteen minutes, 25 per cent thirty minutes, 8 per cent forty-five minutes and 5 per cent one hour. The Kline reaction was negative. At x-ray examination April 2 the admitting diagnosis of esophageal varices was verified. On April 4 esophagoscopy by one of us revealed the lower half of the esophagus occluded by multiple large veins. Three veins were injected, one each to the patient's right anterior, left anterior and right posterior, a total of 8 cc. of 5 per cent sodium morrhuate. There was an estimated 75 cc. blood loss. His esophageal veins were injected again April 11, 8 cc.; April 18, 10 cc. It was then thought that he had enough injections, but we were dubious of his recovery because of large gastric varices which appeared in the x-ray film and which were also visible to gastroscopy. The opinion of the surgical service, on repeated consultation, was that his 66 years and his general depletion contraindicated splenectomy or other corrective surgery.

At the conclusion of the injection treatments the hemoglobin was 8 Gm. There was recurrence of large hemorrhage April 24, 27 and 30 and May 3, 6 and 9, followed by gradual decline and demise May 11. At autopsy the pathologist, Dr. Charles T. Ashworth, reported that portal hypertension, with resultant esophageal varices, had evidently been the result of obstruction to the portal vein by a mass of scar tissue at the porta hepatis. The spleen weighed 1,095 Gm. There were multiple 1 mm. ulcerations of varices in the lower third of the esophagus, obviously the site of recent hemorrhage. There was no evidence of bleeding from the veins of the stomach. The gastric mucosa was quite smooth and intact, although large veins could be seen in the fundic portion of the stomach.

Case 8.—A white girl aged 17 was admitted to the service of Dr. Paul Thomas, Baylor University Hospital, Oct. 22, 1944, soon after a large vomitus of dark red clotted blood. Banti's syndrome had been diagnosed elsewhere and the patient had had splenectomy ten years before and an omentopexy eighteen months before. The patient, a college sophomore, appeared to be in excellent health except for moderate pallor; the pulse rate was 120, the temperature 102 F., the blood pressure 104/58, the height 5 feet 4 inches (162.5 cm.) and the weight 118 pounds (53.5 Kg.). On admission the hemoglobin was 6.9 Gm., red blood cell count 2,240,000, white blood cell count 16,200, 23 bands, 67 segmented and 13 lymphocytes. The clotting time was 55 seconds, the bleeding time 2 minutes and 30 seconds. The prothrombin time was 42 seconds, or 95.6 per cent of normal. Thirty-six hours after admission, esophagoscopy by one of us revealed multiple varices in the lower third of the esophagus. Scarring over the esophageal veins indicated the sites of former ruptures. Three prominent venous trunks in the lower part of the esophagus were injected with a total of 5.5 cc. of 5 per cent sodium morrhuate. The patient was discharged ambulatory four days after the injection of the varices. As a precautionary measure she was readmitted four months later and the veins were reinjected.

COMMENT

Esophageal varices, to direct inspection through the esophagoscope, are seen in some instances so large that they softly occlude the esophagus.

Several patients have complained that substernal and upper abdominal distress precede hematemesis such that the patient and the patient's family can predict the approaching catastrophe of hemorrhage. It appears, therefore, that persistent substernal distress occurring in a patient having known or suspected esophageal varices would indicate the need for x-ray study and probably esophagoscopy and injection of any veins large enough to produce symptoms.

We have noted that patient 3, in a critical state of shock immediately before the injection, appeared in no danger at all a few moments after the injection and was sitting upright in bed sipping milk ten hours later. It would thus appear safe to do the injection treatment after the patient is in the proper hospital environment with reasonable assurance as to the diagnosis and with adequate facilities, particularly typed whole blood, available. The contraindications to esophagoscopy should of course always be kept in mind.

In the instance of case 4, preparation for necessary splenectomy was repeatedly disrupted by massive hematemesis. Only after the injection of sclerosing solution into the esophageal varices did the hematemesis cease and the red blood cell count maintain a safe level for surgery.

As in case 7, hemorrhage appears not infrequently from esophageal varices but is most rarely proved to be from gastric varices. This fact, as Kegaries[4] showed, is best explained by the anatomy of gastric veins, which tend to be subserosal and are held more firmly by the less elastic structure of the stomach, while in the esophagus varicose veins tend to be submucosal and are held less firmly by the areolar tissues of the esophagus, tending to sacculation and protrusion into the lumen of the esophagus, where they are more vulnerable to ulceration and rupture.

From the foregoing, the ultimate evaluation of treatment of esophageal varices by injecting sclerosing solutions will have to await time and careful observation of these patients. It is true nevertheless that the results thus far observed tend surely to justify the procedure.

VENOUS THROMBOEMBOLIC DISEASE

LEO LOEWE, M D, PHILIP ROSENBLATT, M.D.
and EDWARD HIRSCH, M D.
Brooklyn

The active rational medical prophylaxis of pulmonary embolism by the use of heparin has been discouraged because of the involved technical procedures required for maintaining continuous anticoagulant effects. Although recent reports on the routine use of dicumarol have been promising,[1] the potential hazards, the unpredictable treatment failures and the requisite complicated laboratory controls do not make this drug the anticoagulant of choice.[2] The therapeutic attack up to the present has been based, for the most part, on the surgical interruption of the continuity of the clot-bearing vein or veins. Our purpose in this communication is to propose a safe, rational method of heparinization for the conservative treatment of thromboembolic disease which obviates previous objections to the use of this drug.

Recognition of the increasing incidence of venous thrombosis in the calf of the leg and in the plantar area has stimulated renewed interest in the problem of intravascular clotting. The statistical surveys of Nygaard[3] and others and the experimental and pathologic studies of Rossle,[4] Neumann[5] and Frykholm[6] have further emphasized the importance of venous thrombi in the pathogenesis of pulmonary embolism. Hunter, Sneeden, Robertson and Snyder[7] stress the fact that embolic phenomena may be the first sign of clinically silent phlebothrombosis of the deep calf veins.

The pathogenesis of intravascular clot formation in bland phlebothrombosis is imperfectly understood. Probably the most important single factor favoring thrombus formation in the lower extremities is the sudden confinement to bed of a previously ambulant individual, especially the thrombophile, without benefit of measures which favor the maintenance of an efficient venous circulation. The formation of clot in a small vein often is followed by its propagation into the larger venous channels. This propagation, especially in the immediate postoperative period, may well be explained by the increased platelet count, enhanced agglutinability or "stickiness" of the platelets, hemoconcentration, increased viscosity of the plasma, hyperglobulinemia and increased fibrinogen content.

It is a well established fact that a rise in the blood platelet count follows childbirth or a surgical operation, and this is believed to be a contributory factor in initiating postpartum or postoperative venous thrombosis. The increase begins about the fourth day after operation or delivery, attains its maximum about the tenth day and then tapers off, reaching normal by the twenty-first day. The period of hyperthrombocytemia corresponds roughly to the period in which venous thrombosis generally occurs. The correspondence, however, is not complete.

To account for this discrepancy, MacKay[8] and later Wright[9] postulated a second thrombogenic factor, an increased agglutinability or adhesiveness of the thrombocytes or blood platelets. This phenomenon also begins about the fourth day postoperatively or post partum and reaches its peak about the tenth day, when nearly 90 per cent of the platelets are adherent. The stickiness then gradually decreases and the platelets are restored to normal by the twenty-first day. For a more detailed discussion of etiology, reference should be made to the papers of Ochsner,[10] Ochsner and DeBakey,[11] Duryea,[12] Frykholm[6] and Bauer.[13]

The basic clot, composed essentially of platelets and leukocytes, represents the so-called white head on which is superimposed a collection of erythrocytes to form the friable red tail. As the blood clot grows, the soft red tail usually waves free in the vascular current. If the thrombus does not become detached, organization soon takes place with fibroblastic proliferation and firm adherence of the thrombus to the vessel wall followed by recanalization to a variable degree. If, however, the soft red clot breaks off and is carried into the swiftly moving vascular stream, it immediately becomes an embolus and causes pulmonary infarction. It is thus evident that, lacking precise knowledge of the initiating factor in thrombosis and, hence, a logical therapeutic

approach at the source, therapy must be confined to either an interruption of the vascular stream proximal to the site of clot formation or to rendering the blood incoagulable.

Division of thromboembolic disease into thrombophlebitis and phlebothrombosis is purely arbitrary, since elements of both may be present in any case of venous thrombosis. In the former, clotting is believed to be the result of alteration of the vascular endothelium from mechanical trauma, bacterial invasion or chemical injury, while in the latter it may be due to venous stasis or alterations in the cellular and fluid constituents of the blood.

Many postoperative and postpartum venous thromboses result from an infective initiating factor, with consequent thrombophlebitis. In these cases, diagnosis is relatively simple and is based on the presence of fever, local pain, swelling and tenderness. The changes in the vascular endothelium usually cause the clot to be firmly attached to the vessel wall. Such a clot is unlikely to become detached unless (1) a red clot formed proximal to the mixed thrombus is broken off (which occurs in 10 to 15 per cent of cases) or (2) suppurative liquefaction of the clot occurs with the production of infective emboli.

In bland phlebothrombosis, on the other hand, the clot is loosely attached to the vessel wall and consists in the main of a red clot which waves freely in the vascular stream. The onset of clotting is insidious, and the usual clinical features of inflammation are absent. Localized calf or plantar pain and positive calf tenderness on dorsiflexion of the foot, Homans' sign,[14] establish the diagnosis, which may at times be confirmed by phlebography. The value of the latter procedure, first introduced by dos Santos[15] and popularized by Bauer,[13] Fine[16] and others,[17] has been questioned because of the unpredictable results obtained by the technics in use. In practice it has been common experience that, when information was most urgently needed, the phlebograms were equivocal or uninformative. Unfortunately, at times the first evidence of phlebothrombosis may be an alarming or even fatal pulmonary embolization.

The surgical approach to the problem of thromboembolism was first initiated in America by Homans[18] and later elaborated by Welch and Faxon,[19] Fine,[16] Allen and his associates,[20] de Takats[21] and others. The knowledge that the majority of such emboli stem from the veins of the lower extremities led these investigators to divide the suspected vein, after preliminary thrombectomy, on the faintest suspicion of phlebothrombosis. Indications for vein ligation have been based for the most part on clinical signs, whether or not corroborated by positive phlebograms (Allen,[22] Ochsner[23]).

In the few years during which unilateral superficial femoral vein ligation has been practiced, it has become apparent that fatal pulmonary emboli may derive from an unsuspected thrombotic process on the contralateral side, so that bilateral superficial vein interruption has now become common practice. Even this procedure, the magnitude of which is unduly minimized by recent observers, does not offer absolute protection against embolization, although Allen[22] reports only 5 per cent of subsequent sublethal embolization following bilateral superficial femoral vein ligation, with no instance of a fatal embolus in 579 femoral vein interruptions. Nevertheless there are known fatalities in which the offending embolus originated from the profunda femoris vein proximal to the site of ligation of the superficial femoral vein. This has prompted Linton[22] to divide the common femoral vein. The resultant edema from this procedure has admittedly been troublesome and has been observed to persist for a year or two or longer. Since embolization from the profunda femoris may occur, Homans[24] has been impelled to advocate common iliac and even inferior vena cava ligation. However, Homans admits that technical difficulties militate against thrombectomy, particularly in a phlebothrombosis of long standing, so that ligation must of necessity be carried out in continuity, even if a clot is present proximal to the ligature. Obviously embolization from the proximal thrombus is not beyond the realm of possibility.

It must be stated that, although the majority of emboli derive from the peripheral veins, the initiating site may at times be the pelvic veins, for which surgical intervention, if it is to be effective, must perforce be a formidable procedure. Finally, in those cases of long standing thrombophlebitis, phlegmasia alba dolens, in which multiple infarcts have occurred, any surgical intervention short of vena cava ligation offers little prospect of cure.

It thus appears that the pendulum of surgical therapy has reached the peak of its swing and the relatively innocuous procedures of a few years ago are being supplanted by operations of considerable magnitude. In view of the failure to achieve a complete thrombectomy consistently in cases in which adherent clot was found far proximal to the phlebotomy or because of the hazard of subsequent postoperative embolizations, whether or not they are sublethal, Bancroft[25] has advocated the postoperative use of heparin. Indeed, Allen[22] admits that for patients with multiple infarcts heparinization has been used with definite benefit.

Although saving of life is the prime consideration of surgery, the resultant edema is most troublesome to the patient. Operative procedures which interrupt not only venous but also lymphatic channels contribute considerably to this edema. Admittedly, conservative treatment without heparin, consisting in the main only of bed rest and sedation, may occasion considerable edema in those who survive. In our experience the supplemental use of subcutaneous heparin results in minimal residual edema, certainly far less than that observed following operative intervention.

Briefly, it is apparent that the surgical approach, while efficacious in the majority of instances, has its limitations, although in all fairness it must be stated that a great number of lives have been saved which otherwise would have been lost if surgical interruption of the venous systems had not been practiced since no alternative conservative method of management has heretofore been generally available.

In reviewing the shortcomings of surgery for the treatment of thromboembolic disease, it is apparent that the anticoagulants assume prime importance. The properties of heparin which render it uniquely applicable in thromboembolic disease are that it prevents the formation of thromboplastin from platelets, it prevents, with the aid of a plasma cofactor, the conversion of prothrombin to thrombin, and finally it forms with serum albumin a strong antithrombin (Quick[26]). In other words, the continued formation of blood clot is inhibited by heparin, and repair of existing thrombi inevitably takes place at a more rapid tempo. It is evident that, regardless of the site of the thrombosis, heparin may be utilized because of its systemic effect. Its value in the prophylaxis and treatment of thromboembolic diseases has been established by numerous investigators, including Crafoord[27] and Murray.[28]

The routine use of heparin, however, has been limited by the expense, by the huge amount of drug required for the individual case and by the cumbersome method of administration, which requires a continuous venoclysis or repeated daily intravenous dosage. The restriction of motion of the patient, the almost absolute certainty that superficial angiitis would eventually occur at the site of injection and the haphazard control of the clotting time with these methods of administration render heparin therapy useless unless constant untiring supervision is available.

Eucupin dihydrochloride............	1.0	1.0	1.0	1.0
Pitkin menstruum, q. s..........ad	1.0 cc.	2.0 cc.	2.0 cc.	1.0 cc.

In an attempt to achieve prolonged absorption of heparin, pellet and capsule implantation in experimental animals was attempted. Erratic, unpredictable effects were observed. However, a slower and more equable distribution of heparin was obtained by incorporation of the drug in the Pitkin menstruum,[29] developed to regulate the rate of release of water soluble drugs injected intramuscularly or subcutaneously.[30]

The ingredients of the Pitkin menstruum are gelatin 15 to 30 per cent, dextrose 5 to 12 per cent, glacial acetic acid 0.5 per cent and sufficient distilled water to make 100 per cent. The rate of liberation of the contained heparin is inversely proportional to the viscosity of the menstruum; the optimum percentages of gelatin and dextrose were found to be 18 and 8 per cent respectively for the preparation containing heparin.

Heparin/Pitkin menstruum is a preparation of various amounts of heparin sodium salt, with or without vasoconstrictor drugs, dissolved in the Pitkin menstruum. This is done so that the dosage may be varied as indicated in the treatment of the individual patient. In general, the anticoagulant action of heparin sodium salt combined with vasoconstrictor drugs (in the menstruum) is more prolonged than the same amount of heparin sodium salt (in the menstruum) without vasoconstrictor drugs. In thromboembolic venous disease heparin with vasoconstrictor drugs is customarily employed. It is more advisable, however, to use heparin without vasoconstrictor drugs in thromboembolic arterial disease in order to eliminate the complicating factor of arterial spasm. This necessitates more frequent administration because of the more rapid depletion of the individual deposit.

The ampules which have been prepared for clinical use contain various amounts of heparin sodium salt, with or without vasoconstrictor drugs, and are as in table 1.

Body weight and individual reactivity dictate the amount of heparin/Pitkin menstruum to be used in a given case. For the initial injection, body weight is used as a guide. Patients weighing up to approximately 150 pounds (67.8 Kg.) should be given an initial dose of 300 mg. of heparin sodium salt; patients over this weight should be given an initial dose of 400 mg. Subsequently the dosage should be adjusted according to the intensity of the "heparin effect" as estimated by the coagulation time.

Any desired dose of heparin, with or without vasoconstrictor drugs, can be given by combining the contents of two or more ampules. It has never been necessary to employ more than 400 mg. of heparin for any single deposit. This dose is arrived at by combining two ampules, each containing 200 mg. of the drug. When ampules which contain the vasoconstrictor drugs are used, not more than one such ampule should be included in a combination of ampules administered in one single injection.

METHOD OF ADMINISTRATION OF HEPARIN/PITKIN MENSTRUUM BY SUBCUTANEOUS INJECTION

1. Warm the ampule(s) gently by immersing in a glass of hot tap water until the contents become fluid.
2. Shake well to disperse any precipitated material.
3. Draw the contents into a sterile 5 cc. or 10 cc. syringe, using a sterile needle, gage 18, of 2 inches length. After the syringe has been filled, attach a sterile needle, gage 19 or 20, of 2 inches length, for the actual deposition.
4. Inject the contents immediately into the deep subcutaneous tissues, preferably in the anterior or lateral aspect of the thigh. When more than one subcutaneous deposit is required, use the right and left thighs alternately and avoid sites of previous injections. Do not inject into sites where pressure may be exerted on the injection area.
5. Be certain that the contents of the syringe are not too hot prior to the injection. The syringe and contents should feel only slightly warm.
6. Do not apply either heat or cold to areas of deposition at any time.

Use the entire contents of the ampule(s) (300 mg. heparin sodium salt for the average individual). This dose should be sufficient to keep the patient heparinized for at least two days. If the patient must be heparinized for a longer period, administer the 300 mg. every second day throughout the requisite period. After two or three deposits on this dose schedule it may be possible, if the patient's response warrants it and if the coagulograms are satisfactory, to space the remaining implants every third day. If the patient receives a blood transfusion during the period of heparinization, administer a standard dose of 300 mg. immediately following the transfusion, irrespective of when or how many previous deposits have been given.

METHOD OF FOLLOWING THE PATIENT'S CLINICAL COURSE

The effect of heparin is judged by and based on determination of the blood coagulation time, which should be done at least once a day during the period of heparinization. Determination by means of the capillary tubes is totally inaccurate and should not be used. A modification of the Lee-White method [31] for determination of blood coagulation time is recommended. The procedure is as follows:

1. Place four chemically clean dry 75 by 10 mm. test tubes in a rack.
2. With a sterile dry syringe and needle withdraw a little less than 2 cc. of venous blood from the heparinized patient.
3. Distribute a little more than 0.35 cc. of blood into each test tube and allow the tubes to stand until the test is completed.
4. The test is timed by stop watch from the moment the vein is negotiated to the time clotting is noted in the test tubes. The normal values usually range from nine to fifteen minutes.

SUGGESTIONS AND PRECAUTIONS

1. All glassware, syringes and needles must be absolutely dry. Moisture, alcohol and other substances invalidate the determination.
2. The vein must be cleanly negotiated. If difficulty is encountered, it is best to use a fresh needle and syringe. Even a small amount of tissue juice aspirated into the syringe will give a fallacious result.
3. Once the blood is placed in the test tubes, they must be disturbed as little as possible while observing for the end point. It will be noticed that well heparinized blood will sediment very rapidly. The tube should not be shaken after sedimentation of the blood. Look for clotting in the red cell layer as well as in the plasma layer by gently tilting the tubes. In unclotted blood the red cell layer will flow slowly as the tube is angled.
4. If clotting occurs at different times in the various tubes, average the three closest figures.
5. Excessively high coagulation times—over an hour—are unnecessary and indicate waste of the anticoagulant drug.
6. The effect of a single therapeutic deposit should last for forty-eight hours or more. Satisfactory results have been attained over protracted periods (five weeks) with as little as 2,300 mg. of heparin. At least 10,500 mg. would have been required to achieve the same results with intravenous commercial aqueous heparin had it been feasible to administer it over such a long span of time.

REACTIONS AND COMPLICATIONS IN THE USE OF HEPARIN/PITKIN MENSTRUUM: THEIR TREATMENT

1. Following the administration of LP-0, LP-8, LP-9 and LP-12 (ampules containing vasoconstrictor drugs) the patient will occasionally complain of palpitation and nervousness. These reactions require no treatment and disappear within a short time.
2. Digitalis inhibits the anticoagulant action of heparin. Avoid the use of this drug during periods of heparinization.
3. Intragluteal administration may be employed with perhaps less local discomfort, but absorption is too rapid. An important advantage of the subcutaneous approach is that the anticoagulant effect may be considerably retarded or accelerated by the application of ice bags or heat, respectively, to the site of injection; it may be suspended altogether by means of prolonged local refrigeration and/or pressure above and below the site, together with adjunct measures such as the transfusion of fresh whole blood or globin injections.
4. The administration of subcutaneous heparin/Pitkin menstruum is accompanied by a variable degree of fever, and pain, swelling and tenderness at the site of inoculation. These discomforts, due primarily to the subcutaneous deposit of heparin,[32] are usually not excessive, but adequate sedation should be prescribed. Even when more pronounced, these disadvantages of the subcutaneous administration are far outweighed by the benefits of the treatment and the added comfort of knowing that with the subcutaneous route the rate of release of the drug is under control at all times.

RESULTS; ANALYSIS OF CASES

The original publication [33] reported 15 cases of thrombophlebitis or phlebothrombosis successfully heparinized by this method. The series of 125 cases,[34] presented in table 2, which is the subject of the present report, represents virtually all the types of venous thromboembolic disease. Some of the categories have afforded more cases than others, but on the whole there are a sufficient number of cases for purposes of observing and evaluating the clinical deportment of subcutaneous heparin in thromboembolic disease. The results have been most gratifying, being signally successful in thrombophlebitis irrespective of etiology (cases 5, 7, 8, 9, 10 and 11). The criteria of satisfactory response are the rapidity of subsidence of edema, prompt improvement in pain and discomfort, reduction in morbidity and the degree of residual edema, and the clinical behavior in the presence of pulmonary embolization.

Table 2.—*Composite of All Cases of Venous Thromboembolic Disease Treated with Subcutaneous Heparin in the Pitkin Mentsruum*

Classification of Thromboembolic Disease	Number of Cases	Statistics of Pulmonary Embolism		
		Number of Cases	Deaths	
			Number	Percentage
Thrombophlebitis and/or phlebothrombosis, postoperative	46	14	2	14+
Thrombophlebitis, thrombophiles, carcinoma, varicose veins, etc.	32	13	0	0
Thrombophlebitis and/or phlebothrombosis, venous ligation	13	9	1	11+
Thrombophlebitis, postpartum	14	3	0	0
Thrombophlebitis, postinfectious	9	0	0	0
Thrombophlebitis, post-traumatic	6	3	1	33+
Thrombophlebitis, migrans	5	0	0	0
Total	125	42	4	9.5

The final judgment in any treatment program for thromboembolic disease is predicated on the statistics with respect to pulmonary embolization. The detailed clinical data relative to pulmonary embolization in this series of 125 cases will be made the subject of a comprehensive report. It is noteworthy however that, of the 125 patients, 42 had from one to six pulmonary embolizations prior to initiating subcutaneous heparin therapy. There were four fatalities in this series of 42 cases, or

[33] Loewe, L., and Rosenblatt, P.: A New Practical Method for Subcutaneous Administration of Heparin: Preliminary Report, Am. J. M. Sc. **208:** 54, 1944.

[34] This series of cases was recruited mostly from the Departments of Surgery, Medicine, Gynecology and Obstetrics of the Jewish Hospital, Brooklyn.

9.5 per cent. Brief comment concerning these four deaths is essential in order to gain proper perspective regarding this aspect of our problem. Two of the fatalities came early in our experience and served as an *object lesson for standardizing and formulating our present program of therapy and dosage schedules* (case 1). The third occurred in an obese woman who developed thrombophlebitis with pulmonary emboli following mastectomy for advanced massive carcinoma. This is considered a treatment failure although the patient was in profound circulatory collapse throughout the entire postoperative period and there was some doubt as to the cause of death, no necropsy being performed. The fourth fatality followed sequential femoral vein ligation for recurrent pulmonary embolization incidental to postoperative phlebothrombosis. Subcutaneous heparin was discontinued prematurely two days after the initial left femoral ligation because the pulmonary findings were attributed to virus pneumonia, which was prevalent at the time. The right femoral vein was ligated about ten days after the left femoral vein ligation. Lethal pulmonary embolization followed the third day after the right femoral vein ligation; necropsy disclosed old adherent thrombi in the left iliac and left hypogastric veins which were probably the source of the emboli found occluding the right pulmonary artery and main branch of the left lower lobe. This case must be catalogued as a treatment failure for both thrombectomy and vein ligation and supplemental subcutaneous heparin therapy, although the latter was suspended after much too short a span of treatment. As an offset to these treatment failures mention may be made of 4 patients with multiple pulmonary emboli despite vein ligation with complete recovery following the use of subcutaneous heparin preparation (case 4).

A particularly significant and informative group consisted of the 9 patients who were successfully treated with heparin in the Pitkin menstruum following single or multiple massive pulmonary embolizations without any manifestations of peripheral vein involvement; these patients could not conceivably be subjects for proximal vein ligation (case 3). Finally, it is worthy of comment that in 5 patients subcutaneous heparin was successfully employed following failure with dicumarol and/or aqueous heparin by vein (case 6).

Case 1.—*Postoperative femoral phlebothrombosis with multiple pulmonary emboli; apparent excellent response to subcutaneous heparin; anticoagulant effects had disappeared when patient was allowed out of bed; lethal pulmonary embolus.*[35]

N. S. W., a white man aged 46, had a subtotal gastrectomy performed for gastric ulcer with carcinomatous degeneration. The postoperative course was complicated by phlebothrombosis of the left lower extremity, which was followed by two episodes of pulmonary infarction, corroborated roentgenographically. The patient was treated with subcutaneous heparin and given four injections totaling 1,200 mg. of heparin over a period of eleven days. The clinical signs in the left lower extremity subsided and the patient was allowed out of bed four days after the last heparin deposit. In the process of getting out of bed he suffered a massive pulmonary embolization and died.

The unfortunate outcome in this early case served as an object lesson. It was apparent that the patient should not have been allowed out of bed prematurely and at a time when he was not actively heparinized. Cases of phlebothrombosis with pulmonary infarction require periods of heparinization longer than the ten to fourteen days usually sufficient for uncomplicated venous thrombosis. Subsequent patients in this category were therefore mobilized after a *minimum* three week span of treatment and during the stage of active heparinization. With this program the results have been signally successful.

Case 2.—*Postoperative bilateral phlebothrombosis successfully treated with subcutaneous heparin.*

H. B., a white man aged 52, was admitted to the Jewish Hospital of Brooklyn on Jan. 31, 1943 with a diagnosis of perforated peptic ulcer. This was operated on immediately and primary closure was performed. On February 8 the patient had an evisceration, which was reduced under general anesthesia. On March 6 he developed a bilateral phlebothrombosis of the deep femoral veins. He was treated with heparin, which was administered by the subcutaneous method. He was given a total of 1,200 mg. of the drug in six deposits over a period of fourteen days. The patient made a complete and uneventful recovery without sequelae.

This was a case of simple phlebothrombosis following a surgical procedure. A two weeks course of treatment with subcutaneous heparin was sufficient to control the thrombotic complication despite its bilateral distribution.

Case 3.—*Multiple postoperative pulmonary infarctions without evidence of peripheral phlebothrombosis; unsuccessful outcome with conservative management and intravenous heparin; successfully treated with subcutaneous heparin.*[36]

C. L., a white man aged 26, had an appendectomy for acute appendicitis. Eight days postoperatively he suffered a right pulmonary embolization followed by bloody expectoration. He was treated conservatively with bed rest, sedatives and oxygen. Sixteen days after operation there was another episode of pulmonary embolus with radiographic signs of right lung infarction. The following day intravenous heparin was instituted, 200 mg. daily being given by continuous drip. During this period there were febrile reactions necessitating frequent interruptions of the venoclysis. On the thirty-first postoperative day phlebitis of the left arm and foot of the regional angiitis variety was noted. This progressed despite the intravenously administered heparin. On the thirty-fifth postoperative day there was another massive pulmonary infarction while intravenous heparin was still being given. The following day subcutaneous heparin therapy was instituted. A total of 1,600 mg. of heparin in five doses was deposited over a period of sixteen days. The patient responded satisfactorily and was allowed out of bed while still actively heparinized. He was discharged from the hospital without further trouble and has remained asymptomatic.

Of significant interest in this case was the fact that three massive pulmonary infarctions occurred without evidence of thrombotic disease in the lower extremities other than the superficial processes due to the continuous venoclysis. This case illustrates the almost certain futility of proximal venous ligation, since it was impossible to know where the emboli originated. Furthermore, the success attending the use of subcutaneous heparin is in direct contrast to the failure of the aqueous preparation when given by vein.

Case 4.—*Postoperative thrombophlebitis of recurrent and migratory character; bilateral saphenous vein ligations with postligation pulmonary embolizations; thrombophlebitis of the left femoral system successfully treated with subcutaneous heparin.*[37]

E. S., a white married woman aged 35, a registered nurse, was admitted to the Jewish Hospital of Brooklyn with a history of hysterectomy for fibroid uterus seven months previously at Misericordia Hospital, New York. Postoperatively she developed a right saphenous thrombophlebitis and was kept in bed for six weeks. Two weeks after discharge she developed a left saphenous thrombophlebitis. This subsided, but thereafter recurrent bouts of phlebitis took place until three months prior to admission, when first one and then the other saphenous vein was ligated. Following the second ligation she suffered several episodes of pulmonary embolization. With conservative management the lungs gradually cleared and she was discharged from the hospital. Several days prior to admission to this hospital she developed a severe thrombophlebitis involving the deep left femoral system. She was treated with subcutaneous heparin and received a total of 1,800 mg. in six doses over a period of fourteen days. She was discharged on the twentieth hospital day and has remained well to date, eighteen months after therapy.

This case is of particular interest since the prophylactic vein ligations prevented neither subsequent pulmonary embolization nor the formation of fresh thrombi in the deep femoral system of veins. Therapy with subcutaneous heparin abruptly interrupted the migratory and recurrent character of the disease, and the patient has remained well.

Case 5.—*Initial, clinically obscure, thrombophlebitis with migration and pulmonary infarctions; bilateral femoral vein ligations with postligation heparinization.*[38]

N. G., a white woman aged 50, a physician's mother, began to complain of pain in the left calf region three weeks prior to admission. Two weeks later there was swelling of the left leg. On the day of admission there was a sudden onset of shortness of breath associated with pain in the left side of the chest made worse by deep inspiration. There was no hemoptysis. The patient was treated expectantly. Although repeated examinations were made, a definite diagnosis of thrombophlebitis was not possible. During the fourth hospital week there was a sudden rise in temperature unassociated with physical findings. During the sixth hospital week there was a definite pulmonary episode. The week previously the patient had been complaining of aching pain throughout the right leg, but physical findings had been negative. At this time it was decided that the patient had a bilateral femoral thrombophlebitic process with multiple pulmonary infarctions. X-ray and electrocardiographic evidence indicated that there had been at least three such episodes. Phlebograms were attempted but were unsuccessful. It was decided that a bilateral femoral vein ligation be done. At operation Dr. G. P. Pennoyer found the left femoral vein to be completely thrombosed and the right thrombosed and partially organized. Because of the proximal extent of the thrombotic process it was thought that operative interruption of the continuity of the veins would probably not suffice. Accordingly, ten hours following the procedure the patient was started on subcutaneous heparin therapy. She was given a total of 1,500 mg. of heparin over a period of twenty-three days in five deposits. At the end of this time she was allowed out of bed. On being allowed to walk about, she noticed swelling of both legs; but this was controlled somewhat by the use of elastic stockings.

The importance of this case lies in the fact that bilateral femoral ligation was not considered sufficient to prevent the possibility of future pulmonary embolization. Despite the surgery, therefore, adjuvant therapy with subcutaneous heparin was necessary to treat this patient successfully.

Case 6.—*Postoperative and traumatic thrombophlebitis; unsuccessful prophylactic administration of dicumarol and intravenous heparin; prompt response to subcutaneous heparin.*[39]

J. M., a Negro aged 37, underwent a right inguinal herniorrhaphy. During the course of the operation the femoral vein was punctured and it bled freely. Bleeding was controlled by packing followed by dissection below the inguinal ligament, where pressure on the femoral vein was applied. The rent was then closed without difficulty by means of several fine silk sutures. Postoperatively dicumarol was given by mouth and heparin by continuous intravenous drip, with satisfactory prolongation of the coagulation time. Dicumarol was continued for eight days with no change in the prothrombin time. On the sixth, eighth and thirteenth postoperative days subcutaneous hematomas were aspirated from the upper end of the wound. On the fourteenth postoperative day the patient developed a typical and massive thrombophlebitis of the right lower extremity. Two days later therapy with subcutaneous heparin was begun. He received a total of 1,200 mg. of heparin given in three doses over a period of ten days. The obvious diminution of swelling and tenderness on the second day were remarkable, and the temperature subsided on the ninth day. He was discharged on the forty-third postoperative day in excellent condition.

This case was noteworthy because of the failure of dicumarol and intravenous heparin to prevent the formation of a clot in a femoral vein accidentally injured during herniorrhaphy. Despite this evident thrombotic tendency, the response to subcutaneous heparin was prompt and sustained.

Case 7.—*Postcesarean section; left femoral vein thrombophlebitis successfully treated with subcutaneous heparin.*[40]

B. E., a white woman aged 30, primipara, secundigravida, had an elective cesarean section on June 14, 1944. Thirteen days later she developed an acute thrombophlebitis of the left femoral vein. Symptoms and signs increased in intensity during the next three days, and therapy with subcutaneous heparin was begun on the sixteenth postoperative day. She received a total of 1,100 mg. of heparin over a period of ten days in eight doses. She responded rapidly and was allowed out of bed on the tenth day of treatment and was discharged well several days later.

Table 3.—*Measurements of Extremities in Case 9*

	April 27		May 16	
	Right	Left	Right	Left
Ankle	19.7 cm.	22.2	19.0	20.0
Calf	30.2	33.4	27.0	28.6
Thigh	48.5	58.7	47.0	48.3

Case 8.—*Postpartum unilateral phlegmasia alba dolens successfully treated with subcutaneous heparin.*[41]

L. R., a white woman aged 25, developed a massive thrombophlebitis of the left lower extremity three weeks post partum. She was given a total of 1,500 mg. of heparin in five injections over a period of ten days. At the end of this time local symptoms had subsided and measurements of the lower extremities, which initially showed decided disproportion, were now equal. She was discharged on the fifteenth hospital day.

Of interest in this case was the rapid resolution of the thrombotic process in the left lower extremity. With the customary conservative management it can be stated with little fear of contradiction that the patient, barring complications, would have been bedridden for from four to six weeks with a protracted massive residual edema. As in this instance, it is possible to render these patients ambulatory without appreciable edema in two weeks with the use of subcutaneous heparin.

Case 9.—*Thrombophlebitis, postinfectious, successfully treated with subcutaneous heparin.*[42]

A. G., a white youth aged 17, developed enormous swelling of the entire left lower extremity and abdomen, with tenderness and pain over the iliofemoral system of veins, two weeks following recovery from measles. Subcutaneous heparin therapy was started on the fourth day after the onset of the thrombophlebitis and continued for twenty-one days. This required ten deposits totaling 4,000 mg. of heparin. Measurements of the extremities portray the improvement (table 3).

This patient was discharged with very little residual edema. A remarkable feature of the case was the rapid response to therapy when consideration is given to the massive thrombotic involvement of the lower extremity.

CASE 10.—*Post-traumatic migratory thrombophlebitis with repeated episodes of pulmonary embolization successfully treated with subcutaneous heparin.*[43]

B. G., a white man aged 50, was admitted to the Jewish Hospital of Brooklyn because of thrombophlebitis of the right lower extremity with onset two and one-half weeks following trauma to the leg. Bed rest was instituted, but there were repeated episodes of pulmonary embolus. Approximately one month after hospitalization there was a sudden attack of pain in the left calf associated with tenderness, swelling and a positive Homan's sign. The diagnosis of left calf vein thrombophlebitis was made. It was decided at this time to give subcutaneous heparin, since expectant treatment had been a failure. The patient was given 1,800 mg. of heparin over a period of twenty-one days in seven deposits. He was discharged from the hospital clinically well.

This case represents an intractable, progressive variety of thrombophlebitis following trauma, with episodes of pulmonary embolus. Conservative management was thoroughly unsatisfactory, since it prevented neither embolization nor migration of the clot. The response to subcutaneous heparin was rapid and apparently permanent.

CASE 11.—*Recurrent migratory phlebitis successfully treated with subcutaneous heparin; no recurrence in two years.*[44]

N. S. R., a white man aged 48, a physician, had had attacks of migratory phlebitis over the past eighteen years. The attacks recurred every one or two years. In 1942 he had a right saphenous vein ligation performed. Two weeks prior to admission to the Doctors Hospital, New York, on Oct. 21, 1943, he had a recurrence of phlebitis involving the veins of the median aspect of the left leg. He was given a total of 1,700 mg. of heparin by the subcutaneous route in five injections over a period of fifteen days. He was discharged asymptomatic and has remained well to date.

This case is of interest because the patient, a physician, had been treated in the past by all known methods. His response to subcutaneous heparin was prompt and apparently lasting. Similar cases treated subsequently have consistently shown the same rapid improvement.

COMMENT

It is evident from a critical review of the cases (table 2) that a comprehensive trial of subcutaneous heparin in the Pitkin menstruum has been carried out with good results. While other expedients, such as sulfonamides and penicillin, may be used in conjunction with it, heparin alone in clinically established thrombophlebitis irrespective of etiology is attended with consistent beneficial, if not dramatic, results. These include diminution of temperature, pain and swelling, which often become manifest within a few hours after initiation of therapy. This improvement is predicated on the limitation in the progress of the formed thrombus, while the original inflammation expends itself and the thrombus either resolves or becomes organized. Since there is no further actual propagation of thrombus, there is a rapid and well defined diminution in vasospasm. In all cases morbidity is lessened and convalescence accelerated. It is felt that prolonged, deforming and incapacitating edemas are further prevented in these patients by blocking the deposition of fibrin in the perivenous lymphatics. In unsuccessful cases of vein ligation followed by pulmonary embolization in which the subcutaneous heparin therapy has been effective, the preparation has also aided materially in diminishing the subsequent lower extremity edema.

Failures have been due to an insufficient knowledge of the behavior of thromboembolic disease either during or immediately after heparin therapy. These failures occurred early in our experience, and the lessons learned have contributed materially to the present success of the method. In uncomplicated phlebothrombosis, heparinization need be continued only for ten to fourteen days, while cases complicated by pulmonary infarction, either single or multiple, require three to four weeks of continuous heparinization. The full heparin effect must be present when the patient is first allowed out of bed. These criteria are based on an expanded clinical experience.

We are aware of the fact that the surgical approach to the problem of thromboembolism aims at the disruption of continuity of the vascular stream between the most proximal tip of the clot and the cardiopulmonary area. We also know that the bulk of evidence suggests the lack of influence of heparin on preformed clot. Nevertheless, in our clinical experience we have had no instance of pulmonary embolus in the presence of adequate heparinization by the subcutaneous method.

Experiments are now in progress to determine the mutations of intravascular pathologic changes and the fate of the clot following subcutaneous heparin in order to correlate the morbid process, dosage schedule, span of treatment and other essential aspects of the therapeutic program.

After the institution of heparin therapy the liberal use of papaverine is recommended, ½ to 1 grain (0.032 to 0.06 Gm.) every four hours intramuscularly or even intravenously and, later, maintenance dosages by mouth. Smoking is strictly prohibited. Paravertebral block, although used extensively in arterial occlusions, is not used by us in thrombophlebitis as a routine measure, since we have found that venous spasm disappears promptly following administration of subcutaneous heparin.

Although truly comparative statistics of subcutaneous heparin and proximal vein ligation are not available, our roster of cases includes failures after vein ligation which were brought to a successful termination by heparin. As has been described earlier in this paper, the general systemic anticoagulant effect of heparin seems to us to be a more rational therapeutic weapon than local vein ligation, especially when the precipitating cause of thrombosis is not yet known and the initiating site of thrombosis can be ascertained in many cases only by vague and indeterminate clinical signs. The patient with phlebothrombosis is in a potentially precarious state in which additional manipulative and operative measures may induce embolization. The ready availability of immediate adequate and rational conservative treatment without moving the patient has caused vein ligation to be supplanted by subcutaneous heparin therapy in our clinic.

SUMMARY AND CONCLUSIONS

The treatment of venous thromboembolic disease with subcutaneous heparin in the Pitkin menstruum was attended with lessened morbidity, prompt and rapid clinical improvement, and little or no residual edema.

Treatment failures with other methods have subsequently ended in recovery following the routine administration of heparin in the Pitkin menstruum.

As a result of observations of its clinical deportment in 125 consecutive cases of thrombophlebitis and/or phlebothrombosis, the subcutaneous administration of heparin in the Pitkin menstruum is recommended as a safe, simple, practical and effective method for the conservative treatment of venous thromboembolic disease.

STREPTOMYCIN TREATMENT OF TULAREMIA

LEE FOSHAY, M.D., and A. B. PASTERNACK, M.D.
Cincinnati

Since a published report,[1] together with unpublished work by ourselves and our associates, demonstrated that streptomycin exerted both bacteriostatic and bactericidal effects on Bacterium tularense in low concentrations in vitro, as well as definite curative properties for the experimental disease in rodents, this study was undertaken to determine the effectiveness of streptomycin therapy in human tularemia.

Seven patients were treated. Each had been infected by handling wild rabbits. All presented symptoms typical clinically of tularemia, and each developed specific serum agglutinins to 1:320 or higher. The causative agent was cultivated after mouse inoculation of primary lesion exudate from the first, third, fourth and fifth patients. The days of disease on which streptomycin therapy was instituted were the eighth, twenty-third, third, seventeenth, twentieth, fiftieth and one hundred and third respectively.

EVIDENCES OF MODIFICATION OF THE NATURAL COURSE OF DISEASE

The best objective criteria whereby changes from the usual course of disease may be detected are the number of days of temperature above 98.6 F., the duration of buboes and the number of bedridden days. Usually less useful for small groups are the durations of disease and of disability, and the number of days required for healing of ulcerated primary lesions. In the present series, however, the duration of primary lesions became important. Although the number of patients is too small for numerical comparisons, it is well to remember that the disease usually causes thirty-one days of fever, thirty-one days in bed, a duration of disease of four months characterized by buboes for 3.5 months, disability for 3.5 months, and a healing time for primary lesions of thirty-nine days.

PREPARATION OF STREPTOMYCIN

All streptomycin except a portion of that given to the seventh patient was from a single lot containing 150 units per milligram. Since this early lot had not been tested for sterility or for pyrogens, we dissolved accurately weighed amounts in sterile salt solution so that each 4 cc. dose would contain the desired unitage, adjusted the p_H to approximately 7.0, filtered the solution through Berkefeld N filters, and bottled it aseptically in slightly more than 32 cc. amounts, one bottle for each day of treatment.

STREPTOMYCIN ADMINISTRATION

The most frequently used dosage, 30,000 units every three hours intramuscularly for five days, was tentative and wholly arbitrary, based on available in vitro and in vivo experiences and on the sensitivity of Bacterium tularense in relation to that of other disease agents for which some knowledge of clinical dosage was at hand.

TOXICITY CONTROL STUDIES

In anticipation of possible toxic effects of streptomycin, fluid intake and urinary output were measured daily, urinalyses for albumin, casts and red blood cells were made daily or more frequently, blood nitrogen determinations were made every other day during drug administration, and estimations of hemoglobin, total red blood cells and white blood cells and differential leukocyte counts were made irregularly. Daily observations were made for possible dermal and psychic changes. This was routine for all patients. Since no evidence for drug toxicity was noted, reference to these observations will be omitted hereafter.

REPORT OF CASES

Case 1.—*History.*—A. C., a man aged 33, was exposed on Nov. 12 and 18, 1944. Onset occurred on Nov. 23, 1944, with chills, fever, sweats, arthralgias, myalgias, anorexia, headache, mental dulness, photophobia and a painful swelling at the edge of the right thumb nail followed in two days by a tender swelling in the right axilla.

The patient was admitted to the hospital on the fourth day of disease with persistence of initial complaints and symptoms. The significant physical findings were a temperature of 101.7 F., a nonulcerated papular paronychial lesion on the right thumb and a painful, tender bubo measuring 1.5 by 1 cm. in the right axilla. Pneumonia was not present by physical signs or by x-ray.

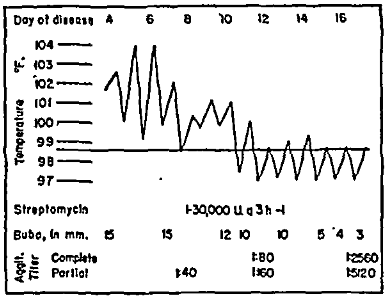

Fig. 1 (case 1).—Effect of streptomycin on the daily maximal and minimal temperatures and on the diameter of the accessible axillary bubo. Although the last recorded agglutinin titer is unusually high for the seventeenth day of disease, it is within the normal range and probably unrelated to the therapy.

An intradermal test with 0.05 cc. of a formaldehyde killed bacterial suspension on the fourth day of disease, the test dose containing about 6,000 cells, gave a positive reaction forty-eight hours later. Serum agglutinin titers are shown in figure 1.

Therapy.—Streptomycin administration was begun on the eighth day of disease, 30,000 units being given every three hours intramuscularly for five days, a total of 1.2 million units.

Course During and After Therapy.—At the end of the first day the patient looked and felt improved; headache was almost gone, the bubo and primary lesion were less painful, bodily aches and pains were ameliorated; he was not sweating but was interested to know when he could get up. By the second day he had had the first good night's sleep, with but one sweat, and awoke with a clear head. The bubo was almost painless, scarcely tender to pressure and distinctly smaller. Its previously smooth, tense surface was soft and rugose. The positive skin test reaction remained unchanged. By the third day the bubo was painless and still shrinking. The entire area of the primary lesion was wrinkled. On this day, the eleventh of disease, he stated that he had "no complaints whatever." During the next day he was afebrile. The bubo continued to dwindle, and the incised papule showed primary healing without ulceration. Recovery ensued rapidly without interruptions. The primary lesion healed without ulceration, and the bubo shrank to barely palpable size. He regained strength and vigor, was

Dr. W. A. Altemeier furnished the opportunity to collaborate in the treatment of case 2, Drs. Altemeier and A. F. Rewwer of case 4, Dr. D. A. Tucker Jr. of case 6 and Drs. R. L. Crawford and C. G. Reid of case 7.

[1] Heilman, F. R.: Streptomycin in the Treatment of Experimental Tularemia, Proc. Staff Meet., Mayo Clin. **19**: 553 (Nov. 29) 1944.

out of bed on the sixteenth day, the eighth after onset of therapy, and left the hospital on the eighteenth day of disease, afebrile and asymptomatic except for slight weakness. He returned to half time work in ten days. After two weeks he resumed full time work. During the subsequent eleven months he has remained well.

The patient had thirteen days of fever, fifteen days in bed and a palpable bubo for sixteen days. His primary lesion, although incised, had healed within seventeen days without ulcerating. He was totally disabled for twenty-eight days, with partial disability extending to 1.4 months from onset.

Case 2.—*History.*—M. E. T., a man aged 40, was exposed on Nov. 10, 11 and 12, 1944. *Onset occurred on November 15 with general malaise, anorexia and a "thorn" in the right thumb.* Three days later he had *severe chills, high fever,* drenching sweats, a splitting headache, lethargy, mental depression, *profound anorexia,* cough, nausea and vomiting. This condition persisted unabated for *fourteen days.* Since then he has had no chills but persisting low fever, cough, daily sweats, *dull headache,* lethargy and profound weakness with a *17 pound (7.7 Kg.)* loss in weight.

The patient was admitted with these residual complaints on the *twenty-second day of disease. Examination* revealed a temperature *of 99 F.,* evidence of recent loss of weight, a papulovesicular exanthem over the back of the neck and the shoulders, a painful *granulating ulcerated primary lesion* about 9 mm. in diameter on the middle phalanx of the right first digit and two tender dermal lymphangitic *nodules on the mesial surface of the right arm* with reddened *overlying* skin, the larger measuring 1 by 0.5 *cm.,* the smaller 0.4 *cm. Pneumonia* was *not present by physical* signs or by x-ray.

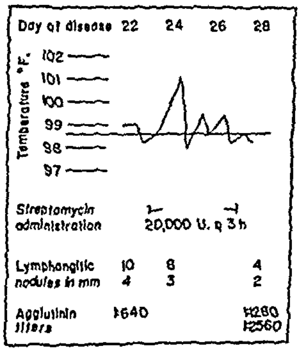

Fig. 2 (case 2).—Effect of streptomycin *on* the temperature curve and on the diameters of the dermal lymphangitic nodules. *Fluctuations in fever curves to this extent are not uncommon at this stage of disease. Distinction between spontaneous fever and a possible pyrogenic effect of streptomycin on the twenty-fourth day could not be made.*

Therapy.—Streptomycin administration was started *on the twenty-third* day of disease, *20,000 units being given every* three hours intramuscularly for four days, a total of 640,000 units.

Course During and After Therapy.—Little change was noted during the first day other than loss of pain in the primary lesion. During the second day *appetite returned, and the patient* ate with relish for the first time since the onset of illness. The exanthem disappeared. The dermal nodules became smaller and less tender, and the overlying skin was bluish. *By the* third day he was hungry and ate well. *Headache, lethargy* and depression disappeared. The *nodules continued to recede.* A day later he was totally asymptomatic, *felt vigorous* and said he could go to work. He was discharged the next day, *feeling competent to work,* with barely palpable dermal nodules without coloration and a small epithelizing ulcer.

On the eighty-eighth day after discharge he returned with a large *right* subpectoral abscess. Incision yielded about 500 cc. of thick, odorless, greenish gray pus. Cultures and animal inoculations were unproductive.

This patient had weathered *the* severe initial phase before treatment was administered. The only valid objective evidence of therapeutic effect was the rapid recession of *the* lymphangitic nodules. His subjective improvement progressed more rapidly than is usual at this stage of disease, and we believe his convalescence was accelerated.

Case 3.—*History.*—*C.* S., a woman aged 53, was exposed on Dec. 15, *1944.* Onset occurred on December 18 with chills, fever, generalized aching, headache, nausea, vomiting, pain in the right elbow and in the *right axilla* and painful papular sores on the right second and *right fifth digits.*

The patient was admitted *on the second* day of disease with a temperature of 103.3 *F.,* which rose and varied between 104.9 *and 105.1 F.* for several hours; she was delirious, disoriented and in peripheral shock, with *many blood pressure* readings at or *below* a *systolic* of *80* mm. and a *diastolic of* 55 mm. of mercury. *After slow recovery of pressures toward normal, nausea and vomiting persisted,* and she continued *to be profoundly weak and highly febrile, and she lapsed frequently* into a semidelirious state until treatment was instituted. *Additional significant physical findings of this* short, slightly obese woman were exquisitely painful areas in the right axilla and the inner right elbow that prevented palpation of buboes, a 4 mm. paronychial papule on the right second digit and a smaller one on the dorsal surface of the middle phalanx of the right fifth digit (fig. 3). Pneumonia was not present. X-ray examination of the lung showed only increased bronchial shadows.

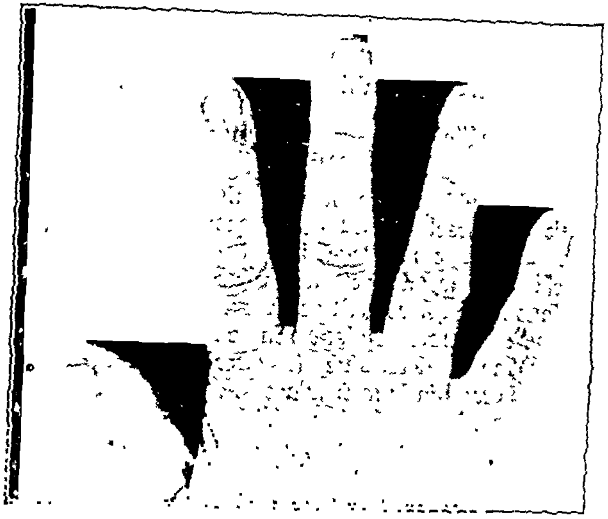

Fig. 3 (case 3).—Appearance of the primary lesions on the twelfth day *of disease,* one day *before the scabs fell off leaving almost* no residual traces of injury. The site of the small incision into the *papule* on the index finger, that healed by primary intention, is visible. Although a *relatively trivial event in recovery,* the healing of *primary lesions without* ulceration is significant of the efficacy and mode of action of streptomycin.

The results of serum agglutination tests are shown in figure 4. *With the hope of demonstrating a bacteremia,* 1.6 cc. *of her blood was spread on the surfaces* of nine blood glucose cystine agar *plates and several slants,* and *0.75* cc. was injected *intraperitoneally into each of 2 mice,* but all mediums remained *sterile and both mice survived.*

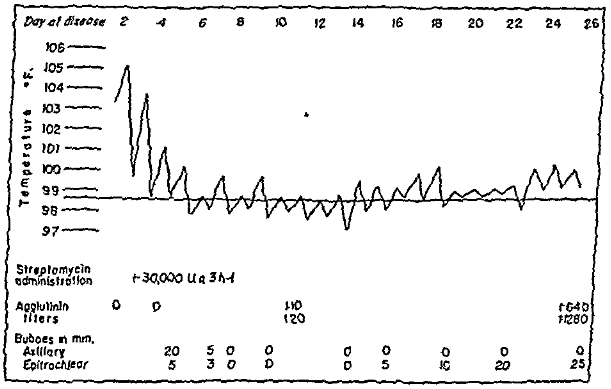

Fig. 4 (case 3).—*Dramatic fall in temperature and recession of buboes in a desperately ill patient treated on the third day of disease* Reenlargement *of a node* and *recurrence of low fever may indicate inadequate* dosage.

Therapy.—Streptomycin treatment was instituted on the third day of disease, 30,000 units being given intramuscularly every three hours for a period of five days, a total of 1.2 million units.

Course During and After Therapy.—After sixteen hours she was mentally clear, the temperature had fallen more than 2 degrees, the severe malaise was considerably ameliorated, and there was less pain in the axilla and at the elbow but the nodes were still not palpable. By the second day the temperature had fallen to a maximum of 100.1 F. Regional pain was so slight that buboes were readily palpable. A node measuring 2 by 1.5 cm. was felt in the right axilla, and one about 4 mm. in diameter was found at the right epitrochlear region. Neither papule showed an increase in size, and neither appeared to be ulcerating. The patient was afebrile throughout the third day of treatment. Nausea and vomiting had disappeared; headache and bodily aches and pains were minimal. On the fourth day the primary lesions measured 3 by 2 mm. and 2 by 1 mm. respectively and showed evidence of healing at the peripheries without ulceration of the centers. The axillary bubo measured only 0.5 cm., and the epitrochlear node was impalpable. The patient asked for more food and stated that she had no complaints except profound fatigue. On the following day the axillary node was impalpable. There was no fever, and subjective improvement continued. Treatment was discontinued. She was up in a chair on the fourteenth day of disease, with strength and vigor returning rapidly, and with no sweating during the previous four nights. Both papules had healed without ulceration.

Plans to leave on the seventeenth day were postponed because of the recurrence of low fever, pain at the right elbow and reenlargement of the epitrochlear node. During the next nine days it continued to enlarge. The overlying skin was red, and the node was tender and slightly painful, but suppuration did not occur. After discharge on the twenty-sixth day of disease there was persistence of low fever until the thirty-seventh day. Since then she has remained afebrile, and the bubo gradually receded. Examination on the forty-ninth day showed a painless, nontender node, normal in size and consistency, in a patient who had completely recovered her health and weight loss. She resumed work two days later.

The dramatic fall in temperature, prompt amelioration of severe general symptoms with rapid recession of buboes and failure of primary lesions to ulcerate even though one had been incised are attributable only to streptomycin therapy. Permanent changes of these kinds do not occur spontaneously during the severe initial phase. The fall in temperature might have coincided with a spontaneous febrile remission, which often occurs at this time, but the failure of fever to rise subsequently to or near the initial level clearly removes it from this category. Fever was present for thirty-two days, but except for the first five days it was never above 100.2 F. The axillary bubo was palpable for eight days, the epitrochlear for 1.6 months. There were fourteen bedridden days, and a disability period of 1.7 months. Obese persons at this age, with severe initial symptoms including delirium and disorientation, are notably poor risks with bad prognoses. So far as we know there is no record of a primary lesion that failed to ulcerate in a surviving patient except for rare instances among heavily vaccinated laboratory workers.

CASE 4.—*History.*—L. G., a woman aged 36, diabetic for several years, was exposed on Nov. 23, 1944. Onset occurred on November 27 with fever, chills, cough, sore throat, weakness, sweats, bodily aches and pains, headache, sore on the tip of the right fourth digit and pain in the right axilla. The temperature ranged from 102 to 103 F. She became dyspneic and profoundly prostrated and was admitted on the sixth day of disease for better control of the infection and the diabetes.

The patient was well developed, pale, febrile, severely ill and dyspneic, with extensive herpes labialis. Fine rales were audible over both lung bases. There was an indolent ulcer on the right fourth digit about 5 mm. in diameter, visible and palpable lymphangitis of the forearm, and a tender, painful axillary bubo. Lung x-rays showed "exaggerated markings to both bases, indicating bronchial infection" but no pneumonia. The blood sugar was 237 mg. per hundred cubic centimeters.

The nature of the infection was not suspected at first. After sulfadiazine administration, 2 Gm. at once and 1 Gm. every four hours for four days, she was not improved, and the temperature was 1 degree higher. It continued to rise to 102 to 104 F. daily. The probability of tularemic infection was suggested on the fourteenth day of disease.

Therapy.—Streptomycin administration was started on the seventeenth day of disease, 30,000 units being given intramuscularly every three hours for five days, a total of 1.2 million units.

Course During and After Therapy.—Little improvement was noted during the first day, but the patient stated that she felt better. By the second day subjective and objective favorable changes were prominent. Headache and mental dulness had disappeared; she felt better, stronger, less prostrated and cheerful. Cough had disappeared, and the throat was less sore. Within two days the bubo had diminished from 3.5 by 2 cm. to 2.5 by 1.5 cm., and the primary lesion had become painless. She was afebrile throughout the third day of treatment and announced that she felt "perfectly well." Improvement continued during the fourth day, associated with beginning epithelization of the ulcer. She continued to gain in weight and vigor and it was difficult to keep her hospitalized. The bubo receded gradually. Fever disappeared on the forty-second day of disease. During the next six weeks the bubo receded to a diameter of about 5 mm., at which size it still remains, painless and not tender.

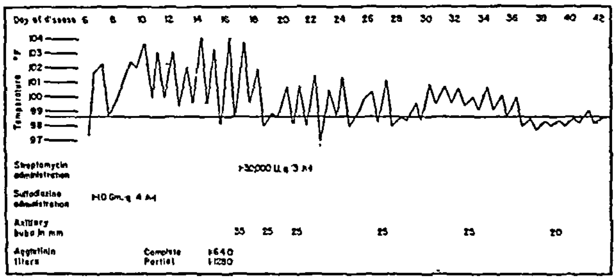

Fig. 5 (case 4).—After the twenty-second day of disease temperature elevations occurred for only three to five hours during each night. The patient was unaware of fever and was eager to go home. The curve also shows comparative effects of sulfadiazine and streptomycin.

Although the rapid transition from a state of illness to one of relative comfort within three days could scarcely have been a spontaneous change at this stage of disease in a patient with a bubo of this size, the concomitant effect on the temperature was less permanent. The maximal-minimal temperature readings shown in figure 4 do not reflect the progressive clinical improvement that occurred. The hospital chart showed that the temperature elevations that averaged about 101 F. for two weeks after treatment was given occurred chiefly during the nights, and for only three to five hours. There was little or no fever during the remainder of the days. The reasons for this unusual temperature curve are not entirely clear. There were thirty-five febrile days and twenty-eight days spent in bed. Palpable adenopathy persisted for 2.8 months.

CASE 5.—*History.*—M. C., a Negro woman aged 40, could not give a reliable chronologic account of exposure or of onset of illness. It is presumed that exposure was on Dec. 13, 1944 and that onset occurred on or about December 17 with chills, fever, sweats, nausea, vomiting, anorexia, severe malaise, headache, mental dulness, a sore on the lateral aspect of the tip of the felt fourth digit and pain in the left arm and in the left axilla. She remained at home for more than two weeks and was admitted on or about the seventeenth day of disease with the complaints unchanged, with a diagnosis of felon of the finger. The significant findings were temperature of 102.1 F., a ragged, necrotic ulcerated lesion on the terminal phalanx of the ring finger, a painful, tender, left axillary bubo that measured 5.5 by 4.5 cm., and normal lungs both by physical signs and by x-ray.

Therapy.—On the twentieth day of disease streptomycin administration was started, 30,000 units being given intramuscularly every three hours for five days, then 15,000 units intramuscularly every four hours for two days, a total of 1.38 million units.

Course During and After Therapy.—By the end of the first day the bubo had diminished to 4 by 3 cm. It was less painful and less tender. There was a decided amelioration of all symptoms. Before the end of the second day she was afebrile and remained so thereafter. Chills and sweats ceased abruptly, not to return. Disappearance of all general symptoms occurred before treatment was discontinued. By the fourth day the axillary bubo was resolvable into two discrete nodes. The smaller one receded rapidly to a 6 mm. diameter within a week; the larger was still 2 by 2 cm. when she left the hospital on the thirtieth day of disease. The latter node remained stationary for three weeks; then it enlarged, liquefied rapidly and ruptured spontaneously. The sinus tract healed in two weeks.

The change from a state of wretchedness to one of almost complete comfort was dramatically short, with abrupt and permanent disappearance of fever. Many patients have fever of the same or shorter duration, but commonly it does not disappear so abruptly, and especially in the presence of a liquefying bubo. There were twenty-two febrile days, twenty-six days in bed. The duration of adenopathy was 2.2 months.

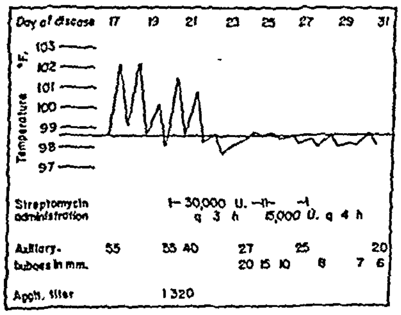

Fig. 6 (case 5).—Note the abrupt termination of fever before the end of the second day of therapy. Although an important change, it is less significant in relation to stage of disease than the fall shown in figure 4. The additional streptomycin over the usual dosage was given with the unrealized hope that it might prevent ultimate liquefaction of the larger node.

Case 6.—*History.*—M. P., a farmer aged 60, experienced multiple exposures during November and early December 1944. Onset occurred on December 7 with a severe chill, high fever and sweat; he ached all over. Severe symptoms lasted for four days, after which they continued in milder form associated with moderate to low fever. On the third day of disease primary lesions appeared on the left fifth digit, the right thumb and the dorsum of the right hand. Painful swellings appeared simultaneously in each axilla. Until admission the clinical course was characterized by malaise, weakness, loss of weight, persistent fever, multiple ulcerations on the hands and fingers, and progressively enlarging, painful buboes. Two dermal lymphangitic nodules developed on the right forearm.

The patient was admitted on the thirty-sixth day of disease with a temperature of 101.6 F. Significant findings were evident loss of weight, moderate secondary anemia, a painful swelling in the left axilla measuring 4 by 4 cm., an 8 mm. ulcer on the tip of the left fifth digit, an ulcerated paronychial lesion on the right thumb, a 14 mm. ulcer on the dorsum of the right hand and two regressing lymphangitic nodules on the dorsum of the right forearm, each about 3 mm. in diameter.

At the time streptomycin was instituted, the left axillary bubo was a warm, tender, painful mass at least 5 by 6 cm. in diameter, apparently composed of two nodes, each fluctuant and almost completely liquefied.

Serum obtained on the thirty-eighth day of disease agglutinated both Bacterium tularense and Brucella abortus completely in 1:1,280 dilution. Repetition on the sixty-first day showed both titers unchanged and a Proteus OX_{19} titer of 1:20, partial in 1:40 dilution. Hemoglobin varied between 10 and 10.5 Gm. (64 to 67 per cent Sahli), and red blood cells varied between 3.28 and 3.41 millions per cubic millimeter.

Therapy.—On the day after admission and for three days thereafter the patient received by vein 7.5 cc. of commercially prepared antitularense horse serum, a total of 30 cc. in ninety-six hours.

Streptomycin therapy was instituted on the fiftieth day of disease, 23,500 units being given intramuscularly every three hours for five days, a total of 940,000 units.

On the following day incision of the axillary abscess yielded about 40 cc. of pus. Six days later an incision was made to evacuate another abscess deeper in the axilla.

Course During and After Therapy.—During the ten days subsequent to serum administration, no significant subjective or objective changes were noted. By the end of the first day of streptomycin therapy there was slight but definite amelioration of all subjective symptoms but no other changes of note. After evacuation of the axillary abscesses there was rapid, progressive improvement that continued uneventfully to complete recovery. The uninformative temperature chart is omitted.

Since the chief cause of persisting illness was the suppurative adenitis, it is probable that incision and drainage of abscesses contributed most toward the recovery, even though definite subjective improvement had occurred before the first incision was made. Here again, as in case 2, little could be expected beyond an acceleration of convalescence, but it seemed that that little was achieved.

Case 7.—*History.*—J. M., a woman aged 26, was exposed on Nov. 24, 1944. Onset occurred on November 29 with chills, fever, sweats, cough, severe malaise and a painful sore beneath the edge of the nail of the left third digit. Small tender buboes appeared in the left epitrochlear and axillary regions on the second day. Symptoms and signs of pleurisy over the right lower lobe developed on the seventh day followed by clinical and x-ray evidences of a progressively developing pneumonia in that lobe. By the fourteenth day the lobe was consolidated. Remittent fever continued to reach daily levels of 103 F. The buboes measured 2 cm. and 2 by 3 cm.

Serum taken on the twelfth day agglutinated Bact. tularense in 1:80 dilution. Two weeks later the titer was complete in 1:1,280 dilution. An intradermal test with bacterial antigen gave a positive reaction on the eighteenth day.

Course After Treatment with Hyperimmune Goat Serum.—On the eighteenth day of disease she received by vein 60 cc. of hyperimmune goat antitularense serum prepared by inoculating animals with living virulent organisms. During the subsequent week the temperature fell gradually to normal. Early convalescence, though slow, progressed satisfactorily. Buboes were impalpable after the twenty-second day. Nineteen days after serum administration an x-ray showed resolution of the pneumonic area and she was permitted to go home. The summary at this stage showed that there had been twenty-five febrile days and twenty-eight days spent in bed, and an apparent duration of disease of 1.4 months.

After returning home the patient felt well except for severe headache. Continuation of low grade fever was soon noted. During the next month she experienced several distinct bouts of higher fever associated with general malaise, anorexia and loss of weight. On February 14, the seventy-eighth day after onset, continuous fever recurred, varying between 102 and 103 F. Two days later there was pain in the upper left abdominal quadrant and soon thereafter her abdomen began to swell. This continued for two weeks, at which time she was again hospitalized.

Examination showed that the patient was somewhat emaciated and dehydrated. She complained of generalized abdominal distention and pain in the upper left quadrant. A friction rub was heard over the splenic area on deep inspiration. The abdominal girth was commensurate with that of a full term pregnancy, and the cavity was obviously distended with fluid. The thorax was negative to physical examination and the lungs were clear by x-ray. Temperature maxima varied daily between 102 and 104 F.

An agglutination test showed a titer of 1:320. On repetition the titer rose gradually and became stabilized at 1:1,280. Abdominal paracentesis yielded a thick, cloudy, straw colored fluid which failed to initiate growth after cultivation in several mediums. A sample injected intraperitoneally into a guinea pig caused its death about a week later. Sections of its liver, spleen and lungs revealed numerous focal necroses which Dr. Paul Kimmelstiel considered were compatible with the lesions of rodent tularemia.

Streptomycin Therapy.—On the one hundred and third day of disease streptomycin therapy was instituted. The dosage was 50,000 units intramuscularly every three hours for the first two days, followed by 30,000 units every three hours for the four succeeding days, a total of 1.76 million units.

Course During and After Streptomycin Administration.—After the fourth injection the patient was intensely nauseated, vomited and became extremely drowsy. Nausea and vomiting continued, and somnolence became so extreme that she could scarcely be aroused to take fluids or food. The temperature was in the 100 to 102 F. range, and the abdominal fluid level was lower. In the absence of any other signs of possible drug toxicity, treatment was continued without interruption. Nausea, drowsiness and a widely fluctuating temperature continued until the fourth day. Then the temperature began to fall, nausea became less, and the splenic friction rub, which had been heard rather consistently, disappeared not to return. The temperature reached normal on the sixth day and, except for one rise on the eighth day, remained normal thereafter.

Some fluid was still present in the abdominal cavity at the time the temperature reached the normal level. Another sample was obtained and inoculated intraperitoneally into a guinea pig. This animal survived.

Subsequent to the one hundred and tenth day of disease, the eighth day after onest of therapy, the patient was afebrile. She was hospitalized for an additional two weeks, during which her appetite returned, the lost weight was regained and the abdomen became perfectly flat without evidence of fluid. When seen three weeks later she appeared to be in perfect health and had resumed her customary activities.

This patient presented several unusual features. Subsequent to a fairly satisfactory recovery induced by hyperimmune serum therapy there occurred a relapse of serious proportions despite the fact that the most serious early lesion, the pneumonia, had resolved completely. Bactericidal properties have not been demonstrated for tularemia immune serums. Since the beneficial results of serum therapy are apparently due to a bacteriostatic effect, the patient probably experienced a sequence of events somewhat as follows: It is clear that the small lesions established early in the accessible lymph nodes, and the extensive lesion in the lung, were prevented from progressing by bacteriostatic action long enough to permit resolution by the usual processes of repair. Bacteria in some of the lesions established early in the spleen escaped the intensity or duration of bacteriostasis necessary to permit completion of a similar process, and with gradual release from inadequate local bacteriostasis there occurred progressively splenitis, perisplenitis, and peritonitis with infected exudate.

Since the duration of disease in all cases of tularemic peritonitis known to us has been long, ranging from ten months up to two and one-half years as reported for the case recorded by Kilbury and Fulmer,[2] in which distention due to peritoneal exudate persisted for more than three months, the rapid restoration of this patient to a completely normal state was a highly significant change. The temperature chart is unfortunately not available.

The dramatic, favorable response to streptomycin therapy was marred only by the appearance of intense nausea, vomiting and deep somnolence. Since these symptoms are frequently caused by the disease, somnolence a constant feature of its terminal phase when the density of bacteremia is demonstrably high, we regard them not as an expression of toxicity of the antibiotic but as manifestations of an acute intoxication caused by rapid absorption of bacterial products through a highly absorptive serous membrane consequent on rapid killing of numerous bacteria within a short time.

COMMENT

It is noteworthy that each of the first 6 patients experienced relief from the distressing general symptoms of headache, mental dulness, sense of prostration, arthralgias, myalgias, chills or chilly sensations and nausea before the end of the first day of therapy. This effect was a striking feature by the end of the second day, and it appeared even with very low, possibly suboptimal dosage. We infer that bacteriostasis, which must undoubtedly have occurred within the first twelve hours of therapy, is associated with failure of the bacteria to elaborate the diffusible substances that lead to the production of these symptoms. Failure of papular primary lesions to ulcerate, even after incision, seems also a result either of bacteriostasis or a regional bactericidal effect.

Streptomycin Dosage.—It is doubtless partly fortuitous that our trial dosage proved to be so effective. By hindsight we regard it as a minimal effective dosage in relation to the severity and duration of disease encountered. It is probable that we gave too little streptomycin, or for too short a period, to obtain the best possible results in several cases. We probably erred on both counts in relation to case 2, in which a doubtfully palpable lymph node was situated deep in the pectoral fold. The subpectoral abscess was caused by extension from this suppurating node, and it is possible that had more streptomycin been given over a longer period liquefaction might have been prevented. The same criticism might apply to the reenlargement of the epitrochlear node in case 3 and to the persistence of fever and the bubo in case 4. Although neither bubo suppurated, convalescence might have been materially shortened had our dosage been, for example, 50 or 60 thousand units every three hours for the first four days, followed by 30 to 50 thousand units every three hours for two or three additional days.

It is probable that administration by continuous subcutaneous drip, which seems to be tolerated better than a continuous intravenous drip, would have been more effective than intermittent intramuscular administration in securing high initial blood and tissue concentrations, the most important factors for successful therapy with all bacteriostatic and bactericidal agents.

We were unable to treat a patient with tularemic pneumonia, the commonest serious visceral lesion. We would expect a dosage of about ½ million units daily by continuous subcutaneous drip to induce extremely favorable results. If clinical evidences of septicemia were present—nonremittent high fever, continuous delirium and enlarging liver or spleen—the dosage must be larger, possibly not less than 2 to 4 million units per day. In view of the numerous bacteria within such patients, and with the experience of patient 7 in mind, we think that those who may guide the management of septicemic patients should anticipate symptoms of profound intoxication and be prepared to cope with them.

We were unable to determine streptomycin concentrations in blood or serum at the time these patients were treated. From later studies we infer that administration of 30,000 units every three hours maintained concentrations between 2 and 4 units per cubic centimeter of serum during the period of administration.

[2] Kilbury, M. J., and Fulmer, S. C.: Tularemic Peritonitis: Report of Case Observed for Four Years, South. M. J. 24:856 (Oct.) 1931.

Relapse.—The frequency of relapse in tularemia is unknown. From available information we estimate it to be about 1 in each 700 to 800 cases. In this connection it is noted that the relapse following serum therapy in the seventh patient was the first to occur among 900 patients so treated. None occurred in the streptomycin treated patients up to eleven months after recoveries.

Comparison with Serum Therapy.—Comparative estimates of the effects of these two therapeutic agents were unavoidable. With due regard for the small size of the streptomycin series, one feature was outstanding: the uniformity of the clinical responses in character, degree, continuity and time of appearance. Although we have records of serum treated patients that compare favorably with any recorded here, we could not match them by selecting any seven case records at random. The responses to serum therapy have always shown a wide range of variability in character, degree, continuity of effect and time of appearance. This has been attributed chiefly to variability in the efficiency of individual defense mechanisms as they were aided by a bacteriostatic agent. The administration of a bactericidal agent that acts directly on bacteria and independently of the variable, individual defense mechanism possibly accounts for the observed uniformity of responses to streptomycin.

Effect of Therapy on Residual Immunity.—Recovery from tularemia confers an unusual degree of protection against external reinfection, often of lifelong duration. This resistance is associated with persistence of serum agglutinins, a fact which in itself implies continuous antibody formation. Although final proof by recovery of the causative agent is still lacking, many surmise that both the lasting protection and the persisting serum antibodies are caused by retention of living bacteria within the recovered patient, held in innocuous bacteriostatic equilibrium. The late recrudescences that occasionally occur, often subsequent to unusual physical effort or exposure but sometimes without traceable antecedent change, are attributable to disturbance of this equilibrium with consequent release of the long retained bacteria from bacteriostatic control. Effective treatment with either arsenicals or penicillin during the early primary stage of syphilis kills all treponemes and leaves patients susceptible thereafter to external reinfection. Must we anticipate a similar situation after early streptomycin therapy of tularemia? There is clinical evidence that treponemes are disseminated relatively slowly from the site of the primary lesion, whereas Bact. tularense spreads to regional lymph nodes very rapidly, apparently even during the incubation period. Hence before streptomycin therapy could be initiated, even if on the first day of disease, the probability is great that dissemination had occurred and that areas of potential antigenic stimulus were already established. Only in the event of a laboratory infection in which suppressive or prophylactic streptomycin therapy could be started immediately after infection would the therapy be apt to prevent antibody formation and to leave the patient susceptible to reinfection.

Maximal and Residual Titers

The maximal complete agglutination serum titers observed during the acute phase of disease compared with those obtained eight months later are shown in relation to the days of disease on which streptomycin therapy was instituted.

Day of Disease on Which Streptomycin Therapy Was Instituted	Maximal Titer During Acute Phase	Residual Titer Eight Months After Onset of Disease
3	1:640	1:1,280
8	1:2,560	1:1,280
17	1:640	1:640

If persisting serum agglutinins are an index of maintained resistance they should indicate the immune status of patients who were treated with streptomycin. During the eighth month after onset serum was obtained from the 3 patients who received streptomycin therapy earliest in the course of disease. The highest serum dilutions that showed complete agglutination were compared with the same titers obtained during the acute phases. On the basis of this evidence there seems little likelihood that early streptomycin therapy has jeopardized the immune status of any of these patients.

DICUMAROL IN ACUTE CORONARY THROMBOSIS

H. RAYMOND PETERS, M.D.; J. ROY GUYTHER, M.D.
and
CHARLES E. BRAMBEL, Ph.D.
Baltimore

The increasing incidence of coronary thrombosis has been dwelt on frequently in recent medical literature and indeed has at times reached the lay press. The ever present challenge of this disease to the medical therapist might best be brought home to the physician himself when he realizes that approximately one out of five members of his own profession is stricken fatally with coronary thrombosis and occlusion. Thus, recent statistics show that in 1944 this disease accounted for 18 per cent of the deaths of physicians in this country.[1]

Much has been written on the pathogenesis, diagnosis and therapy of coronary thrombosis. Certainly in more recent years the clinician has had a better knowledge of the pathogenesis. His alertness and ability today to make earlier diagnosis has automatically given more effective treatment. Treatment itself is unfortunately limited by lack of specific therapy. The patient is put to bed, strenuous efforts are made to relieve the pain and otherwise therapy is more or less symptomatic. In addition, constant and careful watch is kept for complications. Under such a regimen approximately 80 per cent of those suffering the first attack now recover. In the remaining 20 per cent sudden death may occur without warning either as a result of ventricular fibrillation, from rupture of the softened area of the ventricle or from complete heart block. However, the greater number of cases with fatal termination are from congestive failure and embolism.

Master, Dack and Jaffe [2] noted that congestive failure caused 33 per cent of the deaths among 500 cases of coronary thrombosis and it was associated with severe shock in 16.5 per cent of additional fatal cases. Hence death in one half of the cases was due to cardiac decompensation with or without shock. In reviewing the subject of embolic phenomena Blumer [3] states that 50 per

cent of cases of myocardial infarction are accompanied by mural thrombi within the ventricles, and in approximately 14 per cent of cases clinical evidence of embolism is observed from this source. Levine [4] too has recently emphasized the importance of mural thrombi and subsequent arterial emboli. Master and his associates [2] stated that in patients under 50 the most common cause of death was arterial embolism. Falk [5] emphasized the fact that massive pulmonary embolism is responsible for a significant percentage of deaths following acute coronary occlusion but that the sources of the emboli are the veins of the pelvis or lower extremities. Such massive pulmonary embolism accounted for 6 of 60 deaths occurring in a series of 128 cases of acute coronary occlusion reported by Woods and Barnes [6] in 1941. Nay and Barnes [7] undertook the study of 100 consecutive cases of acute myocardial infarction encountered at the Mayo Clinic to establish the incidence of vascular complications during the immediate convalescent period. They found embolic or thrombotic complications in 37 of the 100 patients. In fact these complications were important contributing factors to the death of 12 patients. The vascular complications were subsequent myocardial infarction in 15, pulmonary embolism in 14, cerebral embolism or thrombosis in 8, thrombophlebitis in 7 and arterial occlusion in 4. There was a total of 48 complications in 37 patients.

In the face of such pertinent statistics regarding the frequency of thrombotic and embolic processes following coronary thrombosis the question of therapeutic prophylaxis arose. It became our purpose then to observe the effect of an anticoagulant with regard to reducing the incidence of such complications.

MATERIAL

We have critically reviewed all the cases of coronary occlusion with infarction seen in the medical services of Mercy Hospital in Baltimore during the past three years. No case is included in this paper which did not have a typical clinical history substantiated by laboratory findings and electrocardiographic tracings. Thus a few patients who probably had myocardial infarction but who died within the first few hours were excluded because they did not have adequate laboratory work or electrocardiograms to substantiate fully the clinical impression of coronary occlusion. We found 110 cases which fulfilled the necessary criteria. All received the generally accepted treatment for coronary thrombosis. Sixty patients had not received dicumarol and are used as the control group. In March 1943, for purposes of comparison, we began to administer dicumarol to a series of patients. This series has now reached a total of 50. The age and sex distribution in these two series closely approximate each other and afford a fair basis for comparison (table 2). In our control group of 60 patients the incidence of cardiac decompensation of at least moderate degree (grade 2, 3 or 4) was found to be 33 per cent. The incidence of clinical embolism in the same control series was 16 per cent. These figures for such complications are in accord with those of other investigators.[8]

RATIONALE

Since 1943 we have determined prothrombin clotting times on most of the patients who had coronary occlusion. The determinations have been done by the method of Quick,[9] using a modified thromboplastic reagent as described by Brambel.[10] Other types of thromboplastins did not yield the desired sensitivity or reproducibility. The importance of using standardized reagents has been recently emphasized.[11] Determinations were made in each instance on undiluted plasma and on 12.5 per cent plasma. Several investigators [12] have shown that slight variations of prothrombin activity can be better detected with diluted plasma. Normals had previously been established for whole plasma of 12 to 14 seconds and for diluted (12.5 per cent) plasma, 85 to 100 seconds. It was noted that 3 of every 4 cases of coronary thrombosis exhibited an increased prothrombin activity, i. e. increased clotting tendency. There were 21 patients with coronary thrombosis whose prothrombin times were within normal range or above normal. Cephalin-cholesterol flocculation tests were made in 13 of the 21 cases and 10 were positive, suggesting hepatic damage. Since there is considerable evidence to indicate that plasma prothrombin concentration is intimately related to the liver and its normal function, and where there is hepatic damage the plasma prothrombin concentration is lowered, one would expect to find increased

prothrombin clotting times in these cases.[13] In the early phase of this study the need for repeated checks of plasma prothrombin time on patients with initial normal values (hepatic damage?) was not realized. We now know that such patients can later show decreased prothrombin times. In fact, in 2 nondicumarolized patients of this type embolic processes did occur. Additional evidence in favor of the fact that patients with coronary thrombosis have a disturbance in their coagulation system and tendency toward clotting is obtained from the work of de Takats,[14] who showed that these patients exhibited increased resistance to the action of heparin.

Of the 67 cases showing accelerated prothrombin clotting times, results on whole plasma varied from 11 to 14 seconds and on diluted (12.5 per cent) plasma from 47 to 75 seconds It is our opinion that the increased clotting tendency is *attendant with the vascular occlusion* rather than the cause of it, because at times it does not make its appearance until the second or third day. Nevertheless the equilibrium of the coagulation elements of the blood has shifted to a state favorable to clotting, and this condition favors extension of the thrombus and *the formation of mural thrombi within the ventricles of the heart*.

Having repeatedly observed an increased clotting tendency to be present in coronary thrombosis, and aware of the frequency and danger of emboli, it occurred to us that the use of an anticoagulant might be efficacious in the prevention of such complications in patients suffering from coronary vascular occlusion. During the last year Levine [1] has suggested a similar approach to the problem. He states that he has used anticoagulants in an effort to prevent formation of thrombi but that "the experience is too limited to permit any final conclusions." Working with animals, Solandt and Best [15] in 1938 furnished evidence that anticoagulants may be of benefit in experimental coronary thrombosis. These investigators found that they could gradually occlude a coronary artery by thrombus formation and that this thrombus and the resulting cardiac infarction may be prevented by administration of adequate amounts of an anticoagulant (heparin). Dale and Jacques,[16] also working with animals, showed that dicumarol hindered and, in a fair percentage of cases, prevented the formation of extravascular and intravascular thrombi. Its effectiveness paralleled the reduction in plasma prothrombin activity.

TABLE 3.—*Dicumarolized versus Nondicumarolized Patients*

	Dicumarolized		Nondicumarolized	
	Number	Per Cent	Number	Per Cent
Number of patients......	50	....	60	....
Deaths	2	4	13	20
Clinical embolism .. .	1	2	10	16 6
Number of patients given digitalis	8	....	17	. ..
Deaths of patients who were digitalized	1	12 5	9	53

Premonitory symptoms of coronary occlusion certainly are not often recognizable, and hence the initial process cannot be prevented. However, administration of adequate amounts of an anticoagulant may prevent extension of the thrombus and reduces chances of future formation of mural thrombi or venous thromboses in the lower portion of the body. For economical reasons and because of the ease of administration, dicumarol was selected as the anticoagulant of choice. While heparin institutes immediate effect, its administration raises practical difficulties. Moreover, *vascular complications in our experience and in the reports of others* [17] *seldom* occur before the fourth day. It seems that dicumarolization can be established *before this danger period* is present.

Accordingly, considering the mode of administration safe *and to evaluate its action, dicumarol was administered to 50 patients with coronary occlusion*. The ones selected were those in whom there was a definite clotting *tendency judged by prothrombin time determination* of diluted plasma. No other criteria were used in selecting the patients. *In most instances the drug was started immediately after the initial prothrombin determination*, and the effort was made to maintain the patient's *prothrombin activity between 35 and 50 per cent of normal*. The drug was continued during the hospital course, which *in the average case was at least forty-two days. This carries the patient* well beyond the period of greatest danger as regards embolic phenomena.[17] *The patients treated received an average of 3,400 mg* of dicumarol during the course of administration.

TOXIC EFFECTS

During the two and one half *year period in which we* have administered dicumarol to *patients with coronary* occlusion *we have observed* very few toxic effects of the drug. The only immediate side effects have been a mild diarrhea, which is easily controlled, and occasional nausea or headache. Hypoprothrombinemia and consequent hemorrhage, should it occur, can be *controlled by the intravenous injection of* 37.5 mg. of *menadione bisulfite*.[18] This corresponds to Hykinone *72 mg* Contrary to the reports of a fairly substantial percentage *of hemorrhagic incidents in some* clinics,[19] we have been *more fortunate* in this respect. *Of the* 50 patients to whom *dicumarol was administered*, microscopic hematuria *was noted in 3*. No cases of frank hemorrhage *and no deaths ascribable to* dicumarol occurred in this series.

Several investigators [20] have shown that dicumarol does not disturb the *formed* elements of the blood, *nor does it affect the capillary fragility and clot retraction*. The blood coagulation *time is altered only after* prothrombin *activity is reduced beyond* 50 per cent of normal. *Unfortunately, the erythrocyte sedimentation* rate is increased by the drug to such an extent that it *no longer serves as an index of healing of the damaged myocardium*. However, *in our opinion this disadvantage is outweighed if sufficient benefit from anticoagulant therapy can be demonstrated. Dependence on the*

sedimentation rate as a guide for allowing coronary patients out of bed has already been somewhat altered by the recent trend [21] to make ambulant all cardiac, including coronary, cases sooner than was once deemed wise.

With regard to so-called delayed toxic reactions, we can report that none have been noted. We have carried several patients on this anticoagulant continuously for over a year without noting any ill effects. One patient has been given the drug regularly for a period of two years with the idea in mind that a recurrence of thrombosis might be prevented. Putnam [22] in New York has carried cases of multiple sclerosis on regular doses of dicumarol over a period of three years.

DOSAGE

We have in our clinic no standard dosage scale. Following the initial prothrombin time determination, the first dose is usually 300 mg. The subsequent dose is estimated by the patient's response to the previous dose. In this manner hyperreactors can be detected before the cumulative effect of several doses is manifest. Determinations have been deemed necessary only every other day because the maximum effect of any given dosage is obtained thirty-six to forty-eight hours after it is given. The prothrombin clotting time of diluted plasma (12.5 per cent) is a more sensitive indicator of changes taking place as the clotting mechanism is altered by the drug. Should the clotting time for 12.5 per cent plasma reach 400 seconds, this is interpreted as a caution signal and future doses are governed accordingly. In a number of selected cases, after it has been satisfactorily demonstrated that the patient is not a hyperreactor and his response can be fairly well predicted, the patient has been continued on dicumarol after discharge from the hospital, returning to the clinic twice a week for prothrombin determinations and succeeding doses. This procedure is not generally recommended and, indeed, is not without hazard, unless complete cooperation of the patient, his physician and the laboratory is secured.

No patient should be given dicumarol unless adequate laboratory facilities are available to check the prothrombin clotting time with appropriately standardized reagents. Experience and good judgment are essential in estimating dosage on basis of response of the coagulation system to the drug.

CONTRAINDICATIONS

No patients should be given dicumarol who have renal disease, evident hepatic disease or a blood dyscrasia with hemorrhagic tendencies. Patients with definite hypertension must be carefully evaluated, and special care taken with dosage. Due attention must be given to the fact that salicylates [23] and quinine [24] exert a dicumarol-like effect on prothrombin activity. A decrease in plasma prothrombin level has been observed in some patients receiving sulfonamides.[25] Although this may be interpreted as a manifestation of toxicity of the sulfonamide and is not to be expected in every patient, it is well worth noting. If it becomes necessary to administer one of these preparations concomitantly with dicumarol, special caution is advised to assure control over the cumulative action.

RESULTS

Of the 60 patients treated in the routine manner for coronary occlusion and not receiving dicumarol, 13 died. Six of these 13 died from clinical embolism, 5 from cardiac decompensation and 2 from sudden unexplained cause, probably ventricular fibrillation. In the group of 50 patients who were given dicumarol, 2 died. One of these had received only two doses of the drug totaling 300 mg. This patient died on the fourth hospital day from renal complications. The last blood urea determination was 138 mg. per hundred cubic centimeters. In the light of present day knowledge this patient would not be considered a candidate for dicumarol therapy because of evident renal dysfunction. The second died of myocardial failure, during an attack of paroxysmal ventricular tachycardia on the seventeenth hospital day.

In the group of patients who were not given dicumarol there were 10 with clinical embolism. There was 1 case of peripheral arterial occlusion: the remainder were pulmonary or cerebral. Six of the 10 cases terminated fatally. The incidence here was 16 per cent, which corresponds fairly closely with the incidence of 14 per cent reported by Blumer.[3] Of the 50 patients receiving dicumarol, only 1 had any clinical evidence of embolism. It is to be noted that in this case the administration of dicumarol was unduly delayed until the eighth hospital day and dicumarolization had not been established when a presumptive cerebral embolism took place. This particular patient, a white man aged 56, entered the hospital four hours after the onset of substernal pain which later was demonstrated to be due to a posterior myocardial infarction. The prothrombin clotting time on the day of admission was found to be 15 seconds for undiluted and 80 seconds for diluted (12.5 per cent) plasma. Unfortunately, the determination was not made again for the next seven days. We have frequently observed a normal value on the day of the attack but find the very next day that the prothrombin clotting time of diluted plasma is decreased. On the patient's eighth day in the hospital a determination gave the value of 14 seconds on undiluted and 67 seconds on diluted (12.5 per cent) plasma. Three hundred mg. of dicumarol was given that afternoon. Twenty-four hours later the patient had twitching of the left hand followed by weakness of the extremity. The next morning value for undiluted plasma was the same and for diluted (12.5 per cent) plasma was 72 seconds. Suspecting that an embolic process had occurred, we again administered 300 mg. of dicumarol. From this point on plasma clotting times showed that dicumarolization had been effected. On the tenth hospital day there was a generalized convulsion followed by a transient left hemiparesis. The blood pressure prior to the convulsion was 80 systolic and 58 diastolic. After this second episode the patient had an uneventful course. He later became ambulatory and left the hospital with little residue from the paralysis. Although the patient was undoubtedly dicumarolized at the time of the second presumptive embolic phenomenon, it would seem to us that the delay in the intital administration of the drug might well have favored the building up of a sizable intramural thrombus.

Among the 60 cases studied in which dicumarol was not given routinely and in which the incidence of embolism was significant, 1 is worthy of particular comment:

REPORT OF CASE

A white man aged 54 was admitted to one of the private services because of the complaint of a sudden sharp pain down his left arm, followed by a profuse sweat and generalized weakness. He was known to have had diabetes for some five years and was also known to have a moderate hypertension averaging 180 systolic and 100 diastolic. On admission, which was four days after the onset of pain, an electrocardiographic tracing and other laboratory data showed evidence of a posterior myocardial infarction. Shortly after admission his plasma prothrombin time was 14 seconds for undiluted and 57 seconds for 12.5 per cent plasma. No dicumarol was given and no further prothrombin clotting time determinations were obtained for five days.

The patient was quite comfortable for the first four days. On the fifth hospital day he complained of pain in his left foot. It was noted that the toes were slightly discolored and that the foot was cold. Papaverine ½ grain (0.032 Gm.) was given intravenously every four hours. The discoloration increased, however, and in several days a line of demarcation was evident just below the knee. On the fourth day after the first signs and symptoms of embolism had been noted (the ninth hospital day) dicumarol therapy was started. There was no change noted in the limb except for the presence of dry gangrene from toes to knee. On the twelfth day after occurrence of the embolism, while dicumarolization was now considered at a satisfactory and safe level with respect to prevention of further embolism, it was deemed wise to lower this level in the face of a major operation. Accordingly, early on the day of operation the patient was given 37.5 mg. of menadione bisulfite, which resulted in an increase in plasma prothrombin activity from 35 to 65 per cent in eight hours. Anesthesia was initiated with sodium pentothal and continued with ether. No undue bleeding occurred during the midthigh guillotine type amputation, and the patient withstood the procedure well. Dicumarol was continued postoperatively. The stump remained healthy and after ten weeks there have been no further complications.

COMMENT

This is a case in which an embolism of serious nature occurred nine days after the onset of a coronary occlusion. We can only speculate what course the case might have taken had dicumarol been started on admission. The ability of vitamin K derivatives to control the dicumarol level sufficiently to permit major surgery without fear of undue hemorrage is demonstrated. We have now been able to observe the effect of dicumarolization on over 1,800 miscellaneous cases in this clinic and have found the need for vitamin K therapy in comparatively few. In no case when a vitamin K derivative was given in adequate dose (Hykinone 72 mg.) was there failure to respond. This observation is in accordance with the work of others.[18]

In the group of 60 patients who did not receive dicumarol there were 17 with congestive failure who were given digitalis. Of these 17 patients 9 (53 per cent) died, most of them as a result of embolism. In the group of patients receiving dicumarol 8 were given digitalis for congestive failure; 1 of these (12.5 per cent) died. This death has already been mentioned as due to renal complications.

The danger of digitalis preparations in coronary thrombosis has recently been stressed by Askey and Neurath.[26] They reported that digitalis given to 32 patients having myocardial infarction complicated by auricular fibrillation and congestive failure proved to be more harmful than beneficial. Thirty-one of these 32 patients died, 13 of them from arterial emboli. They found that the administration of digitalis did not materially increase the incidence of sudden death from ventricular fibrillation or of rupture of the heart but did significantly increase the incidence of embolism. These authors concluded that digitalis was contraindicated in myocardial infarction. In a group of 100 patients with myocardial infarction studied by Nay and Barnes,[7] 12 were given digitalis. Two thirds of the cases were complicated by embolism. de Takats [27] and Massie and his associates [28] each have shown that digitalis preparations increased the coagulability of the blood as measured by the heparin tolerance and the clotting time. Despite the inability of certain observers [29] to duplicate this effect of digitalis in their cases, we have been able in our clinic to demonstrate repeatedly a decreased prothrombin clotting time on administration of digitalis. It is emphasized that such decrease was noted only in the more sensitive diluted plasma determination. In view of this action of digitalis and the knowledge that confinement to bed, whatever its cause, tends to favor thrombosis,[30] we find it difficult to disregard the need for the action of an anticoagulant. The results obtained in the small group of 8 patients with myocardial infarction plus congestive failure in which digitalis was used without evidence of embolism suggest that dicumarol is capable of opposing the thrombogenic property of digitalis and reducing the incidence of embolism. Consequently it is felt that when congestive failure supervenes in myocardial infarction and the patient is receiving dicumarol, digitalis may be given without fear of enhancing the possibility of thrombus formation. Other drugs widely used in the treatment of coronary vascular disease, such as theobromine and theophylline, have been shown experimentally to possess the same ability as digitalis to increase the plasma prothrombin activity.[31] Here again dicumarol administration may serve to counteract such undesirable action.

Repeated electrocardiograms were made on the 50 dicumarolized patients. We were not impressed by a quicker return toward normal in these tracings than was noted in the patients not receiving dicumarol. There have not been enough patients receiving the drug for long periods of time to suggest that the incidence of recurrence may be reduced.

SUMMARY

One hundred and ten cases of coronary thrombosis with myocardial infarction have been studied. Sixty patients received the accepted treatment for coronary thrombosis. Fifty received the usual treatment plus dicumarol sufficient to maintain their plasma prothrombin activity at 35 to 50 per cent of normal. The incidence of clinical embolism was 16 per cent in the nondicumarolized group and 2 per cent in the dicumarolized group. The mortality rate in the nondicumarolized group was 20 per cent and in the dicumarolized group was 4 per cent.

We have not been impressed by a quicker return of the electrocardiographic tracing toward normal in the dicumarolized patients compared to those not receiving the drug.

CONCLUSIONS

1. We have observed an increased clotting tendency in most of our cases of acute coronary thrombosis. This is manifested by a decrease in the prothrombin clotting time of diluted (12.5 per cent) plasma.
2. Dicumarol can be safely administered to patients with coronary thrombosis to disrupt this increased clotting tendency.
3. The incidence of embolism as a complication of coronary thrombosis has been significantly reduced in this series of cases by maintaining the prothrombin activity between 35 and 50 per cent of normal during the period of active treatment and early convalescence —a period of six weeks.
4. Digitalization for congestive failure in coronary thrombosis increases the incidence of thromboembolic complications. This hazard may be nullified by the dicumarolization of such patients.
5. Few toxic reactions have been noted in this series. The drug can be administered, if desired, for an indefinite period without ill effects.
6. A comparison of 50 dicumarolized patients with 60 nondicumarolized patients reveals a reduction of embolic phenomena to one eighth and mortality rate to one fifth in the former. Such reduction appears sufficiently significant to warrant further clinical evaluation of this anticoagulant.

NEW OPPORTUNITIES FOR PHYSICIANS IN THE VETERANS ADMINISTRATION

MAJOR GENERAL PAUL R. HAWLEY
Chief Medical Director, U. S. Veterans Administration
United States Army

With the demobilization of our armed forces approximately 15 million more Americans will become eligible for the medical care offered by the Veterans Administration. When the 15 million veterans in the process of demobilization are added to the 4 million veterans of previous wars, it becomes evident that the medical task of the Veterans Administration is both a challenge and an opportunity. It is a challenge to the nation to provide efficient and advanced medical care to those who have given so much for their fellowmen, and it is an opportunity for the physicians of our country to become part of a medical organization which offers unparalleled opportunities for satisfying medical practice and fruitful clinical investigation.

A public law recently passed by the Congress and approved by the President provides for increased opportunities for physicians in the newly created Department of Medicine and Surgery of the Veterans Administration. The law provides for a new salary scale commensurate with training and experience. In recognition of the value of the specialized training and experience of those certified by the American specialty boards, the law provides for a 25 per cent increase in base pay over those given in the accompanying table.

Physicians in the service will be encouraged to train for certification in the specialty of their choice. In the case of physicians already certified as specialists, original appointments will be made in the full grade or higher. While promotions to positions of higher grade are to be based on merit alone, regular salary increases within grade are provided for as shown in the table. Whenever possible, appointments in specialties and to hospitals in particular geographic areas will be made in accordance with the desires of the applicant.

Rates of Pay

Grade	Pay per Annum *	Qualified to Be
Chief	$8,750-$9,800	Clinical director or chief of service in large hospital; a teacher
Senior	$7,175-$8,225	Chief of service in medium sized hospital or chief of section in large hospital; a teacher
Intermediate	$6,230-$7,070	Chief of service in small hospital or chief of section in medium sized hospital; a teacher
Full	$5,180-$6,020	Assistant to chief of service or section
Associate	$4,300-$5,180	Senior ward officer
Junior	$3,640-$4,300	Junior ward officer

* Pay increased with length of service within these limits.

The magnitude of operations of the Department of Medicine and Surgery, operating as it does ninety-eight hospitals containing 85,000 beds, offers an unusual opportunity for clinical practice and investigation. The opportunity to practice medicine untrammeled by considerations of the ability of the patient to pay for expensive laboratory and x-ray studies is one which many physicians will find particularly satisfying. The large number of patients to be cared for and the unequaled facilities for continuous follow-up studies possessed by the Veterans Administration should make the service particularly attractive to those interested in clinical research. Recognizing that practice deteriorates when theory languishes, encouragement will be given to those capable of and interested in independent investigation.

In order to provide the most advanced and efficient care for its patients, arrangements are being made for affiliation with medical schools and medical centers by those hospitals near such institutions, and wherever possible new hospitals will be built in close proximity to such centers. The daily association with recognized authorities in medicine cannot but be stimulating to the physician and will give him professional associations of lasting value. As soon as certain hospitals are certified by the appropriate boards, residencies for recent graduates will be offered. For those interested in teaching, this plan will provide a pleasant opportunity for the instruction and guidance of young men embarking on a medical career. Since the practice of good medicine must be a continuing educational process, arrangements will be made for physicians to attend courses of study in Army, Navy, Public Health Service, Veterans Administration or civilian hospitals at the expense of the government. In order that its physicians may remain in the advancing front of medicine, arrangements for attendance at medical meetings as part of their official duties will be made.

It is evident that the reorganization of the medical services of the Veterans Administration imposes many problems, but it is at the same time an opportunity which I feel must not be allowed to escape. It is an opportunity to mold an organization to meet our new needs with the same determination and resourcefulness which physicians have always applied in the practice of their profession. It is my determination that the service shall at all times be sensitive to the ever advancing boundaries of medical knowledge and that it shall approach its problems in the spirit of the scientist. Such a working approach, I believe, will make for efficient medical care for patients and satisfying professional practice for physicians. I am convinced that the two are synonymous.

It is natural that physicians are interested in the attendant circumstances of their employment, and an organization conscious of the intimate relation between efficient work and the physical and mental well being of those who make up its very structure can be no less so. It is believed that the salaries already mentioned are equal to and in many cases higher than those which can be earned in civilian practice, particularly when it is realized that they are net and require no deductions for office rental, equipment, drugs and clerical or nursing help. The retirement provisions are those of the federal Civil Service and are based on a 5 per cent deduction from salary. Leaves for vacation and illness are the same as for all Civil Service employees. When physicians are transferred from one hospital to another, the expense of moving dependents and household goods is borne by the government.

The basic requirements for appointment as a physician in the Department of Medicine and Surgery are few. The physician must be a citizen of the United States, a graduate of a school of medicine approved by the Administrator of Veterans Affairs and must have completed an internship satisfactory to the Veterans Administration. He must hold a license to practice his profession in a state or territory of the United States or in the District of Columbia. He must meet the physical standards required by the department or, in the case of those recently separated from the armed forces, must present a copy of the final type physical examination of the Army or Navy completed within ninety days of the date of his application.

An outline of the procedure to be followed and the forms necessary for application may be secured by writing to or appearing in person at any office of the Veterans Administration. Appointments to the junior and associate grades will be made by veterans' hospitals or local offices subject to approval of the central office. Appointments in higher grades will be made by the Chief Medical Director with the advice of special consultant boards. Specialists certified by a board will not be offered an appointment at less than full grade. Applications and supporting documents for such higher grade appointments should be sent by air mail to the Chief Medical Director, Veterans Administration, Washington 25, D. C. Applicants will then be notified of the grade of the appointments offered and of their hospital assignments.

Severe Anxiety States.—Severe anxiety states produce an intensely striking, unforgettable picture. Terror stricken, mute and tremulous, these patients closely resemble those suffering from an acute psychosis in a state of panic. In fact, such patients frequently return from the front with the erroneous diagnosis of schizophrenia on their emergency medical tags. There are coarse tremors of the extremities. The facial expression may be vacuous or fearful and apprehensive. Speech is usually impossible except for a few stuttering attempts to frame an occasional word; nevertheless the patients persist in attempting to communicate with attendants. Some may be able to write although unable to talk. Sudden fits of crying or laughing may occur without reason. The behavior is extremely bizarre and attitudinizing, with periods of excessive activity characterized by running about the ward and leaping over beds. —Grinker, Roy R., and Spiegel, John P.: War Neuroses, Philadelphia, Blakiston Company, 1945.

Clinical Notes, Suggestions and New Instruments

HYPOGLYCEMIA DUE TO INSULAR ADENOMA OF PANCREAS

HARRY E. ISAACS, M.D.
Attending Surgeon, Beth Israel Hospital
New York

Hyperinsulinism[1] is most frequently caused by a benign adenoma of the beta cells of the islands of Langerhans or by a carcinoma of the islet cells.[2] If the suspected adenoma can be found, the treatment is simple and effective—the malignant group requires radical resection of the pancreas and duodenum with a prognosis as different as is the procedure. It seems advisable to separate these widely divergent lesions and group their reports under the title of the causative lesion rather than under the symptom which may be produced. A review of all cases of benign adenomas has been brought up to January 1944,[3] 127 in number, which includes Whipple's[4] listing of 103 adenomas in a series of 160 cases of islet tumors. In this report there are 27 cases of hyperinsulinemia due to carcinoma and 22 of suspected carcinoma, 49 cases out of a total of 176, in which the symptom was not due to benign adenoma. Similarly, carcinoma of the islet cells may be unattended by hyperglycemia.[5] The rarity of the successful surgical cure warrants the presentation of an additional case.

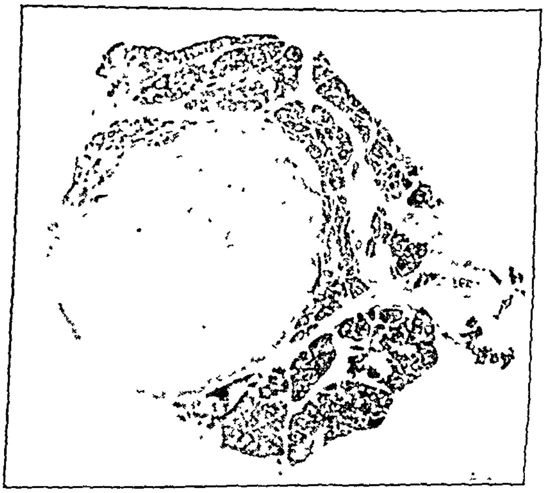

Fig. 1.—Appearance of specimen magnified 4 7 times.

REPORT OF CASE[6]

R. T., a woman aged 55, married, mother of 4 living healthy children, born in Russia, emigrating at the age of 22, was operated on during her first pregnancy in 1914, the appendix being removed for an "extrauterine tumor." In 1926 a panhysterectomy and in 1934 a cholecystectomy were performed Soon after the third operation, attacks occurred at intervals of three to four weeks, characterized by weakness, dimness of vision and cold extremities, merging into a deep sleep of five to six hours from which she awakened torpid and lethargic. Anorexia and nausea followed, as well as a sense of severe pressure in the right temporoparietal region. Amnesia during the attack was partial or complete. Attacks occurred only during the day and seemed to be induced by heavy work.

[6] Case presented at the clinical conference of the Beth Israel Hospital, May 20, 1940.

Her first admission to the Beth Israel Hospital on June 7, 1937 was to the neurologic service, from which she was discharged after a week with the diagnosis of hysterical amnesia. This has been a not infrequent error in diagnosis, since neurologic and psychiatric symptoms are frequently noted in hyperglycemia from any cause.[7]

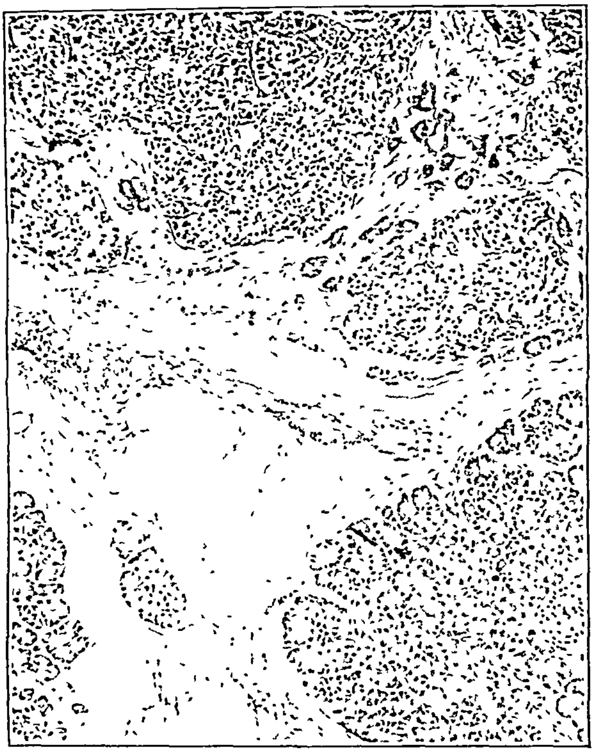

Fig 2—Upper part of section, insular adenoma; lower part, pancreatic tissue with normal islets

Examination of the patient, who was well developed and well nourished, showed few findings related to the symptoms. She was alert, intelligent and cooperative except in discussion of the cause of her emotional disturbances. Blood glucose was 56, 59 and 66 mg. per hundred cubic centimeters. The glucose tolerance test is noted in the table, line 1.

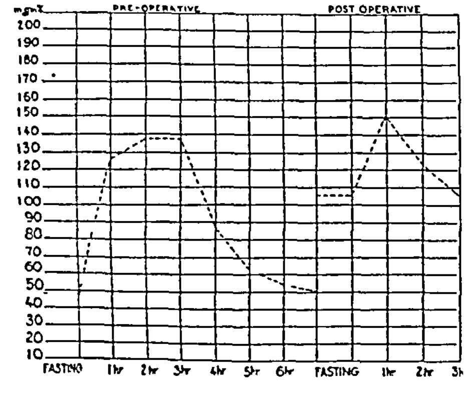

Fig 3—Composite glucose toleration curve.

Her second admission occurred on Dec. 28, 1938 for increasing frequency and severity of attacks at intervals of two to three days or two to three weeks, followed by a comatose state lasting four to six hours. Orange juice seemed to be the only food which hastened recovery. Blood glucose ranged from 43 to 87 mg. per hundred cubic centimeters in casual specimens, averaging 58 mg. per hundred cubic centimeters. The glucose tolerance test, line 3 in the table, required six hours for a return to the fasting level. One examination of 50 mg. per hundred cubic centimeters contained 20.2 mg. of nonfermentable reducing substance. Blood amylase 12 units at 37 C. and urine amylase 1,200 indicated a deficiency of starch-splitting enzymes. The blood sugar on an all starch diet was 43 mg. per hundred cubic centimeters and on monosaccharine 53 mg. per hundred cubic centimeters. At no time was sugar, acetone or diacetic acid present in the urinalysis. The basal metabolic rate was minus 7 and minus 3 per cent.

Her third admission occurred on April 24, 1940 for a typical symptom complex[8] of hypoglycemia and blood sugar levels persistently below 30 mg. per hundred cubic centimeters. A diagnosis of hyperinsulinism was made and, after consultation, the patient was transferred to the surgical service with the diagnosis of benign islet adenoma of the pancreas. The details of the history given to the house surgeon were overheard by a patient in an adjoining bed, a young person with severe diabetes, who volunteered the observation that the symptoms were the same as her own after an overdose of insulin.

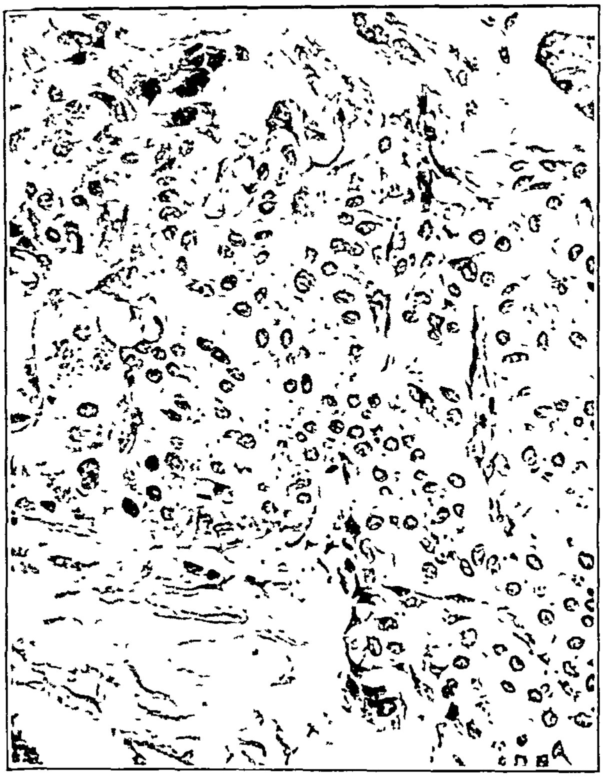

Fig 4—Insular adenoma. Characteristic structure of islet tumor.

Operation was performed on April 29, 1940. Spinal anesthesia was administered with 11.5 cc. of Jones solution. The cholecystectomy scar was excised, exposing component parts of the abdominal wall. Extensive firm adhesions of the omentum were separated from the parietal peritoneum, the under surface of the liver and the duodenum In the head of the pancreas, below the arch formed by the first two portions of the duodenum, an area about 1 cm. in diameter differed in consistency from the adjacent pancreas. This was pointed out to the staff assistants, who were not convinced of its presence.[2] In order to expose the tumor, the lower edge of the first and second portions of the duodenum were freed from the pancreas and the tumor, encircled by a rim of normal pancreas, excised from the angled bifurcation of a large branch of the superior duodenal artery. Defect in the pancreas was sutured with interrupted 000 chromic catgut. The abdominal wall was sutured in layers, without drainage, catgut throughout except for three 30 gage wire tension sutures. The duration of the operation was forty-five minutes.

[7] Bothe, F. A.: Surgery in Metabolic Disease, Internat. Abstr. Surg 78: 461-476, in Surg., Gynec. & Obst., June 1944

[8] Banting, F. G., and Best, A. H: Internal Secretions of the Pancreas, J. Lab & Clin. Med 7: 251-266 (Feb) 1922.

The pathologic examination was made by Dr. Albert Plaut. The specimen was a piece of glandular tissue measuring 23 by 18 by 14 mm. A previous incision partly bisected it. On completion of the incision an almost spherical nodule, 12 mm. in diameter, was found centrally located in the specimen. It was clearly and sharply demarcated from the surrounding lobules of glandular tissue. The glandular tissue was the dull yellow-brown of normal appearing pancreas. The nodule was almost homogeneously gray, except for a few radiating, more shiny gray strands, which appeared to come from the center toward a pseudocapsule. Adherent to the entire specimen was a length of blood vessel, measuring about 1 cm.

A skin flap was 19 cm. long and 1.5 cm. wide, together with underlying fat.

Microscopic examination revealed that the tumor consisted of cords and heaps made up of cells of islet type. The topographic relation between cells and capillaries was the same as found in normal islets. The cellular masses were separated from one another by fairly dense connective tissue. Pseudoglandular structures were numerous, notably in areas where the tissue appeared choked by fibrosis. The cellular pattern was regular. A narrow zone of pancreatic tissue at the edge of the nodule was rather fibrotic; otherwise the surrounding pancreatic tissue appeared normal, with moderate obesity. The islands of Langerhans in this tissue were normal.

The postoperative course was free from immediate complications. Blood sugar eight hours after glucose infusion reached 194 mg. per hundred cubic centimeters. There were no further symptoms of hypoglycemia. The patient was alert, responsive and "interested in living." Two weeks after operation signs of a low grade intra-abdominal infection appeared and on May 20 an incision was made into a localized collection of chocolate colored opaque fluid containing autolyzed fragments impossible to identify but which did contain amylase, lipase and trypsin. The wound healed rapidly and the patient was sent home on June 13, 1940.

SUBSEQUENT COURSE

Seven months later the patient was operated on for a fistula-in-ano subsequent to ischiorectal abscess four months before. The glucose tolerance test is noted in the table, line 8. The patient was readmitted for follow-up May 4, 1945, five years after operation. She has been continuously symptom free and in excellent physical and mental health. The glucose tolerance test is noted in the table, line 9.

The glucose tolerance tests are vivid in their difference before and after operation. These examinations should have been made at the same intervals and continued for a six hour period. The fasting blood sugar levels below 30 mg. per hundred cubic centimeters on all tests made during the week before operation are as clearly indicative of the disease as are the postoperative levels of 90 to 120 mg. per hundred cubic centimeters indicative of the cure. The first postoperative test (line 5 in the table) may have been due to the infectious process in the region of the pancreas. By eliminating the figures in this test, an average is shown which is more fairly indicative of the metabolic change and is perhaps more nearly correct. A striking feature in the glucose tolerance curves is that in preoperative tests the fasting blood sugar level was never reached in less than six hours, whereas after operation the fasting levels were reached in three hours or less.

COMMENT

The progress in the recognition and cure of hypoglycemia due to hyperinsulinism was promoted by Banting,[8] who postulated the condition in 1921. It was pathologically demonstrated in C. J. Mayo's case[9] in 1927 and first cured by Roscoe Graham[10] in 1929. Whipple's numerous contributions have greatly stimulated interest in the surgery of the pancreas.[11] A number of cases of hyperinsulinism have been successfully treated by resection of the pancreas[12] in which neither an adenoma nor a carcinoma of the islet cells has been found. A large percentage of islet adenomas not found at operation have been found at a second operation or on autopsy. Frantz[2] reports 70 islet adenomas in which series 46 were found at operation and 24 found at autopsy. Whipple[13] reported 82 cases in which 47 were not found, of which 6 were located at reoperation, 4 in specimens of resected pancreases and 4 on postmortem examination. It is obviously difficult to locate a benign islet tumor, a difficulty increased when such tumors are multiple or when present in aberrant pancreatic rests.[7] Since the tumor may differ but slightly from the consistency of the adjacent pancreas, as in the case presented in this report, a finer tactile sense must be developed by the experienced surgeon.

SUMMARY

Benign adenomas of the islet cells of the pancreas causing hypoglycemia by hyperinsulinism should be separated in reports from the malignant tumor of the pancreas, which occasionally give a similar symptom complex but from which the treatment differs radically. The lesion gives a typical and easily recognizable symptomatology.

Up to January 1944, 127 islet adenomas have been reported to which the case herewith presented has been added, with a report of a five year cure.

All cases of hyperinsulinism due to benign adenoma may at present be cured by surgery, depending only on the ability to locate the tumor.

1150 Park Avenue.

Council on Physical Medicine

The following article has been adopted by the Council on Physical Medicine:

The Council wishes to express its appreciation for the valuable cooperation of the Consultants on Ophthalmic Devices in reviewing this article. The consultants are Drs. Walter B. Lancaster, chairman; Thomas D. Allen, Charles A. Bahn, S. Judd Beach, Conrad Berens, Frederick C. Cordes, Alfred Cowan, William H. Luedde, Lawrence T. Post and Avery D. Prangen. This paper was also submitted to the American Orthoptic Council and embodies the criticisms and suggestions of that council.

Howard A. Carter, *Secretary.*

WHAT IS ORTHOPTICS?

WALTER B. LANCASTER, M.D.
Boston

Orthoptics deals with defective habits of seeing, defects of binocular vision and defects of ocular motility. How perfectly adapted it is to deal with many of these defects will become apparent when the nature of the defects is made clear. It will also become clear that much which passes for orthoptics is far removed from the real thing.

But first a few words about the history and organization of orthoptics in America. There is a Council on Orthoptics composed of twelve ophthalmologists and four associates who are orthoptic technicians. The ophthalmologists are elected one annually for three years by each of the four interested national medical societies. The associate members are chosen from the American Association of Orthoptic Technicians. One every year for three years is selected by the council; the president of the Association of Orthoptic Technicians, is a member ex officio. Thus the orthoptic technicians have the selection of one associate member of the council.[1] The council exercises general supervision over orthoptics. In particular it issues certificates to orthoptic technicians who may apply and are found competent and who comply with the regulations of the council. At present about seventy-five orthoptic technicians hold certificates, but many of these are not active. However, there is no legal restriction limiting the practice of orthoptics, and most of the orthoptic practice is carried on by optometrists, nurses, office assistants and doctors. Too often this consists in the use of some more or less elaborate apparatus or automatic machine which they are taught to use by the manufacturer's traveling representative. The patient comes day after day and is placed before the apparatus or given pictures to look at with some form of stereoscope. Of actual teaching in the proper use of the term there is very little because the operator has hazy, often erroneous, conceptions of what is wrong and what needs to be done to correct it.

Inevitably one judges orthoptics by the work of such technicians as one has seen. There are only a few who are masters of the best technic, and therefore many doctors, even ophthalmologists, have no first hand knowledge of good orthoptics and on the basis of their own limited experience some condemn the whole thing, some condemn various parts.

The best modern orthoptics was developed in London under Miss Maddox, daughter of the ophthalmologist famous for his work on ocular motility. There is also a French school, but not much has been done by German or other European ophthalmologists. Several American orthoptists have studied in Europe and brought back the ideas of the Maddox school to this country. The oldest school of orthoptics in this country is in New York at the New York Eye and Ear Infirmary. Others have been started at St. Louis, Washington, D. C., Milwaukee and Rochester, N. Y.

Since so much of the orthoptics is done in doctors' offices by technicians whose duties are not limited to orthoptics, and since the training and certification are supervised by ophthalmologists who are not themselves expert in the technic of orthoptics, it was inevitable that the ophthalmologists should overemphasize that part of orthoptics on which they are best informed. Thus they stress the diagnosis of defects of ocular motility and the measurement of deviations which are the province of the doctor and lay too little emphasis on the art of the technician in dealing with the patient. Many doctors have found it convenient to assign to the assistant who does the orthoptics other duties, such as perimetry or refraction or assistance in history taking or records. The remainder of this paper will be limited to orthoptics properly so called.

The defects of binocular vision or of ocular motility are divided into two groups: heterotropia and heterophoria. For the purpose of this paper it is unnecessary to enter into the details of diagnosis and the many subdivisions of classification. What is necessary for a clear conception of orthoptics is an understanding of the nature of heterotropia and of heterophoria in order to appreciate the treatment, since orthoptics is a system of treatment, not a system of diagnosis.

HETEROTROPIA

Ocular motility is necessary because the retina is not equally sensitive all over. The macular area and especially the fovea is far more sensitive and has more acute vision than the periphery. When one wishes to scrutinize an object, the eyes have to be moved so that the image of the object falls on the fovea. This is accomplished by moving the eyes in their orbits and usually the head as well. It is called fixation. Since there are two eyes, it is necessary for normal binocular vision that the two fixate the same object. Otherwise, if the object is imaged on the fovea of one eye and not on the fovea but somewhere on the periphery of the other retina, diplopia and a disagreeable sensation result. To take care of this, the two eyes are linked together in their innervation as a single organ (the binoculus). The innervation necessary for the movements of fixation is reflex and automatic and goes to the two eyes equally so that they move together. Thus if one eye is covered and the other fixates, both eyes move and when the cover is removed that eye is seen to be fixating the same object as the fixing eye. This is the ideal coordination. As a matter of fact it is never exact. The covered eye never assumes the exactly correct position. If the deviation is less than ¼ or ½ degree it is usually disregarded and the position is called orthophoria. If the deviation is one of divergence it is called exophoria and if it is one of convergence it is called esophoria, while a vertical divergence is a hyperphoria.

---

[1] The following have been members of the council arranged in order of years of service on the council; the names starred are the present members: Hardy,* Prangen,* Dunphy, Hitz,* Allen,* Costenbader,* Cordes, Cowan, Cushman,* Fralick,* McCaslin,* Vail, Wheeler, Clay, Dunnington, Gifford, Goar,* Gradle,* Guibor, Lancaster,* Boyes * and Bulson. Associate members: Miss Stark,* Miss Sobacke, Miss Wells, Miss Dicke, Miss Lancaster, Miss Brunn, Miss Powell * and Miss Enos.*

Another reflex is needed to correct this deviation which occurs when the fixation reflex alone is acting. This is the fusion reflex. The stimulus is the presence of two images of an object not on corresponding points of the two eyes, for example one on the fovea of one eye and the other not on the fovea of the other eye. This double stimulus automatically gives rise to innervation, which moves the eyes the (usually) slight amount needed to correct the deviation. The deviation which exists when there is a phoria is often spoken of as a tendency to deviate, since it is not present but latent so long as fusion is allowed to act. Modern physiologists stress the important fact that it is a real deviation and not merely a tendency to deviate. The essential thing is to recognize the role of fusion. Without fusion the deviation is very real and actual—not a mere tendency.

If the deviation is present even when the eye is not covered, it is called heterotropia or tropia or strabismus or squint. The difference between heterophoria and heterotropia is this, and it is quite important to understand it: when one eye is covered and a person looks at an object, the fixation reflex is acting. When both eyes are permitted to look at the object, fusion reflex acts also. In strabismus the fusion reflex does not overcome the deviation—fusion fails. In heterophoria the fusion reflex is effective and does overcome the deviation so as to produce single vision. In the absence of the fusion reflex the eyes assume the fusion-free position,[2] any phoria which is present becomes manifest and so can be measured. The simplest way to find the fusion-free position is to cover one eye and see what happens behind the cover. As the cover is quickly removed the eye will be seen to make a movement of redress to correct the deviation (the phoria).

Besides the use of the cover there are other ways of detecting and measuring the deviation which exists in heterophoria. In all cases what is done is to eliminate the fusion reflex; some methods do this more effectively than others.

The importance of measuring the phoria consists in this, that it is a means of ascertaining what the task is which has to be performed by the fusion reflex in order to get binocular single vision. Whether this task is easy or difficult, that is, whether it will cause symptoms, depends on two things: first, on how large it is. This is measured in prism diopters. It is the strength of the prism which will correct the deviation. Second, on the ability of the patient to overcome the deviation. This is the amplitude or range of fusion.

The disorders of motility and binocular vision in which orthoptics is interested are chiefly concerned with fusion. Fusional power is capable of considerable increase by suitable exercises. The power to fuse is measured by the strength of prism which can be overcome in the interest of single binocular vision. It is called the amplitude of fusion. Thus, if a person can overcome a prism of 30 diopters base out but no more, he has a prism convergence of 30 diopters. If he can overcome a prism of 6 diopters base in but no more, he has a prism divergence of 6 diopters. The measurement and interpretation of the amplitude of fusion require considerable skill and understanding.

By following the natural history of a typical case of strabismus one can get a good idea of the field of orthoptics and of the importance of seizing the best time, the right age, to teach any particular skill. This will be followed by illustrations drawn from heterophoria, which is the other important field of orthoptics.

In neither case will any attempt be made to give a complete account of the various therapeutic measures available to the orthoptic technician. Rather the attempt will be made to show that the trained orthoptic technician has such an understanding of the physiology, normal and pathologic, of the visual act that she can put her finger on the defective function and apply methods of treatment proved by experience to be effective in restoring that function to normal performance. This in contrast to the untrained technician, who has one or several pieces of apparatus he uses for all cases routinely.

DEVELOPMENT OF THE VISUAL APPARATUS

At birth the normal child has very imperfectly developed eyes. There is no macula as yet, the optic nerve fibers are not yet myelinated, the ciliary muscle is not ready to function, the visual acuity may be estimated as of the order of 6/1,000 (practically blind). By 6 months the acuity may be 6/300, at 9 months 6/72, at 2 years 6/12, at 3 years 6/9, and not much before 5 years of age is vision equal to 6/6, while acuity as well as other visual functions continue to improve for several years longer before reaching their maximum efficiency.[3]

Since the anatomic parts of the visual apparatus are not in condition to function well, it is obvious that the physiologic side of seeing is quite rudimentary at birth. Hand in hand with the growth and development of the visual apparatus anatomically is its development physiologically. Here it is important to differentiate those functions which require only the passage of time and the completion of the anatomic apparatus for becoming perfect and those functions which require usage, practice, learning. Thus the finer movements of the vergence reflex (binocular fixation of near objects) cannot develop before the structure of the fovea is complete; but neither can they develop without usage. A useful classification is that between conditioned and unconditioned reflexes. The unconditioned reflexes are inborn and develop independently of usage; examples are the pupillary reaction to light and retinal adaptation to light and darkness. The conditioned reflexes are dependent on usage and on reinforcement. A variety of possible alternatives may present themselves, and which particular type of reflex prevails depends on the "reinforcement" which goes with it, depends on which of the possible alternatives gives the most comfortable easy working of the apparatus, on which gives the greatest reward or satisfaction. This is called reinforcement. If an ocular reflex develops only on usage, then if there is no usage there is no development. Moreover, if the reflex for some reason fails to develop in its proper sequence it may become "extinct"; that is, it may not be capable of restoration by usage attempted at a later date.

A few examples will show the practical bearing and importance of these basic principles. The first example deals with amblyopia ex anopsia and also illustrates the importance of suppression, which will be mentioned again and again, since it is the most important feature of orthoptics; first because more patients have it than any other orthoptic disability, second because there is no other way to cure it except by orthoptics and third because it is so neglected by ophthalmologists as a source of ophthalmic failure.

---

[2] The position of the eyes when fusion is eliminated is called the fusion-free position. It is also called—miscalled—the position of rest. This is misleading, since it implies that the eyes are at rest, whereas they are by no means at rest since they are acting under the fixation reflex.

[3] Chavasse, F. B., in Worth's Squint or the Binocular Reflexes and the Treatment of Strabismus, ed. 7, Philadelphia, P. Blakiston's Son & Co., Inc., 1939, p. 107.

1. Suppose at 2 years of age a child ceases to use one eye. Vision may be 6/12 in each eye at this stage of development. Suppose that for some reason the child learns to suppress one eye. From that time this eye ceases to progress toward better vision. Not only that, but it actually loses some of its already acquired vision and in a few months the vision in the eye that is being suppressed will have dropped to say 6/18, while the vision in the eye that is being used every day has progressed to 6/8 and as time goes on to 6/6. Meantime the unused eye has dropped farther back to say 6/20 or 6/30 or even less.

If now at the age of say 4 years the good eye is occluded by a suitable cover worn continuously all day, the patient is forced to use the poorer eye and it rather rapidly improves under usage. In a few weeks or months it will be back where it was when usage was first interrupted, viz. in this case vision equals 6/12. It will continue to gain, but more slowly, until it overtakes the other eye.

But if the occlusion of the good eye is not begun until the stage of normally developing visual acuity is passed—say at 10 years of age or older—the progress of the poor eye, even though it is now being used constantly, will be very slow and will seldom reach the normal which could be attained if the treatment was given during the period of natural development of visual acuity.

2. A second example is the development of the near reflex, which comprises contraction of the pupil, convergence and accommodation. The convergence-accommodation relationship, which becomes such an intimate relationship in the normal individual, is present only potentially at birth. Various obstacles may interfere with the development of this reflex. Suppose the obstacle is the common one of hypermetropia. As the ciliary muscle develops it becomes possible to focus the image on the retina with more precision. As the macular area develops so that it is capable of utilizing a clearer image, the inducement, the reward, the reinforcement become greater for good focusing or accommodation. The child finds that it sees better by accommodating, thus securing a better image on the retina. It also finds that by converging more strongly it is easier to accommodate. This greater ease of accommodation is an effective reinforcement of the convergence. However, the excess of convergence produces diplopia. Unless this is taken care of—eliminated—the reward is lost, the reinforcement is nil. To eliminate the diplopia is easy by the method of suppression. Then the reward is satisfactory and the reflex is reinforced and soon becomes established. The child is now cross-eyed but is well satisfied because he sees more clearly and comfortably.

3. A third example is furnished by anomalous correspondence. Normally an object seen by both eyes is imaged on corresponding points and is seen single, thanks to the fusion reflex; but in this case the object is imaged on the fovea of one eye and off the fovea of the other eye; result, diplopia. The patient has to learn how to localize in the same place or, rather, in the same relative direction, a stimulus impinging simultaneously on the fovea of one retina and on an eccentric element of the other retina. If the strabismus has developed at a sufficiently early age and if he is adaptable and there is time enough, he usually develops a sort of makeshift binocular vision. Burian has listed the conditions necessary for this to develop as (1) the presence of a certain amount of binocular cooperation—binocular vision must have developed to a certain stage (or be inborn); (2) suitable age and adaptability of the patient; (3) the time elapsed since strabismus became manifest; (4) the type of motor anomaly, and (5) the type of test used, all having important influence on the findings. First he learns to suppress the detrimental image on the fovea of the deviating eye, which conflicts with the desired image seen by the other eye (the straight or fixing eye) on its fovea. Second, an attempt is made to set up a new sensorial relationship whereby some point of the retina of the deviating eye (it tends to be that on which the image of the object being fixated by the straight eye now most frequently falls) learns to see it in the same direction as the straight eye sees it. This is a secondary, new and anomalous way of seeing or projecting it. It is usually called anomalous correspondence and it is one of the stiffest stumbling blocks to the cure of strabismus with restoration of binocular single vision.

What I wish to stress is that the acquisition of anomalous correspondence is an example of learning to see by usage, an example of forming a conditioned reflex. The reinforcement which fosters the formation of this reflex is first the satisfaction of the strong urge toward binocular vision which exists at this age or stage of development even though circumstances make normal binocular vision impossible and, second, the satisfaction of getting rid of a conflicting though fainter image, which tends to be superposed on the image of the object being fixated by the straight eye.

In the same way one should stress the fact that the technic to be followed in treating this condition depends on an understanding of the physiology, normal and pathologic, an understanding of the habits involved and the technic of changing (reforming) habits. The suppression of the foveal image of the deviating eye must be overcome. The patient must be made to become conscious of the stimulation of the fovea and learn to suppress instead the anomalous image (which is always fainter, since it is peripheral, not foveal).

4. A fourth example is reading, which after all is just a complicated conditioned reflex. The apparatus comprises (1) the eye—the visual apparatus in the limited sense—and (2) the neuronic pathways in the brain which are an essential part of seeing in the larger sense of perceiving and understanding what is looked at.

The anatomic components of the visual apparatus and the general layout of the neuronic pathways develop, to a large extent, unconditionally, solely as a matter of time; but, for reading, a further development of the neuronic pathways and a coordination of different parts of the brain, conditioned on usage, an accumulation of memories and experience, all are required for skilled performance. Ordinarily, the process of acquiring this conditioned reflex, the process of learning to read, goes on fairly smoothly with a succession of adjustments and adaptations and acquisitions which take years to perfect.

There may be obstacles, however, which are hard to overcome. The neuronic pathways may be confused, a child may be left handed, may have crossed dominance between eye and hand, resulting in reading difficulty, mirror writing or the like. To overcome these and other difficulties is the task of the specialist in reading difficulties, which may be regarded as a branch of orthoptics but which is not usually taught in the courses for orthoptists or required in the examination for the certification of orthoptic technicians.

These four examples suffice to show the province of orthoptics in the treatment of defective habits of seeing and of disturbances of binocular vision and motility in children.

The principle then is that both anatomically and physiologically the development of the visual apparatus is incomplete at birth. As time goes on, some of the processes automatically are perfected, some become perfected only by usage, by practice. It is not assured that they will progress in the normal or ideal way. Obstacles may turn the course of development into wrong channels. It is the province of the orthoptist to untangle the complications and lead the child into the normal path to the acquisition of normal reflexes. Thus the cross-eyed child must be taught (forced) to use the amblyopic eye and so recover its ability to see. He must be taught not to suppress but to see double instead, as a normal child does if his eyes deviate; he must be taught to overcome the diplopia by fusion and binocular vision as a normal child does, rather than by suppression. This is done first on a major amblyoscope, and then the child must be further taught to see properly "off the machine" in casual seeing. Naturally the different types of strabismus require different and appropriate methods of treatment. To enumerate them is beyond the province of this paper.

HETEROPHORIA

To return to the other type of motor defect—heterophoria. There are three ways of treating a phoria: (*a*). By operation one can actually reduce the deviation. The eyeball is shifted in the orbit to a position nearer orthophoria, with the result that now fusion has a smaller adjustment to make. (*b*) The adjustment can be made in part by prisms incorporated in the spectacles. This reduces the task of fusion. (*c*) The amplitude of fusion can be increased by suitable exercises so that the task of adjustment to be made by fusion, though no smaller, is easier because the capacity of the adjusting mechanism is greater. This is the function of orthoptics. By suitable exercises in the office and at home it is possible to increase rapidly the amplitude of fusion, and it is found that the patient's task of dealing with heterophoria becomes much easier and the symptoms of eyestrain are relieved. Sometimes not only is the amplitude of fusion increased but the amount of deviation (phoria) may actually be diminished.

Right here a prevalent misconception should be mentioned. It is commonly (and naturally) thought that the increase in range or amplitude of fusion is the result of stronger muscles. According to this view the task of the orthoptic technician is to strengthen certain weak muscles, and the explanation is given to the patient that the eye deviates because of a weak or lazy muscle. This naive conception misses the mark. It leads the attention in the wrong direction. To be sure one function of exercises is to strengthen muscles, but much more commonly their function is to increase the control of the muscles, the coordination of the movements by the nervous system. For example, in practicing the piano one learns to manage the fingers; proficiency as a performer is not a matter of strong muscles but of perfection in the control and use of the muscles. So with drawing, writing, dancing, juggling: practice and exercises and teaching are aimed at the control or coordination of the muscles. The mechanism for ocular movements is a neuromuscular mechanism. The muscles are over a hundred times as powerful as is needed to move the eyeballs if all the fibers of a muscle contracted at once. Hence only a small percentage of the muscle fibers have to act at one time, and as the other fibers are resting they are well able to perform this task when their turn comes and the first lot are allowed to rest. It is to the "neuro" part of the mechanism, not the muscular part, that attention should be directed.

This naive conception of a hypothetical weakness of the muscle or muscles is prevalent among surgeons. They conceive of a tenotomy as aimed at weakening the muscle tenotomized or receded and they conceive of a resection or advancement as strengthening a muscle. The correct conception of shifting the position of the eye in the orbit to a position nearer the zero position (that is, the position where the deviation is zero and consequently the task of the muscles is greatly reduced) explains why it is so frequently best to combine a tenotomy of the antagonist with a resection of a muscle (Dr. Edward Jackson says always, but nearly always is better, though it lacks the emphasis of exaggeration).

A few examples will make clearer what can be accomplished by orthoptics and how orthoptics and other methods of treatment dovetail together in any well conceived plan of dealing with defects of motility and binocular vision.

Esophoria.—(*a*) This is often amenable to glasses which reduce the accommodation, since reduction in accommodation carries with it reduction of convergence. (*b*) Often there is a greatly diminished amplitude of divergence. While the right eye can be abducted easily to its outer canthus and the left eye to its outer canthus, say 50 degrees either way, yet when prism divergence (often miscalled abduction) is tested, diplopia may come at 1 to 1½ degrees (2 or 3 prism diopters) and, as the prism strength is gradually reduced, recovery of single vision may not occur until zero is reached or even beyond zero. Thus the need is clear of increasing the power of divergence, and since the muscles are amply strong as shown by the abduction of either eye (no paresis) it is possible to teach the patient to use his muscles to better advantage and greatly increase his power of divergence. Exercises on the major amblyoscope and other instruments in the office, and home exercises with prisms base in, are very effective. These should be done say ten times a day for a matter of three minutes at a time. (*c*) Such patients are often greatly relieved by temporarily wearing prisms base out until their divergence is increased by exercises enough to dispense with them.

(*d*) There are a good many cases in which operation is indicated, since it is much more rapid in its results and does not make demands on the patient which the doctor may have difficulty in getting him to meet—indeed, it may be impossible for some busy patients to find time for ten to twelve periods of three minutes every day. One is often surprised at the gain that may come from two or three periods a day, but, if the gain is not satisfactory, operation is the proper alternative. After operation a period of orthoptics is frequently desirable, since the patient has to learn a new way of cordinating his muscles after an operation and since in many cases he continues to fall back on suppression as the easy way to escape diplopia without the effort of fusion. What I wish to emphasize is that treatments by glasses, by operation and by orthoptics need to be combined and are not mutually exclusive.

Exophoria.—This is very successfully treated by orthoptics in many cases. If the exophoria is associated with a decidedly poor amplitude of convergence, the indication is clear that the amplitude of convergence should be increased. The response to suitable exercises given with sufficient frequency is usually prompt and is accompanied by relief of symptoms. Here again home exercises are an important aid to rapid progress. One would not think of learning to play the piano with, say, two lessons a week of half an hour and no home practice. The same is true of acquiring any other skill, as in games. The oftener the movements are repeated, the greater the facility—"practice makes perfect." Many persons with exophoria are helped by wearing prisms base in their glasses.

When time is important and it is not practical to give the needed exercises either in the office or at home, operation offers a prompt and effective treatment, especially for the larger amounts of exophoria too large for prisms in glasses or when convergence may be fair but divergence is excessive. Here again postoperative orthoptics is very useful in securing the best results.

Hyperphoria.—This is often classed as not amenable to orthoptics. The only difference is that it is not so easy and it is sure to take more time and perseverance. Moderate amounts, which are far more common than large amounts, of hyperphoria can be satisfactorily remedied by prisms incorporated in the glasses worn by the patient. Large amounts can be remedied by operation, but orthoptics can help in all these cases since the patient has to learn and learns better under good instruction (skilful orthoptic technician) how to use his eyes under the existing conditions whether with or without glasses or surgery.

SUMMARY

Orthoptics is the art of teaching patients, children or adults, how to use their eyes properly. At birth the eyes, including the neuronic pathways involved in vision, are very imperfectly developed. As they grow anatomically they also develop physiologically. Some of this development is dependent on usage. Development may not progress in the normal or ideal way. Obstacles may turn the course of development into wrong channels. Skilful and understanding guidance by the orthoptic technician can lead the patient into the acquisition of more normal and useful habits or reflexes.

Thus the aim of the orthoptic technician is not the strengthening of some muscle or muscles alleged to be weak but is directed toward teaching the patient better control and coordination, better reflex response to his environment; hence the technician is greatly aided by understanding the physiology of vision and the psychology of teaching and of learning. Some apparatus, such as a major amblyscope, a stereoscope, prisms and various small accessories, are indispensable; but a lot of elaborate "automatic" machines will by no means take the place of intelligent skill under close supervision.

Glasses may help greatly, may be indispensable in some cases, but a surprising number can be taught to use their eyes without the glasses which they had been told were indispensable by some one not well informed on the subject of orthoptics.

Operation often saves much time and indeed makes some cases amenable to orthoptics that would be hopeless without surgery. Thus, refraction, orthoptics and surgery form a powerful team and should always work together.

Just as some surgeons are more skilful operators than others and some specialists are more skilful in measuring and treating errors of refraction and motility by glasses than others, so some orthoptic technicians are more skilful than others and should be allowed to spread the knowledge of their methods by advanced or graduate teaching. There is urgent need for opportunities for graduate individual instruction in orthoptics.

The Council on Physical Medicine has authorized publication of the following report.

Howard A. Carter, Secretary.

HANOVIA LUXOR "S" ULTRAVIOLET ALPINE LAMP ACCEPTABLE

Manufacturer: Hanovia Chemical & Mfg. Company, Newark 5, N. J.

The improved Luxor Professional Model "S" Alpine Lamp is the result of development in this field during the war. The burner itself is an improvement over the former burner in the lamp of the same name and model number, The Journal, May 20, 1939. It starts at the snap of the switch and requires no tilting. The mercury arc is established in a quartz tube between two solid electrodes of the activated type in a mercury vapor atmosphere of high pressure. The lamp develops the characteristic spectrum of a high pressure mercury arc. This lamp is designed to give a complete irradiation of one side of the body at one exposure. The time required according to the firm is thirty seconds on average untanned skin at 30 inches distance.

In a laboratory acceptable to the Council on Physical Medicine, the radiant and electrical characteristics were examined. The particular unit tested had the following data on the name plate on the housing of the control unit: Catalog No. S-2303-AS; Type 20504; Serial No. 1745. The tests consisted of radiometric measurements of the intensity of ultraviolet radiation, of wavelengths 3,132 angstroms and shorter, at a distance of 30 inches from the front surface of the burner, under controlled conditions.

To insure constant operating conditions the lamp was connected to a 120 volt, controlled alternating current supply. The radiation measurements were made by means of a balanced thermopile and filters in conjunction with a Thompson galvanometer. The apparatus was calibrated by use of a standard of radiation immediately after the observations on the sample. The observations were made with the burner in a horizontal position, with the reflector set symmetrically with respect to the horizontal plan.

The following results were obtained:

Line Voltage	Operating Current Amperes	Burner Current Amperes	*Lamp Output at 30 Inches* 3,132 Angstroms and Shorter
112.3	8,175	3.4	2,840 microwatts per square centimeter

Data on current and voltage were taken after a sufficient warm-up period to insure steady conditions. This amounted to at least fifteen minutes.

According to the report of the Council on Physical Medicine of the American Medical Association in The Journal, Jan. 27, 1940, pages 325 and 326, a minimum perceptible erythema is produced in fifteen minutes by 20 microwatts per square centimeter of radiation of 2,967 angstroms, or an equivalent of 58 microwatts per square centimeter of 3,132 angstroms and shorter from a high pressure hot quartz burner. According to these figures an output of 2,840 microwatts per square centimeter at 30 inches is sufficient to produce a minimum perceptible erythema in a little over eighteen seconds.

Actual measurements were made at only one position, but illumination of a large white screen set up directly in front of the lamp showed a remarkable uniform distribution in the radiation pattern.

The Council on Physical Medicine voted to include the Hanovia Luxor "S" Ultraviolet Alpine Lamp (Improved) in its list of accepted devices.

TEMPERATURE RECORDING FOR FEMALE FECUNDITY

van de Velde's observation as to the existence of variations in body temperature during phases of the menstrual cycle was cited in a previous editorial.[1] Rubenstein [2] correlated a study of vaginal smears with a study of basal temperature; he found that the basal rectal temperature tends to drop progressively during the phase of follicle development. The low point in the temperature curve is reached when the follicle matures. Barton and Wiesner [3] found in their studies of the temperature in several hundred women that the body temperature on waking in the morning varies in fecund women with the phases of the menstrual cycle. A relatively high temperature is characteristic of the premenstrual phase, and it persists after conception. Persistent low temperature excludes the diagnosis of pregnancy. The diphasic temperature cycle may persist in cases of amenorrhea, but more commonly amenorrhea is characterized by a monophasic waking temperature record. Certain types of infecundity are associated with absence of the high temperature phase. The transition from the low to the high temperature phase coincides with the ovulatory phase. The occurrence of this shift does not, however, constitute a proof of actual ovulation. The authors believe that the waking temperature record may also be employed in determining the "safe" postovulatory period when conception will not take place.

From the clinical experience of Barton and Wiesner a level of 99 F. or more sustained for more than sixteen days is characteristic of pregnancy. A level of 98.8 to 98.9 F. sustained for more than sixteen days is highly suggestive of pregnancy. They feel that the pregnancy test for chorionic hormone need not be carried out if the waking temperature is still at the low level or below 98.6 F., even though the period is much overdue. The diagnosis of pregnancy based on high waking temperature was in their experience correct in at least 97 per cent of cases. The diagnosis of nonpregnancy has not produced any errors in their experience so far. Sudden fall of the waking temperature after the high temperature has been maintained for sixteen days or more calls for immediate measures to counteract indicated miscarriage. These studies suggest that the waking temperature cycle is closely correlated with the ovarian cycle and that the thermal shift may be used as an indicator of ovulation but not as positive evidence of its actual occurrence. There is no convincing evidence that the waking temperature cycle depends directly on ovarian secretion and that in particular the high temperature phase is evoked by luteinization, with which it corresponds in time. The occurrence of a well defined diphasic cycle with a sustained high temperature phase supports the diagnosis of fecundity but does not establish it in any respect.

Halbrecht,[4] in his clinical study of the relation of ovarian function to body temperature, confirmed the view of van de Velde that the normal temperature curves of women of childbearing age are diphasic. The difference between the temperature level of the postmenstrual and the premenstrual phase seems to be more or less constant in the various cycles of the same woman. He feels that the basal temperature records offer a sufficiently reliable test to check the ovarian function and that this method may be helpful in the study of female sterility. Basal temperature records in his experience are also helpful in the early diagnosis of pregnancy and can be used to test the efficiency of hormone treatment of functional ovarian disorders. The advantage of the method is that it allows one to check the occurrence of ovulation in a large number of menstrual cycles. In an analysis of body temperatures recorded through 271 menstrual cycles by 130 patients suffering from sterility, he found that 238 of these cycles were diphasic and 33 monophasic. Endometrial biopsy was used to check 27 diphasic and 13 monophasic cycles. The same conclusions could be drawn about ovulation in all but 1 case. Of 40 cases of pregnancy, 37 showed a relatively high temperature level (98.6 to 99.3 F.) and in only 3 cases was there a low temperature level.

Thus medicine would seem to have available now a simple, reliable procedure for determining the time of various features of the menstrual cycle. The many applications of this technic in clinical practice will be readily apparent.

THE TREATMENT OF PRIMARY POLYCYTHEMIA OR ERYTHREMIA

The treatment of primary polycythemia by repeated bleeding and the administration of hydrazine derivatives gives only temporary symptomatic relief by mechanically or chemically reducing the amount of the circulating blood or red cell mass. Radioactive phosphorus when obtainable is the treatment of choice at present. The development of more effective and rational therapeutic measures has been prevented by our ignorance of the causation of the disease. Recent experimental studies of Schafer[1] on the effects of the resection of the carotid sinus with the cardioaortic proprioceptive nerves and of the paravertebral sympathetic ganglions and nerves on vasotonus, blood pressure, oxygen metabolism and peripheral blood cell mass throw an interesting new light on the possible genesis of polycythemia and may open a new and promising avenue for its therapy.

Schafer observed that a polycythemic reaction, in addition to hypertension, developed in 40 per cent of dogs in which the carotid sinus and the cardioaortic proprioceptive nerves had been removed. The polycythemic response regressed in these dogs on subsequent complete paravertebral sympathectomy. However, following a proprioceptive depressor neurotomy in dogs previously subjected to a paravertebral sympathectomy and not infrequently showing vascular hypotension as the result of this operation, a polycythemic reaction ensued. The existence of a relation between the autonomic nervous system and the peripheral cell mass was thus established. Schafer applied this new relationship to the treatment of a patient with primary polycythemia. Following a total paravertebral sympathectomy a rapid drop in the number of erythrocytes to a normal level occurred and the associated untoward subjective and objective symptoms disappeared. Although the number of erythrocytes gradually increased again during the subsequent two years, the disabling symptoms did not recur, thereby permitting the patient to do prolonged and strenuous physical labor. Postoperative complications consisted of a temporary disturbance in the sweating mechanism of the denervated parts of the skin and of definite, but transitory, postural hypotension.

It is known that an anoxemic mechanism interfering with the oxygenation of the marrow is responsible for the development of the erythrocytes following a prolonged exposure to vasoactive agents such as epinephrine, amphetamine, ephedrine, posterior pituitary, lead, nitrates or cyanides, to agents and mechanisms impairing the proper oxygenation of the blood such as carbon monoxide, reduced atmospheric oxygen pressure, pulmonary fibrosis or tumors and cardiac anomalies, and to local interference with the blood supply to the marrow by arteriolosclerosis in this tissue. These observations support the concept that an imbalance of the vasomotor mechanism produced by a disturbance of the equilibrium of the depressor action of the carotid sinus and cardioaortic proprioceptive nerves and the pressor action of the sympathetic system may be responsible for the development of erythremia. Paravertebral sympathectomy would thus represent a logical therapeutic measure. The observations of Schafer are sufficiently well founded to warrant additional study of these problems.

PENICILLIN ADJUVANT IN VIRUS RESEARCH

In 1942 Hirst[1] of the International Health Division, Rockefeller Foundation, developed a method for the isolation of human influenza virus by direct inoculation of mouth washings into 13 day old chick embryos. The mouth washings were first passed through a collodion membrane so as to remove bacterial contaminations. Hirst found that so much of the virus is lost by collodion filtration as often to render the filtrate noninfectious. Rose and his associates[2] of Columbia University therefore tried to render filtration unnecessary by the use of chemical antiseptics. Preliminary experiments showed that most of the available antiseptics when used in concentrations that would prevent bacterial growth were either lethal for the chick embryo or would interfere with the development of the accompanying virus.

In order to find a more favorable antibiotic, Rose tested the bactericidal or bacteriostatic effects of penicillin when added to sputum. Fifty-five specimens of sputum from patients with respiratory tract infections were selected for this test. Fifty-three of them had bronchitis or pneumonia of bacterial etiology. Two patients had severe gingivostomatitis. The 55 specimens were thoroughly emulsified in an equal volume of nutrient broth followed by low speed centrifugation. The supernatant fluid from each specimen was then divided into 2 parts; to 1 of these 500-1,000 Oxford units of penicillin per cubic centimeter was added.

Forty-nine of the 55 chick embryos inoculated with the untreated supernatant fluid died as a result of bacterial contamination, while 47 of the embryos inoculated with sputum plus penicillin survived. All of the surviving embryos were found to be bacteriologically sterile. Herpes virus was isolated on first passage from embryos inoculated with penicillin-treated sputum from the 2 cases of gingivostomatitis. All eggs inoculated with untreated sputum from the same cases died within twenty-four hours, with failure to recover the virus.

By use of a similar technic Hirst[3] had previously reported 33 successful isolations of influenza virus from throat washings from 33 influenza patients. Untreated throat washings from the same patients led to only 17 positive isolations. Parallel inoculations of ferrets led to 30 positive immune responses. From these differences Hirst concluded that inoculations of the amniotic sac of chick embryos with penicillin (25 Oxford units per cubic centimeter) plus throat washings is the most effective of present day methods for the isolation of influenza virus.

Use of penicillin in the isolation of viruses other than influenza and herpes has not yet been reported.

Current Comment

NO NEW MEDICAL DIRECTORY UNTIL 1947

Numerous inquiries are being received concerning the publication of a new edition of the American Medical Directory. Orders for the next (eighteenth) edition are not being accepted at this time; copies of the latest edition, published in 1942, are no longer available. One of the current problems in the Directory Department is the difficulty of keeping the records up to date regarding the relocations of the thousands of physicians being released from military service. Principally through the cooperation of the physicians themselves, the secretaries of county and state medical societies and the governmental agencies, considerable information is being received. About 20 per cent of the physicians are returning to their former office addresses or are obtaining new locations for practice, but the majority will first take refresher courses or serve residencies in hospitals. Every effort, nevertheless, is being made to obtain current information regarding all returning medical officers. Another problem that will delay the Directory is the shortage of necessary clerical help in our office and printing departments. Under ordinary circumstances, compilation and printing of a Directory require about twelve months. At present, however, it is doubtful whether a new Directory will be completed and ready for sale before the autumn of 1947. Medical officers particularly who read this comment and have not already notified the American Medical Association of their present location and status should do so at once, so that they may be correctly listed in the biographic files.

PENICILLIN THERAPY

The Pneumonia Technical Advisory Committee to the New York City Department of Health prepared a statement on the use of penicillin for distribution to physicians. Offered when the shortage of penicillin was at its peak, this statement was intended to cut waste of the drug so that more would be available to meet the rise in the incidence of respiratory disease. The committee warned against the use of penicillin for the prophylaxis and treatment of diseases for which it is obviously not intended, the continued treatment of patients long after any effective therapeutic benefit might be expected, and the use of oral preparations which require from three to six times the parenteral dosage and which are absorbed uncertainly from the gastrointestinal tract.

PROCUREMENT AND ASSIGNMENT QUOTAS APPLIED TO PHYSICIAN VETERANS

In its recent release on "Reconversion of the 9-9-9 Program" (The Journal, Nov. 24, 1945, p. 878) the relationship of physician veterans applying for residencies to the hospital house officer quotas assigned by the Procurement and Assignment Service was not entirely clear. Elsewhere in this issue there appears a statement by the Procurement and Assignment Service clarifying this matter. Veterans may be appointed to hospital residencies in excess of the quota of the hospital. They may remain outside the quota until they have become sufficiently trained to replace residents in that hospital who hold reserve commissions and are therefore eligible for active duty. Hospitals should attempt in this way to replace all residents holding commissions. At the time such replacement is complete the quota of that hospital will no longer be in effect. It should be emphasized again that physician veterans serving as residents need not be counted in hospital quotas initially. The Procurement and Assignment Service further announces that all quotas will be withdrawn from all hospitals on April 1, 1946.

A NEW ABSORBABLE SURGICAL DRESSING

A new absorbable material for use in neurologic surgery, suggested by Spitz and his associates,[1] is a casein fiber prepared from cow's milk and available under the trade name "Aralac." It is plentiful, inexpensive and uniform chemically. Aralac is readily spun into thread, forms an easily manipulated batting and can be repeatedly steam sterilized and stored indefinitely without deterioration. Pledgets of Aralac batting were inserted into the subcutaneous tissues, temporal muscle, subdural and subarachnoid spaces and the substance of the brain of a series of cats. None of the animals showed any ill effects from insertion of the casein fiber. Each was in good health at the termination of the experiment eleven to forty-six days later. At postmortem casein fiber was not visible grossly in any of the specimens. Microscopically small amounts of the fiber remained in 3 animals killed on or before the twelfth day. In cats which were allowed to survive twenty-three days or longer no trace of fiber remained. A few giant cells were found in the eleven day cats. At later stages the local reaction consisted chiefly of a slight fibrous tissue proliferation at or near the site of implantation. There was no evidence in any specimen that the casein fiber itself or any of its breakdown products was toxic to the cortical cells. The results therefore were as favorable as those previously reported from implantations of fibrin foam [2] or oxidized cotton.[3] More extensive studies of the absorbability of various types of plasticized sheets of casein are now in progress, with particular attention to the possibility of antibody formation. If bovine Aralac should prove to have undesirable antigenic properties, it is planned to try casein fiber from human milk.

MEDICINE AND THE WAR

Acc. No.
MEDICAL COLLEGE

MEDICAL SERVICE FOR VETERANS

ADDRESS BY COLONEL J. C. HARDING, DIRECTOR, OUTPATIENT SERVICE, VETERANS ADMINISTRATION, BEFORE THE CONFERENCE OF SECRETARIES AND EDITORS OF JOURNALS OF MEDICAL ASSOCIATIONS, CHICAGO, FRIDAY, FEBRUARY 8

Speaking as General Hawley's representative, I shall discuss some of the features of the medical program of the Veterans Administration, particularly as it relates to outpatient treatment and the securing of examinations for compensation and pension purposes. I should like to present to you some idea of the problems with which we are confronted and how we hope to solve those problems.

General Bradley, Administrator of Veterans Affairs, and General Hawley have gone on record many times to the effect that they are determined to provide for veterans the very best type of medical service obtainable. They realize that it was the complete cooperation of the civilian doctor, fitted into his proper sphere of interest and ability in the Army, that made our service to the G. I. outstanding in the field of military medicine and surgery. It is planned that this type of service will be continued in the Veterans Administration. The only difference will be that neither the doctor nor the patient will be in uniform.

As one means of accomplishing this, veterans' hospitals will be established in the vicinity of large medical centers. In this way we shall be able to obtain the services of leading members of the medical profession on a consultant basis. Arrangements already have been made with a number of medical schools which are located near Veterans Administration hospitals to utilize their faculties to augment and to improve the staffs at our veterans' hospitals.

Seventy-six of our existing ninety-seven veterans' hospitals are affected by this plan. Sixty of the seventy-five approved medical colleges in the country have expressed a desire to cooperate with the Veterans Administration in establishing high grade professional services in our veterans' hospitals. This can be accomplished, as far as consultants are concerned, by putting the consultants on a basis which will allow them to devote part of their time to veterans' hospitals in addition to engaging in private practice and teaching.

The medical colleges entering into this plan are requested to appoint a "Dean's Committee" to pass upon the qualifications for appointment of senior consultants, consultants or attending physicians and surgeons and ward officer residents.

Senior consultants now exist in most veterans' hospitals near medical centers. They are appointed from prominent men of the various specialties, and they act as supervisory consultants to the manager and the staff of the hospital. They will guide the teaching as well as the clinical service in the hospital.

Consultants or attending physicians or surgeons will be selected from discharged medical officers who are of a caliber to have held teaching positions in medical schools prior to their military service. They should be specialists certified by one of the examining boards. If they have not passed the second half of their board examination because of the entrance into military service, they may be recommended by the Dean's Committee on the basis of their past record. Consultants will be paid on a per visit basis. No two visits may be charged on the same day, and their compensation will not exceed $6,000, or an average monthly basis of $500. Their duties will be those expected of an attending physician in any university hospital.

Ward officer residents are to be selected at present from the ranks of discharged medical officers, whenever possible, by application to the Dean's Committee.

Men who have no credit toward board certification will be placed, on a rotating service, through all the subspecialties of medicine and surgery.

After their first complete rotation they will be allowed, wherever possible, to specify their preference as to a subspecialty. In veterans' hospitals these services can run as long as five years, one year of which will be in instruction in the basic sciences. Teaching institutions with which the veterans' hospitals are cooperating will be responsible for furnishing instruction in the basic sciences prescribed by various boards.

For many doctors who are in an older group and who have been in military service, credit will be given by the boards for certain work performed before and during the war.

MEDICAL SERVICES TO WHICH VETERANS ARE ENTITLED

While the plan which I have just sketched so briefly will raise the standards of treatment in veterans' hospital and will doubtless attract a considerable number of well qualified young physicians, it will not meet the immediate needs of the Veterans Administration in providing all the medical services to which veterans are entitled. At this time I will describe those services at a little greater length.

First, under existing law veterans who are not discharged from service under dishonorable conditions are entitled to hospital care in veterans' hospitals and other government hospitals with which the Veterans Administration has an agreement for the treatment of any disease or injury for which hospital care is indicated. Veterans in need of treatment for non-service connected disabilities are required to make a sworn statement that they are unable to defray their own hospital expenses.

Second, male veterans may also be hospitalized in private or contract hospitals for the treatment of service connected disabilities if government facilities are not available or their physical condition precludes travel to a veterans' hospital.

Third, female veterans, in addition to entitlement to hospital care in veterans' hospitals, may be admitted to private or contract hospitals, both for service connected and non-service connected conditions, if government facilities are not readily available.

THREE MAJOR PROBLEMS

The Veterans Administration, as far as the Office of the Chief Medical Director is concerned, is faced with three major problems. Problem number one is lack of professional personnel. Problem number two is lack of hospital beds. Problem number three is our tremendous outpatient examination and treatment load. A few figures will make the picture clear. At the present time the Veterans Administration has approximately 2,100 physicians on duty and there is a shortage of an equal number to take care of the present load. It is estimated that we should have at least 5,000 physicians to take care of the work in 1947.

The Veterans Administration is operating ninety-seven hospitals and, in addition, has in excess of 8,000 patients hospitalized in other government or civilian hospitals.

As of Jan. 24, 1946 there were over 72,000 patients in veterans' hospitals, of whom 48,000 were receiving hospital care for non-service connected disabilities.

The standard bed capacity of veterans' hospitals is in the neighborhood of 72,000 beds. Authorization has been received to increase this capacity by approximately 50,000 beds, of which 10,000 are now under construction. We also anticipate securing approximately 20,000 beds in army and navy hospitals.

In addition to our own building program, it is the hope of the Veterans Administration that arrangements may be made whereby private hospitals throughout the United States will hospitalize a larger number, perhaps 20,000 veterans, in their own hospitals on a contractual basis.

Many administrative problems will have to be solved so that hospitals will receive prompt and adequate reimbursement for the care which they give our patients. There is no doubt, however, that some sort of satisfactory formula can be worked out. We all realize that the operating costs of hospitals vary, sometimes to a large extent, even though the general service is approximately the same.

OUTPATIENT EXAMINATION AND TREATMENT LOAD

I have spoken of the three major problems in the Veterans Administration. I said that problem number three was our tremendous examination and treatment load of outpatients. As director of the outpatient service, I should like to give an idea of the magnitude of the work involved as well as the nature of some of the problems with which we are confronted. Under existing law a veteran is entitled to outpatient treatment for any disease or injury which was incurred in line of duty and which resulted in his discharge from service, and for the relief of any disease or injury which has been adjudicated as incurred in or aggravated by service.

During the year 1945 over 800,000 treatments were rendered on an outpatient basis; 593,000 of these treatments were rendered to veterans of World War I and 214,000 to veterans of World War II. When it is realized that there will be over 12 million veterans of World War II out of service by June 1946, the amount of work involved in handling the outpatient load alone can be readily appreciated.

In addition to rendering outpatient treatment, the outpatient service is responsible for conducting examinations of veterans filing claims for pension purposes. It is estimated that for the fiscal year 1947 2,121,000 veterans will require examinations for pension purposes. To meet this load, in addition to conducting examinations for other than pension purposes such as examinations to determine the need for hospital care, examinations for insurance purposes and civil service retirement it is estimated that we shall require the service of more than 3,000 full time physicians. It is self evident that this number of physicians will not be available. Consequently the Veterans Administration must rely on the medical profession throughout the country to help us in meeting our obligations to returned ex-service men and women. The medical profession has responded splendidly to General Hawley's appeal in this respect.

For a number of years the Veterans Administration has utilized the services of civilian physicians on a fee basis in conducting examinations for pension and compensation purposes and in rendering outpatient treatments for service connected disabilities. It has been realized for some time that the schedule of fees under which we were operating was inadequate, as it had not been revised for a number of years. Shortly after General Hawley assumed charge of the medical department I suggested that he appoint a committee to study and revise the fee schedule. The General felt, however, that he did not wish to establish any fixed schedule of fees on a national scale but rather to pay fees agreed on with various medical societies which were considered fair and equitable in the communities concerned. In accordance with this policy an agreement was reached with the District of Columbia Medical Society as to the fees to be paid in Washington for examinations, including those of the various specialties, for compensation and pension purposes. About this time, that is in October 1945, representatives of the Monmouth County of New Jersey Medical Society attended a conference in General Hawley's office, at which time an agreement was reached for the care of veterans in Monmouth County. The Monmouth County Plan was placed on a trial basis for a period of ninety days, at the end of which time recommendations were made by the society as to what action should be taken in ironing out the problems and difficulties encountered.

The chief problem encountered by the Monmouth Medical Society in rendering prompt and adequate service to veterans was the delay on the part of the Veterans Administration in making a determination as to the entitlement of veterans to treatment on an outpatient basis. For instance, out of 226 veterans reporting to the Monmouth County clinics during the period from Nov. 9, 1945 to Jan. 25, 1946, definite action had been taken by the Veterans Administration on only 102 cases. This falls far short of the goal which we hoped to attain.

As I stated previously, a veteran is entitled to outpatient treatment for any condition which was incurred in line of duty and which resulted in his discharge from service or for the treatment of any condition which subsequent to his discharge has been adjudicated as incurred in or aggravated by service. Veterans medically surveyed from service because of disability incurred in line of duty do not present any problem, as their claims can be adjudicated on the basis of the medical or hospital report within a short time. However, veterans who have been discharged from service on points and who subsequently apply for outpatient treatment have been required in many instances to wait several weeks or even months before a determination was made as to their entitlement to outpatient treatment. I feel sure that we finally have overcome this major problem, which has been the cause of justifiable criticism throughout the whole country. On the basis of an opinion obtained from our solicitor, a directive has been released within the past few days which permits chief medical officers and their designates to make a tentative determination that the condition for which the veteran is requesting treatment is in all probability due to service on the basis of prima facie evidence, including any service records available and the veteran's sworn statement as to the origin and history of the condition for which he is requesting treatment. Under this directive, chief medical officers and their designates can thus authorize outpatient treatment and emergency hospitalization in private or contract hospitals if in their opinion there is a reasonable probability that the veteran's disability was incurred in or aggravated by service.

While the Monmouth County Plan has been working very satisfactorily, it can readily be appreciated that as there are over three thousand counties in the United States it would be far better, from an administrative standpoint, to work out agreements with state medical societies which would be applicable throughout the entire number of states concerned. We have accordingly made agreements with the Kansas State Medical Society, with the Michigan State Medical Society and the Michigan Medical Service of Detroit, the California Physicians Service of San Francisco and the Medical Service Administration of New Jersey for the furnishing of medical services to veterans. We have also had contacts with many other state medical soceties, including those of Massachusetts, New York, Pennsylvania, West Virginia, North Carolina, Illinois, Missouri and Colorado. As the Kansas plan differs materially from the plans of Michigan, California and New Jersey, it should be of interest to become acquainted with its provisions as well as the law of Michigan, which is practically identical to the plans of California and New Jersey.

The Kansas plan reads as follows:

1. The Kansas State Medical Society will submit a list of its members who desire to do work for the Veterans Administration in accordance with the schedule of fees (approved by the Veterans Administration) in relation to examinations, office, outpatient care and hospital care.

2. The Kansas State Medical Society will furnish to the Veterans Administration a list of the physicians who are competent to do such work in their respective fields. On the basis of these lists, which will be submitted to the manager of the Wichita Veterans Center and which will be augmented from

time to time, members of the society will be appointed as fee designated Veterans Administration physicians.

3. The Kansas State Medical Society proposes to zone the state in order that the nearest qualified physician may be called upon to render the medical service.

4. The Veterans Administration will establish an office adjacent to the office of the Kansas State Medical Society in Topeka, which office will be staffed with a full time or part time Veterans Administration physician and adequate clerical personnel to handle the administrative work. It will be the function of the Veterans Administration physician to authorize outpatient examination and treatments (inpatient and outpatient) and to arrange for the necessary transportation of the veteran. The Veterans Administration physician will review reports of examinations and reports of treatments rendered to determine their adequacy and will return those deemed inadequate to a board of physicians appointed by the Kansas State Medical Society for indicated action. No fees will be paid for examinations or reports which are not acceptable to the Veterans Administration. It shall be the duty of the board appointed by the Kansas State Medical Society to recommend the disqualification of any physician from further work with the Veterans Administration whose work is incomplete or unsatisfactory at the discretion of the board.

5. The Kansas State Medical Society does not propose to make any charge for any service rendered to the Veterans Administration in connection with the supervision of the work performed by its members. It is the purpose of the Kansas State Medical Society in collaboration with the Veterans Administration to render the best possible medical service to veterans in the state of Kansas.

The Michigan contract reads as follows:

1. The Michigan Medical Service will arrange, through physicians registered with it for the rendition of the medical services covered by this agreement, for examinations, treatments and counsel in such cases as may be authorized by the Veterans Administration, Michigan Medical Service reserving the right, however, to decline any particular case.

2. The Veterans Administration will authorize examinations, treatments and counsel. Authorizations for such services will be issued to the Michigan Medical Service; the Michigan Medical Service will advise the veteran to report to a physician of the veteran's selection in his community, such selection to be limited to those physicians registered with Michigan Medical Service for the rendition of services under this agreement.

3. The Michigan Medical Service will be responsible for seeing that reports required by the Veterans Administration are in proper form and that proper records are maintained which will be available for review by the Veterans Administration at any time. The Veterans Administration will review reports of services and will return to Michigan Medical Service for further action, without additional cost to the Veterans Administration, those which do not meet the requirements of the Veterans Administration.

4. Fees for medical services will be in accordance with the fee schedule, which is attached and made a part of the contract. It is understood that unusually involved cases and services not scheduled will be subject to review and recommendation by Michigan Medical Service to the Veterans Administration for determination of appropriate fee.

5. The Michigan Medical Service will make payment to the individual physicians for services rendered in all cases in which authorizations have been issued and will in turn bill the Veterans Administration at the end of each month. The Veterans Administration will remit in accordance with such bill within a reasonable time after receipt thereof.

6. The Michigan Medical Service contemplates that the performance of this contract will be without profit to it, and, if operating results are at variance with this intention, revisions will be proposed to produce such a nonprofit operation.

It will be noted that the essential difference in the plans of Kansas and Michigan is that, in Kansas, members of the Kansas State Medical Society will be appointed as fee designated physicians and the Veterans Administration will pay the physicians direct for services rendered, whereas under the Michigan plan the physicians will be paid by Michigan Medical Service, and they in turn will bill the Veterans Administration at rates in accordance with the schedule of fees agreed on.

As the Michigan Medical Service contract was the first of its kind to be negotiated, certain legal difficulties arose which required considerable time to straighten out. I feel sure that the contract is workable and that it will go a long way toward solving our problem in furnishing outpatient medical service to veterans. I should like to see a plan similar to it placed into effect in as many other states as possible.

Under this contract the veteran is permitted, with some limitations, to select his own physician. It is believed that this will have a good psychologic effect on the veteran in that he will have more confidence in the physician he selects to treat his case than he would in a physician to whom he might be ordered to report for examination or treatment and who, in all probability, would be a total stranger to him.

While certain problems and difficulties will no doubt arise in the administration of this plan or any other plans which we may adopt, I am certain that, with the cooperation already manifested by the various medical societies these problems can be overcome.

It is only through cooperation of this sort that the goal in which we are all interested can most quickly be reached. That goal is to provide for sick or disabled veterans the very best medical treatment and care and the most up to date medical service that it is possible to obtain.

VETERANS

CONSULTANTS NAMED FOR VETERANS' HOSPITALS

Eleven physicians were recently appointed to serve as consultants to the veterans' hospitals by Major Gen. Paul R. Hawley, Acting Surgeon General of the Veterans Administration.

Brig. Gen. Elliott C. Cutler, professor of surgery, Harvard Medical School, and also attached to the Peter Bent Brigham Hospital, Boston, headed the list. Other consultants are:

Lieut. Col. Brian B. Blades, Washington, D. C., chest surgery.

Col. Barrett Brown, Phoenixville, Pa., plastic surgery.

Dr. Trygve Gunderson, Brookline, Mass., diseases of the eye.

Lieut. Col. Aubrey Hampton, Washington, D. C., formerly of Harvard Medical School, Boston, radiology.

Dr. Bernard J. Pisani, New York, gynecology.

Dr. Donald M. Pillsbury, Philadelphia, assistant professor at the Jefferson Medical College and University of Pennsylvania School of Medicine, Philadelphia, skin diseases.

Dr. John N. Robinson, Sharon, Conn., urology.

Col. Roy Glenwood Spurling, Washington, D. C., neurosurgery.

Dr. Ralph Tovell, Hartford, Conn., anesthesiology.

Dr. Robert M. Zolliner, Boston, assistant professor, Harvard Medical School, general surgery.

Consultants now attached with the Army's Medical Corps will serve without pay until they have been released from active duty.

APPOINTMENT AS CONSULTANT FOR MEDICAL CARE OF WOMEN VETERANS

Lieut. Col. Margaret D. Craighill, Philadelphia, was recently appointed consultant for the medical care of women veterans. She is on leave from the Women's Medical College of Pennsylvania in Philadelphia, where she was dean. Dr. Craighill graduated from Johns Hopkins University School of Medicine, Baltimore, in 1924 and entered the service May 28, 1943.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

RECONVERSION OF 9-9-9 PROGRAM

Inquiries about paragraph 3 of section III of directive number 382 (Nov. 6, 1945), relating to the circumstances under which hospitals may exceed quotas, have prompted the following further explanation:

Veterans should be accepted for residencies in hospitals without being counted in the resident quota until they are sufficiently trained to replace a commissioned officer satisfactorily. When a veteran is sufficiently trained to replace a commissioned officer, the officer should be released for active duty at once and at that time the veteran on duty should be counted in the quota. When an institution has thus replaced its last commissioned officer, all quota restrictions are withdrawn as to that institution.

For example, if a hospital has a quota of twelve residencies, six of which are filled by commissioned officers and six of which are filled by women or men who are ineligible for military service, and six veterans beyond the quota, it is expected that, when one of the veterans becomes sufficiently trained so that he can assume the duties of assistant resident in medicine (and there is a commissioned officer filling a position as assistant resident in medicine), the commissioned officer should be released for active duty and the veteran counted in the quota at that time. The hospital will then have five veterans who are not counted in the quota and twelve residents who are counted in the quota, five of whom will still be commissioned officers. This replacement program should continue as rapidly as possible between now and April 1, 1946 until the last commissioned officer has been replaced, at which time the hospital is no longer under any quota regulations.

It should be obvious to every hospital superintendent and medical director that the quicker he makes use of such veterans the more stable will be his staff and the sooner he can return to his peacetime resident program.

PROCUREMENT AND ASSIGNMENT SERVICE RESIDENT QUOTAS

The Procurement and Assignment Service will withdraw the resident quota restrictions on each hospital on the date on which that hospital releases its last commissioned resident and will withdraw all quotas from other hospitals on April 1, 1946.

PROCUREMENT AND ASSIGNMENT SERVICE INTERN QUOTAS

No hospital should accept for internships beginning April 1, 1946 more interns from the senior class graduating in March 1946 than their present intern quota. This rule holds for those hospitals which have 100 per cent of their interns on a July to April term. If the hospital has interns who started their internships after July 1, 1945 they should discount them from their quota and fill the remainder of their quota with March graduates. After April 1, 1946 Procurement and Assignment Service intern quotas may be disregarded.

ARMY

ARMY AWARDS AND COMMENDATIONS

Colonel Howard A. Rusk

The Distinguished Service Medal was recently awarded to Col. Howard A. Rusk, formerly of St. Louis. The citation accompanying the award states that "Col. Howard A. Rush, Medical Corps, from March 1943 to October 1945 bore the heavy responsibilities of chief of convalescent and rehabilitation branch, Professional Services Division, and chief of the convalescent services division, Office of the Air Surgeon, Given the difficult assignment of pioneering the organization of a convalescent services program in each Army Air Forces hospital, he instituted procedures for physical reconditioning and educational training which utilized previously wasted convalescent time. The results of this far reaching program were extraordinarily successful. Hospital readmissions dwindled, the period of convalescence was shortened, sick leaves were reduced, the military and general knowledge and skills of the patients was increased and tremendous improvement of morale in the hospitalized men was noted. The outgrowth of Colonel Rusk's program was the Air Forces plan for the rehabilitation and convalescent care for returning overseas casualties. Through great vision, superior organizational ability and wide experience gained in the practical application of his theories, Colonel Rusk accomplished a task which benefited thousands of soldiers and contributed in important measure to the success of the Army Air Forces' vast medical program." Dr. Rusk graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1925 and entered the service Aug. 18, 1942.

Brigadier General Henry C. Dooling

The Legion of Merit was recently presented to Brig. Gen. Henry C. Dooling, surgeon, Caribbean Defense Command and chief health officer, Panama Canal. The citation accompanying the award said, in part, "Despite greatly increased difficulties due to the growth of population, troop concentrations, the passage of large contingents of military forces through the canal and wartime conditions affecting supply, he maintained high health standards. By his great professional skill, tireless energy and sound judgment General Dooling contributed in important measure to the successful performance of the Panama Canal's war mission." Dr. Dooling graduated from the Medico-Chirurgical College of Philadelphia in 1908 and entered the service Sept. 18, 1917.

MEDICAL ACTIVITIES MOVED TO FORT SAM HOUSTON

Major Gen. Norman T. Kirk, Surgeon General of the Army, recently announced that a move involving approximately 6,000 enlisted men and officers will be completed by March 15, when medical activities of Carlisle Barracks, Pa., and the Medical Section and certain portions of the basic training program at the Army Service Forces Training Center, Fort Lewis, Washington, will be transferred to Fort Sam Houston, Texas.

The concentration of the medical department schools and courses at this new center will represent a saving in the transportation of trainees from one school to another in many cases and also will result in more economical and effective operation of the training program, according to Col. Floyd L. Wergeland, director of the Education and Training Division of the Surgeon General's Office.

Plans are being made for five battalions which will train about 5,000 men in basic and technician courses at Fort Sam Houston. A basic medical department officers' course of approximately 1,100 newly commissioned officers will be in continuous operation, Colonel Wergeland said.

The basic training will require six weeks and the basic technicians' course will take another seven weeks, making a total of thirteen weeks. The technician schools include courses of eight to sixteen weeks for dental, laboratory, x-ray, surgical and medical technicians. There will be common specialist courses for cooks and bakers, chauffeurs, clerks, auto mechanics and sanitary technicians.

There will be a School of Military Neuropsychiatry and a School of Roentgenology and Medical Equipment Maintenance Technician courses. Residency type training for Medical Corps officers will be carried on at Brooke General Hospital, Fort Sam Houston, and also at nine other general hospitals in this country as part of the Surgeon General's plan to provide greater opportunities for professional advancement to the members of the Army Medical Corps.

the entire rent may be deducted. If he rents a building or apartment for use as a residence as well as for office purposes, he may deduct a part of the rental fairly proportionate to the amount of space used for professional purposes. If the physician occasionally sees a patient in such dwelling house or apartment, he may not, however, deduct any part of the rent of such house or apartment as professional expense; to entitle him to such a deduction he must have an office there, with regular office hours. If a physician owns the building in which his office is located, he cannot charge himself with "rent" and deduct the amount so charged.

Office Maintenance.—Expenditures for office maintenance, as for heating, lighting, telephone service and the services of attendants, are deductible.

Supplies.—Payments for supplies for professional use are deductible. Supplies may be fairly described as articles consumed in the using; for instance, dressings, clinical thermometers, drugs and chemicals. Professional journals may be classified as supplies and the subscription price deducted. Amounts currently expended for books, furniture and professional instruments and equipment, "the useful life of which is short," generally less than one year, may be deducted, but if such articles have a more or less permanent value, their purchase price is a capital expenditure and is not deductible.

Equipment.—Equipment comprises property of a more or less permanent nature. It may ultimately wear out, deteriorate or become obsolete, but it is not in the ordinary sense of the word "consumed in the using."

The cost of equipment such as has been described, for professional use, cannot be deducted as expense in the year acquired. Examples of this class of property are automobiles, office furniture, medical, surgical and laboratory equipment of more or less permanent nature, and instruments and appliances constituting a part of the physician's professional outfit, to be used over a considerable period of time, generally over one year. Books of more or less permanent nature are regarded as equipment and the purchase price is therefore not deductible.

Although the cost of such equipment is not deductible in the year acquired, nevertheless it may be recovered through depreciation deductions taken year by year over its useful life, as described later.

No hard and fast rule can be laid down as to what part of the cost of equipment is deductible each year as depreciation. The amount depends to some extent on the nature of the property and on the extent and character of its use. The length of its useful life should be the primary consideration. The most that can be done is to suggest certain average or normal rates of depreciation for each of several classes of articles and to leave to the taxpayer the modification of the suggested rates as the circumstances of his particular case may dictate. As fair, normal or average rates of depreciation, the following have been suggested: automobiles, 25 per cent a year; ordinary medical libraries, x-ray equipment, physical therapy equipment, electrical sterilizers, surgical instruments and diagnostic apparatus, 10 per cent a year; office furniture, 5 per cent a year.

The principle governing the determination of all rates of depreciation is that the total amount claimed by the taxpayer as depreciation during the life of the article, plus the salvage value of the article at the end of its useful life, shall not be greater than its purchase price. The physician must in good faith use his best judgment and claim only such allowance for depreciation as the facts justify. The estimate of useful life, on which the rate of depreciation is based, should be carefully considered in each individual case.

Medical Dues.—Dues paid to societies of a strictly professional character are deductible. Dues paid to social organizations, even though their membership is limited to physicians, are personal expenses and not deductible.

Postgraduate Study.—The Commissioner of Internal Revenue holds that the expense of postgraduate study is not deductible.

Traveling Expenses.—Traveling expenses, including amounts paid for transportation, meals and lodging, necessarily incurred in professional visits to patients and in attending medical meetings for a professional purpose, are deductible.

Automobiles.—Payment for an automobile is a payment for permanent equipment and is not deductible. The cost of operation and repair, and loss through depreciation, are deductible. The cost of operation and repair includes the cost of gasoline, oil, tires, insurance, repairs, garage rental (when the garage is not owned by the physician), chauffeur's wages, and the like.

Deductible loss through depreciation of an automobile is the actual diminution in value resulting from obsolescence and use and from accidental injury against which the physician is not insured. If depreciation is computed on the basis of the average loss during a series of years, the series must extend over the entire estimated life of the car, not merely over the period in which the car is possessed by the present taxpayer.

If an automobile is used for professional and also for personal purposes—as when used by the physician partly for recreation, or so used by his family—only so much of the expense as arises out of the use for professional purposes may be deducted. A physician doing an exclusive office practice and using his car merely to go to and from his office cannot deduct depreciation or operating expenses; he is regarded as using his car for his personal convenience and not as a means of gaining a livelihood. What has been said in respect to automobiles applies with equal force to horses and vehicles and the equipment incident to their use.

MISCELLANEOUS

Contributions to Charitable Organizations.—For detailed information with respect to the deductibility of charitable contributions generally, physicians should consult the official return blank or obtain information from the collectors of internal revenue or from other reliable sources. Attention is called to the change in the law that applies to deductions for charitable contributions, namely, that an individual taxpayer can deduct such contributions only to the extent that they do not exceed 15 per cent of his adjusted gross income. The physician may not deduct as a charitable contribution the value of services rendered an organization operated for charitable purposes.

Bad Debts.—Physicians who make their returns on a cash receipts and disbursements basis, as most physicians do, cannot claim deductions for bad debts.

Taxes.—Taxes generally, either federal or state, are deductible by the person on whom they are imposed by law. Both real and personal property taxes are deductible; but so-called taxes, more properly assessments, paid for local benefits, such as street, sidewalk and other like improvements, imposed because of and measured by some benefit inuring directly to the property against which the assessment is levied, do not constitute an allowable deduction from gross income. Physicians may deduct state gasoline taxes and state sales taxes. In some states sales taxes are imposed on the seller, but, if they are passed on to the buyer, the latter may deduct them.

State income and use taxes are deductible; federal income taxes are not. Federal import, excise or stamp taxes are deductible only to the extent that they are attributable to business activities. State automobile license fees are deductible. If a state or local fee is imposed for regulatory purposes, and not to raise revenue, the fee may not ordinarily be deducted as a tax. If such fees, however, are classifiable as a business expense, they are deductible as such. Annual registration fees imposed on physicians probably come within the category of regulatory fees and should be deducted as a business expense rather than as taxes. Local and state occupational taxes imposed on physicians are deductible either as taxes or as a business expense, depending on the purpose for which the tax is imposed.

The excise taxes imposed on employers by section 804, title VIII, and section 901, title IX, of the Social Security Act, commonly referred to as old age and unemployment benefit taxes, are deductible annually by employers in computing net income for federal income tax purposes. If the taxpayer's return is made on a cash basis, as are the returns of practically all physicians, the taxes are deductible for the year in which they are actually paid. If the return is made on an accrual basis, the taxes are deductible for the year in which they accrue, irrespective of when they are actually paid. Employees, including physicians whose employment brings them within that category, may not deduct the tax imposed on them by section 801, title VIII, of the Social Security Act, generally referred to as the old age benefits tax. If, however, the employer assumes payment of the employee's tax and does not withhold the amount of the tax from the employee's wages, the amount of the tax so assumed may be deducted by the employer, not as a tax paid but as an ordinary business expense.

Medical Expense.—A taxpayer may deduct amounts expended for medical, dental and hospital care for himself, his spouse or a dependent, not compensated for by insurance or otherwise, including amounts paid for accident and health insurance, according to a prescribed formula. Deductions will be permitted to the extent that such expenses exceed 5 per cent of the adjusted gross income of the taxpayer but not in excess of $2,500 in case of a taxpayer with more than one surtax exemption, or $1,250 in case of a taxpayer with only one surtax exemption.

Laboratory Expenses.—The deductibility of the expenses of establishing and maintaining laboratories is determined by the same principles that determine the deductibility of corresponding professional expenses. Laboratory rental and the expenses of laboratory equipment and supplies and of laboratory assistants are deductible when under corresponding circumstances they would be deductible if they related to a physician's office.

Losses by Fire or Other Causes.—Loss of and damage to a physician's equipment by fire, theft or other cause, not compensated by insurance or otherwise recoverable, may be computed as a business expense and is deductible, provided evidence of such loss or damage can be produced. Such loss or damage is deductible, however, only to the extent to which it has not been made good by repair and the cost of repair claimed as a deduction.

Insurance Premiums.—Premiums paid for insurance against professional losses are deductible. This includes insurance against damages for alleged malpractice, against liability for injuries by a physician's automobile while in use for professional purposes, and against loss from theft of professional equipment and damage to or loss of professional equipment by fire or otherwise. Under professional equipment is to be included any automobile belonging to the physician and used for strictly professional purposes.

Expense in Defending Malpractice Suits.—Expense incurred in the defense of a suit for malpractice is deductible as a business expense.

Sale of Spectacles.—Oculists who furnish spectacles, etc., may charge as income money received from such sales and deduct as an expense the cost of the article sold. Entries on the physician's account books should in such cases show charges for services separate and apart from charges for spectacles, etc.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Health Programs for Government Employees

The Senate Committee on Civil Service has reported H. R. 2716 to the Senate with the recommendation that it pass, providing health programs for government employees to be established in localities where there are a sufficient number of federal employees to warrant the provision of such services. Services will be limited to (1) treatments on the job of illnesses and dental conditions requiring emergency attention, (2) preemployment and other examinations, (3) referral of employees to private physicians and dentists and (4) preventive programs relating to health. An amendment proposed by the Senate committee would authorize the utilization of osteopathic services in the health programs to be established under the bill.

Educational Loans

Senator Langer, North Dakota, by S. 1782, proposes an appropriation of $3,000,000,000 to enable the Commissioner of Education to make loans to individuals desiring to obtain vocational, technical, academic or professional education beyond the high school level. The commissioner would be authorized to promulgate such rules and regulations as may be necessary to carry out the provisions of the legislation.

Chemical Tests for Intoxication

An amendment to the District of Columbia Traffic Act is proposed by H. R. 5406, introduced by Representative Hébert, Louisiana, by request, to provide tests of blood, urine and breath of persons arrested in the District of Columbia on a charge of operating a vehicle under the influence of intoxicating liquor or on a charge of negligent homicide or on a charge of manslaughter committed in the operation of any vehicle. The bill proposes that (1) evidence that there was five one-hundredths of 1 per cent, or less, by weight of alcohol in the defendant's blood or urine or an equivalent amount of alcohol in two thousand cubic centimeters of his breath (alveolar air), shall be prima facie evidence that the defendant was not under the influence of intoxicating liquor at the time the specimen was taken; (2) evidence that there was more than five one-hundredths of 1 per cent and less than fifteen one-hundredths of 1 per cent by weight of alcohol in the defendant's blood or urine, or an equivalent amount of alcohol in two thousand cubic centimeters of his breath (alveolar air), shall be relevant evidence but is not to be given prima facie effect in indicating whether or not the defendant was under the influence of intoxicating liquor at the time the specimen was taken; and (3) evidence that there was fifteen one-hundredths of 1 per cent, or more, by weight of alcohol in such defendant's blood or urine, or an equivalent amount of alcohol in two thousand cubic centimeters of his breath (alveolar air), shall be prima facie evidence that such defendant was under the influence of intoxicating liquor at the time the specimen was taken.

Hill-Burton Hospital Construction Bill

Hearings have been scheduled to begin on or about February 25 by a subcommittee of the House Committee on Interstate and Foreign Commerce on the Hill-Burton hospital construction bill.

STATE LEGISLATION

California

Bill Introduced.—S. C. R. 16-X proposes a resolution requesting the state director of finance to appropriate $44,000 for the purpose of carrying out a 1945 law providing for the better protection of the public health by state licensing, inspecting, regulating and supervising of public and private hospitals.

Bills Passed.—A. 37-X passed the senate January 31. It proposes to amend the business and professions code so as to increase the annual tax and registration fee of osteopaths from $5 to $10 for residents and from $2 to $10 for nonresidents. A. 88-X passed the assembly on January 22. It proposes the creation of a State Advisory Council on Hospital Facilities and would authorize the Department of Public Health to make a survey of existing public and private hospitals and health centers in the state, to evaluate the sufficiency of such hospitals and health centers to supply the necessary physical facilities for furnishing adequate hospital, clinic and similar services to the people of the state, and to make any recommendations concerning additional facilities as may be necessary. Prior to passage by the assembly, this proposal was amended to provide that the word "hospital" shall not include any institution conducted by or for the adherents of any well recognized church or religious denominations for the purpose of providing facilities for the care or treatment of the sick who depend on prayer or spiritual means for healing in the practice of the religion of such church or denomination.

Georgia

Bills Enacted.—H. 655 became Governor's Act 576 of the Acts of 1945 on January 31. It amends the law relating to qualifications of applicants for a license to practice nursing by reducing from 21 to 20 the required age of the applicant. H. 732 became chapter 623 of the Laws of 1946 on February 1. It authorizes the Board of Health to make and promulgate reasonable rules and regulations for the protection of the health and lives of inmates and patients of hospitals, sanatoriums, infirmaries, maternity homes, nursing homes and other institutions where persons are received for treatment, examination, maternity care or nursing care in the state. In connection therewith a hospital advisory committee will be established, consisting of three members appointed by the Medical Association of Georgia or its Board of Councilors, the total membership of the advisory committee numbering fourteen.

Kentucky

Bills Introduced.—H. 171 proposes the enactment of a law authorizing the establishment, maintenance and operation of medical service plan corporations. "Medical services" would mean the "general and usual services rendered and care administered by doctors of medicine." "Participating physician" would mean a "doctor of medicine licensed to practice medicine and surgery in this state under the provisions of the medical practice act" who agrees in writing to perform the services specified by the subscription certificates. S. 87 proposes that any person or corporation operating a hospital in Kentucky shall first obtain a license therefor. "Hospital" is defined as "any institution which maintains and operates organized facilities for the diagnosis, treatment and care of humans suffering from illness, injury or deformity, where bedside nursing care is rendered for a period exceeding twenty-four (24) hours."

Bill Passed.—S. 56 passed the senate January 31. To amend the law relating to the practice of pharmacy, this bill proposes that applicants for a license must be citizens of the United States, must have graduated from a school or college of pharmacy recognized and approved by the Kentucky board of pharmacy and must submit proper affidavits showing a minimum of one year of experience in a retail pharmacy under the supervision of a registered pharmacist.

Massachusetts

Bills Introduced.—H. 722 proposes that any clinic maintained by an insurance company for the treatment of injuries occasioned to employees of any of its assureds shall be open at all times for the reception of patients and shall have in attendance at all times a qualified physician.

Mississippi

Bills Introduced.—H. 235, to amend the law authorizing towns and districts to operate and maintain community hospitals, proposes that at least one member of the board of trustees of such institution shall be a practicing physician in good standing with the state medical association. H. 298, to amend the law relating to the issuance of marriage licenses, proposes that both applicants for a marriage license shall present a certificate certifying that he or she is "free from syphilis, gonorrhea and chancroid, or certifying as to the exact status of the venereal disease." The medical examination on which the certificate is based may be made by an active licensed physician in Mississippi, by a physician licensed to practice in any or all of the other states of the Union or the District of Columbia, by a commissioned medical officer on active duty in the armed forces of the United States, or by a medical officer of the United States Public Health Service, provided that said examination may be made free of charge by any full time county health officer licensed to practice in Mississippi if the person examined is unable to pay for same. H. 300 proposes to authorize the Mississippi State Board of Health to establish one hundred annual medical scholarships of the annual value of five hundred dollars each. The purpose of these scholarships is to induce medical graduates to engage in the general practice of medicine in a rural community in Mississippi.

Bill Enacted.—H. R. 10 was adopted Jan. 17, 1946. This is a resolution memorializing the Congress of the United States to enact suitable and adequate legislation for the training of doctors at government expense to take care of personnel of the United States armed forces wounded in the service of the country.

New York

Bills Introduced.—A. 610, to amend the public health law, proposes to require every physician to give notice immediately to the health officer of the county, city, town or village of every case of infantile paralysis under his care. Like notice would be given by the person in charge of any hospital, dispensary, asylum or other similar institution of every case of infantile paralysis coming under its care. The proposal also would create in the state department of health a division of infantile paralysis control. A. 683 and S. 577, to amend the workmen's compensation law, proposes that physician members of the advisory council shall not be eligible for authorization to render medical care under the workmen's compensation law and shall not examine, treat, consult or in any way care for a compensation claimant at the request either of the claimant or of a carrier. A. 706, to amend the unemployment insurance law, proposes that sickness or accident disability causing unemployment shall be certified under oath by a physician or surgeon duly licensed to practice in the state of New York. A. 730 proposes a licensing law for persons and institutions desiring to conduct scientific experiments or to perform vivisection on living dogs. A. 741 and S. 603, to amend the education law, propose the establishment of the New York state university to be composed of a college of arts and sciences, engineering, medicine, law and such other colleges and professional schools as the regents may from time to time establish. A. 823, to amend the law relating to experiments on living dogs, proposes to prohibit such experiments even though conducted under the authority of the faculty of some regularly incorporated medical college or university as at present permitted. A. 839, to amend the education law, proposes the establishment of an Empire State University, to include, among other things, a school of medicine. A. 854, to amend the workmen's compensation law, proposes that an injured employee requiring dental care may select any dentist to treat him who is authorized under rules and regulations adopted by the commissioner on the recommendation of the state board of dental examiners. The reasonableness and necessity for such dental care and treatment shall be determined by the industrial board. A. 862, to amend the workmen's compensation law, proposes that the physician members of any committee appointed by the chairman of the industrial board to assist him in any particular case shall receive a fee for each case or shall be paid on a per diem basis as determined by the chairman. If they make a report and testify, they shall be paid an additional fee. S. 556, to amend the law in relation to hospital liens, proposes that such liens shall not include personal services rendered by a physician or surgeon and that the rates charged by the hospital shall be deemed equivalent to the scheduled rates currently approved by the industrial commissioner and the superintendent of insurance for cases under the workmen's compensation law. S. 620, to amend the law relating to actions for damages for death caused by wrongful act and the distribution of the proceeds thereof, proposes to put in the first priority of items to be paid for when damages are distributed the reasonable expenses of medical aid, nursing and attention incident to the injury causing death. S. 659, to amend the law in relation to barbiturates, proposes to prohibit the sale at retail of any barbiturate or other hypnotic or somnifacient drug to any person except on prescription written by "a person legally authorized to issue such prescription." A prescription shall state whether or not it may be refilled.

Virginia

Bill Introduced.—S. 120 proposes to authorize the establishment within the Department of Health of a Bureau of Rabies Control to prevent the occurrence and spread of said disease.

Coming Medical Meetings

Aero Medical Association, Chicago, April 7-9. Dr. David S. Brachman, 1016 Dime Building, Detroit 26, Secretary.

American Association of Anatomists, Cleveland, April 4-6. Dr. Eliot R. Clark, University of Pennsylvania School of Medicine, Philadelphia 4, Secretary.

American Association of Pathologists and Bacteriologists, Chicago, March 8-9. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland, Secretary.

American Physiological Society, Atlantic City, March 11-15. Dr. Wallace O. Fenn, 260 Crittenden Blvd., Rochester 7, New York, Secretary.

American Society for Experimental Pathology, Atlantic City, March 11-15. Dr. Harry P. Smith, 630 W. 168th St., New York 32, Secretary.

American Society for Pharmacology and Experimental Therapeutics, Atlantic City, March 11-15. Dr. Raymond N. Bieter, University of Minnesota Medical School, Minneapolis, Secretary.

American Surgical Association, Hot Springs, Va., April 2-4. Dr. Warfield M. Firor, Johns Hopkins Hospital, Baltimore 5, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, March 5-8. Dr. Warren W. Furey, 30 North Michigan Ave., Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, March 18-21. Dr. John G. Young, 1719 Pacific Avenue, Dallas 1, Director of Clinics.

Federation of American Societies for Experimental Biology, Atlantic City, March 11-15. Dr. D. R. Hooker, 19 West Chase Street, Baltimore 1, Secretary.

Medical Library Association, New Haven, Conn., March 25-27. Miss Frida Pliefke, 2000 Medical Arts Bldg., Minneapolis 2, Secretary.

Missouri State Medical Association, St. Louis, March 24-26. Dr. Ralph L. Thompson, 634 N. Grand Blvd., St. Louis 3, Secretary.

Southeastern Surgical Congress, Memphis, Tenn., March 11-13. Dr. Benjamin T. Beasley, 45 Edgewood Ave. S.E., Atlanta 3, Georgia, Secretary.

Tennessee State Medical Association, Knoxville, April 9-11. Dr. W. M. Hardy, 706 Church Street, Nashville, Secretary.

Washington Letter

(From a Special Correspondent)

Feb. 11, 1946.

General Bradley Receives Backing of Medical Chiefs

Medical chiefs of the United States armed forces joined with President Truman in backing General Omar Bradley in his program of veteran hospitalization which has been criticized by John Stelle, national commander of the American Legion as indicative of a "tragic breakdown" in the Veterans Administration. Approving the plans of General Bradley and his medical director, Major Gen. Paul R. Hawley, were Major Gen. Norman T. Kirk, Surgeon General of the Army; Vice Admiral Ross T. McIntire, Surgeon General of the Navy; Major Gen. Warren Draper, Deputy Surgeon General of the Public Health Service, and Brig. Gen. Malcolm Grow, Surgeon General of the Army Air Forces. General Kirk pledged "complete support" to Bradley and Hawley, declaring "I think their plans are ideal. By setting up hospitals near large cities patients will be treated by the best specialists and Veterans Administration doctors will become better physicians." The only alternative, he said, was to build hospitals on the basis of "pork and patronage." Admiral McIntire pointed out that the Federal Bureau of Hospitalization supported the Bradley program. General Draper advocated "swamping" attacks on Bradley so that he can "go ahead and do a decent job for thousands of veterans." He urged the Veterans Administration chiefs to "stick to their guns." President Truman had pledged his "complete and unqualified support to General Bradley."

Antivivisectionists Seek Medical Testimony

Representative Lemke, Republican of North Dakota, states that he is seeking to have several nationally known doctors testify at forthcoming hearings on legislation to forbid experimentation on dogs in the District of Columbia. Sponsor of the bill which provides a minimum $100 fine, three months in prison or both for violations, he said that he felt such medical testimony would help to offset anticipated opposition of organized medicine. In the past similar bills have died because there were few recognized doctors to support them against the testimony of witnesses from the American Medical Association, U. S. Public Health Service, the District of Columbia Medical Society and the District health department. The bill is before the judiciary subcommittee of the House District Committee, and chairman Representative McGehee, Democrat of Mississippi, has promised to set an early date for hearings.

Congresswomen Favor Maternity Care for Wacs

Congresswomen have commented indignantly on the revelation by General Omar Bradley that married women veterans can't have their babies in Veterans Administration hospitals. They were largely in favor of having the regulations changed. General Bradley unearthed a ruling which barred former Wacs, Waves, Spars and women Marines from receiving maternity services in veterans' hospitals at government expense. One official explained that "one must have had some sort of an accident to get government care, and childbirth is not an accident." Representative Helen Gahagan Douglas, Democrat of California, called the ruling unfair, while Representative Francis Bolton, Republican of Ohio, believed that veterans' hospitals should provide obstetric service for women veterans but not antepartum or postpartum care.

Hospital Corps Veterans Organize to Find Jobs

A new veterans' organization, the National Association of Veterans of the Hospital Corps, has been organized to obtain jobs for members in hospitals, laboratories, drug companies and other medical activities. The president is Buford E. Kirwan, retired naval lieutenant and a veteran of both wars. Raymond Watson, the organizer, explains its objectives: "Hospitals, drug companies, laboratories, dentists and industry in general are looking for Hospital Corps veterans to fill positions in their organizations. Supplementing the services of an overworked and insufficient medical doctor population, these men and women of the military hospital corps can contribute much to the nation's health." The headquarters are at 1705 M Street N.W.

Four Drug Firms Receive Highest Corporation Federal Tax Refunds

Four drug firms received the largest federal tax refunds for the fiscal year 1945, according to the treasury list submitted to the House Committee on Executive Expenditures. The refunds were for overpayments by individuals, corporations and estates. Only seven taxpayers received more than $1,000,000 in refunds. Leading this group was the drug firm of Eli Lilly & Co., Indianapolis, with $2,239,065. The other three drug firms were Sharp & Dohme, Inc., Philadelphia, $1,856,744; Parke, Davis & Co., Detroit, $1,610,613, and the Upjohn Company, Kalamazoo, Mich., $1,146,074. The largest refund to an individual was $1,375,000 to Henry F. du Pont of Winterthur, Del.

Health Dangers Cited in Wheat-Saving Order

President Truman's order to conserve wheat for shipment to war devastated countries by providing dark bread for Americans was criticized by a Department of Agriculture official as being dangerous for thousands of persons who cannot eat roughage. It is claimed that provision will be required for people who must have white bread. Under the President's voluntary plan, 80 per cent flour extraction is to be made from wheat kernels, whereas 70 per cent has been normal for white bread. It is claimed that in 1917, when a similar bread campaign was tried in Europe, "11 million persons were casualties of intestinal upsets," and special certificates for white bread had to be issued.

U. S. P. H. S. Launches Research on Cause of Colds

Dr. R. E. Dyer, director of the U. S. Public Health Service National Institute of Health, who will supervise a prolonged research program to find the cause of the common cold, says that his investigators will keep at it until they have the answer. An initial expenditure of $50,000 is planned and it is proposed to find, in addition to the cause of colds, what will prevent and cure them. Dr. Dyer says this is the first "whole hearted attack on the cold problem. Colds cause more disability than any other single disease. We estimate that each day in this country an average of 250,000 persons are out of work because of colds."

Dangers of Farm Well Water Highlighted

Disease dangers in farm water wells which may be prevalent throughout the country are highlighted by the report of Dr. Nelson Podolnick, health officer of Fairfax County, Va., that the overflow from septic tanks has contaminated many wells supplying drinking water for Vienna, Va., and constitutes a grave health menace. His department has tested wells at the owner's request and found them unfit for human use. A complete house to house survey has never been made. One case of typhoid reported in Vienna last year was traced directly to a contaminated well.

Congressional Approval Expected of Federal Employee Health Bill

Favorable congressional action is expected soon on the federal employee health bill, which passed the House several months ago. Senator Sheridan F. Downey, Democrat of California, chairman of the Senate Civil Service Committee, thinks that a quick approval will be forthcoming in the Senate. The bill would allow federal agencies to set up small medical units to safeguard the health of employees.

Hearings Resume of Washington Hospital Center

The House District Committee will resume hearings Wednesday on the bill to erect a $20,000,000 hospital center in the nation's capital. The District of Columbia has opposed being obliged to contribute funds. It is hoped that the hearing will decide whether one third of the costs of site and construction should be repaid by contributing nonprofit private hospitals, by the District government, or whether the whole cost should be carried by the federal government.

Army Aerial Search and Rescue Program in Maryland

The Army's aerial search and rescue program will have its headquarters at Andrews Field Army Air Base in Maryland, adjacent to the national capital. The 62d AAF Base Unit will administer and coordinate the activities of nineteen rescue units throughout the United States. The program consolidates the elaborate search and rescue systems established at the outset of the war by each of the four continental air forces.

Veterans Administration to Hire 500 Hospital Clerks

The Veterans Administration plans to relieve its doctors of heavy "paper work" so that they can devote more time to patients. The agency has authorized its hospitals to hire 500 clerk-typists for work in hospital wards. The clerk-typists will answer telephones, direct patients to clinics, take dictation from physicians and nurses, type hospital records and handle other clerical duties. They will be hired in the district adjacent to the hospital served.

"Fugitive" Narcotics Recovered from Soldiers

Elmer L. Irey, chief coordinator of treasury law enforcement agencies, in his report to Treasury Secretary Vinson, reports that a considerable quantity of what is known as "dope fugitive" is being recovered from returning soldiers. As in the first world war, Allied officials are trying to corral all surplus narcotic supplies in wartorn areas, but quantities of such drugs are finding their way into the illicit United States and world trade.

Dr. J. Wayne McFarland Appointed Magazine Editor

Dr. J. Wayne McFarland has been appointed editor of *Life and Health*, a Seventh Day Adventist publication. He will serve as assistant secretary for health education of the medical department of the denomination and as a consulting physician in physical medicine at the Washington Sanitarium and Hospital.

Uncertain Future of Hospital Center Legislation

The future of the bill to create a $20,000,000 hospital center in Washington is uncertain, since the subcommittee yielded to District of Columbia demands that the District be exempted from sharing in the cost. The bill went to the full House District Committee "without recommendation."

Council on Medical Service and Public Relations

PREPAID MEDICAL CARE NEWS

Kansas Physicians' Service

After three years' study of various prepaid medical plans in operation in the United States and after enabling legislation had been passed by the 1945 Kansas legislature, all forms have been approved by the commissioner of insurance for the state of Kansas, from whom the certificate of authority was issued on December 11. This certificate, therefore, places Kansas Physicians' Service into operation.

Kansas Physicians' Service is a nonprofit corporation organized by the Kansas Medical Society. It exists for the purpose of enabling the people of Kansas to purchase subscription agreements entitling them to prepaid surgical and medical care. The details of the plan are as follows: Benefits to be included are surgical, in which all types of surgery may be covered immediately except that an eight months waiting period is required for tonsillectomies and adenoidectomies and for preexisting conditions. The second benefit is for obstetrics, which is available to all subscribers holding family benefits after eight consecutive months' membership. All accident cases involving fractures and dislocations are covered immediately and a maximum of $15 per year is allowable for diagnostic x-rays in accident cases only. The fourth benefit is for nonsurgical illness. Here, benefits begin on the fourth day of hospitalization and continue for thirty days thereafter.

The Kansas program is a combination of a service and indemnity plan whereby families with a yearly income of less than $2,400 will be given a service benefit and those making over that amount of money will receive an indemnity type of benefit. The decision as to which is to be applied rests with the doctor and the patient involved.

Free choice of physicians is assured, and participation in the plan is of course strictly voluntary.

The officers of the corporation are Dr. Barrett A. Nelson, Manhattan, president; Dr. John L. Lattimore, Topeka, vice president; Dr. W. M. Mills, Topeka, secretary-treasurer.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

District Meeting.—The Fifth Councilor District Medical Society was addressed in El Dorado, January 8, by Drs. Alton Ochsner, New Orleans, on "Carcinoma of the Lung: Early Diagnosis and Possibilities of Treatment," and William W. Scott, Chicago, on "The Urinary 17-Ketosteroids: The Rise of Our Knowledge of Their Origin and Excretion and Their Clinical Significance."

CONNECTICUT

Personal.—Dr. James C. Fox Jr., formerly clinical professor of neurology at Yale University School of Medicine, New Haven, has been appointed assistant medical director of the Hartford Hospital.——Dr. Albert W. Snoke, Rochester, N. Y., assistant director of Strong Memorial Hospital, has been named director of the New Haven Hospital.

Physician Honored.—Dr. D. C. Y. Moore, Manchester, was guest of honor at a dinner recently given by the Manchester Medical Association in recognition of his completion of fifty years in the practice of medicine. Dr. George A. F. Lundberg, Manchester, was toastmaster and, on behalf of the association, presented Dr. Moore with a gold chain and charm on which was inscribed "Fifty Years of Service as a Physician."

MASSACHUSETTS

Manfred Bowditch Goes to Saranac.—Mr. Manfred Bowditch, director, division of occupational hygiene, Massachusetts State Department of Labor since the establishment of the division, has joined the staff of the Saranac Laboratory at Saranac Lake, N. Y., as field director.

Francis Denny Retires.—Dr. Francis P. Denny retired recently as health officer of Brookline after many years of service to the community. Dr. Denny graduated at Harvard Medical School, Boston, in 1895 and started to practice in Brookline in 1897. According to the *New England Journal of Medicine* he established a bacteriologic laboratory in the city in 1899, the first in Massachusetts outside Boston, a tuberculosis pavilion as part of the Brookline contagious disease hospital in 1914 and a dental dispensary in 1915. He inaugurated immunization against diphtheria in 1923. For twenty-six years Dr. Denny was responsible for the quarterly publication of the *Brookline Health Bulletin*, a sheet that is delivered to every household in the town, printing regularly the results of milk examinations, the rating of restaurants and much other timely health advice. During his term of office Brookline was three times the winner of the health conservation contest sponsored by the United States Chamber of Commerce. Dr. Denny has been president of the Massachusetts Public Health Association, the Norfolk District Medical Society and the Brookline Anti-Tuberculosis Society and a member of the executive committee of the Massachusetts Tuberculosis League, now being its honorary vice president. The new health officer is Dr. Alfred L. Frechette, formerly state health officer of New Hampshire.

State Plan Provides for Segregation of Mentally Ill Children.—The Massachusetts Department of Mental Health has announced that the entire state, excepting Boston, has been established as a state hospital district for children 15 years of age or younger. Effective January 1, no children under 15 years of age are to be admitted to the following state hospitals: Boston, Danvers, Foxborough, Gardner, Grafton, Medfield, Northampton, Taunton, Westborough and Worcester. For the entire state children in this age group are to be admitted to the Metropolitan State Hospital, Waltham, with the exception that in the city of Boston children within this age group may be admitted to the Boston Psychopathic Hospital for a period of study only. Any case from Boston requiring continued care should be sent directly to the Metropolitan State Hospital. This new plan has been arranged in order that children may be properly segregated from mentally ill adults and, at the same time, receive adequate educational and recreational facilities. At the Metropolitan State Hospital a 100 bed unit has been set up to be used only for children. At present this will be used for psychotic children only, but it is planned that as soon as practical this unit will also be used for the purpose of studying and treating behavior problems in children. The unit has been arranged so that the psychotic children will be separated from the nonpsychotic study cases. The department has requested approval for the appointment of personnel for this unit consisting of a clinical director, psychiatric social worker, psychologist, junior clerk and stenographer, dietitian, two head nurses and an institutional school teacher.

MINNESOTA

Special Lectures.—The annual George Chase Christian Lecture in the field of cancer research or treatment was delivered at the University of Minnesota Medical School, Minneapolis, February 7 by Leonell C. Strong, Ph.D., associate professor of anatomy, Yale University School of Medicine, New Haven. His subject was "Mice, Men and Malignancy." Dr. Strong also gave a lecture February 6 on "Experimental Gastric Carcinoma in Mice."——Dr. T. Duckett Jones, associate professor of medicine, Harvard Medical School, Boston, gave the annual Clarence Martin Jackson Lecture at the University of Minnesota Medical School, Minneapolis, on rheumatic fever. The lecture is sponsored by the Phi Beta Pi medical fraternity.

Chiropractor Receives Suspended Sentence.—On November 26 Alfred Peterson, Duluth, chiropractor, received a suspended sentence of one year in the Minnesota Workhouse on condition that he surrender his medicines to be destroyed by the state and that he refrain from practicing healing in any manner anywhere in the state of Minnesota. Peterson agreed. He was arrested in Minnesota November 20 following an investigation by the Minnesota State Board of Medical Examiners and the Minneapolis police department, which disclosed that he claimed to have studied but held no license to practice any form of healing in the state. He was making regular trips to interview patients at hotels in Virginia, Hibbing, Grand Rapids, Brainerd, St. Cloud, Mora, Cambridge and Minneapolis and stated "I will give $1,000 to any medical association, any cancer research institution, or any one if they can prove that these testimonials are not true." In his literature Peterson claimed to have "discovered a cure for heart *trouble, gallstones, ulcers, eczema, rheumatism, sinus, and that* dreaded disease cancer." On one of his trips to Mora, Peterson made the mistake of furnishing the same medication to 7 patients with seven different ailments.

NEW YORK

Supreme Court Upholds Regulation of Board of Health.—In a decision announced recently, Justice Swezey of the New York Supreme Court denied the request of a joint committee of teachers' organizations in New York City for an injunction to restrain the New York City Board of Education and the New York City Department of Health from enforcing a regulation to require teachers to have a chest x-ray every two years. A regulation of the sanitary code, adopted by the city board of health, requires teachers and other employees who work in the schools and come in contact with the children to procure biennially a certificate from a physician or from the board of health based on a chest x-ray examination and certifying that such employee is free from active tuberculosis. The teachers contended that "the board of health was not empowered to enact such a regulation, that the regulation in addition to being beyond the scope of the board's powers was arbitrary, capricious and unreasonable and was contrary to the constitution and laws of the United States and the constitution and laws of the state of New York." It was contended further that "this regulation denied equal protection of the law to the persons directed to submit to such examination and was discriminatory in that it was applicable to no other person or group of persons who come in contact with children or whose work placed them in frequent contact with persons who might be infected with the disease." The board of health and board of education held that the regulation was a valid and reasonable exercise of the powers vested by law in the board of health to promulgate regulations for the security of life and health in the city and that it was not "arbitrary, capricious or discriminatory" (THE JOURNAL, June 2, 1945, p. 378).

New York City

The Harvey Lecture.—Dr. Stafford L. Warren, professor of radiology, University of Rochester School of Medicine and Dentistry, will deliver the fifth Harvey Society Lecture of the current series at the New York Academy of Medicine, February 21. Dr. Warren will speak on "The Story of Nagasaki."

NORTH CAROLINA

Bowman Gray Activities.—Bowman Gray School of Medicine at Wake Forest College, Winston-Salem, announces that Dr. Robert B. Lawson, assistant professor of pediatrics, returned from a year's leave of absence spent in virology at the George Williams Hooper Foundation, University of California. Dr. Lawson will resume his regular duties in the department of pediatrics, and Dr. C. Hampton Mauzy, recently discharged from the army, has resumed his position on the faculty as assistant professor of obstetrics and gynecology. His status has been changed from part time to whole time. Dr. John R. Williams Jr. has resigned as assistant professor of medicine to become associated with his father, Dr. John R. Williams Sr., in the practice of medicine in Rochester, N. Y. New appointments include Dr. Weston M. Kelsey, Westport, Conn., instructor in pediatrics. He has recently been discharged from the army, in which he obtained the commission of captain. William E. Cornatzer, Ph.D., assumed the position of assistant professor of biochemistry. Dr. Joseph T. Phillips Jr., Washington, is the new instructor in biochemistry.

OHIO

Health Museum Buys New Home. — The Cleveland Health Museum plans to hold a formal opening of its new home the last week in April. The building, formerly known as Garfield House and occupied by the Cleveland Speech and Hearing Center, will be used primarily to accommodate the Dickinson collection of sculptural models of human reproduction (The Journal, July 21, 1945, p. 893). In addition it will augment space for other existing exhibits and new exhibits planned to cover mental hygiene, industrial health and a new series pointing the way to healthier and happier old age, furnish additional space for the health education laboratories, particularly the new plastics department, and provide increased facilities for teaching in the postgraduate field of health education. The newly acquired property consists of 2⅝ acres. The principal building is a terra cotta, stone and brick structure of thirty-nine rooms on four floors, including the basement. The Cleveland Speech and Hearing Center, which formerly occupied the building, has established new quarters at 11206 Euclid Avenue on the campus of Western Reserve University (The Journal, June 9, 1945, p. 453). The Cleveland Health Museum was incorporated in 1936 by a group of physicians, dentists, members of the Cleveland Health Council and lay persons to find and utilize popular methods of teaching the public basic facts about the human body and its care (The Journal, Dec. 7, 1940, p. 2012). Dr. Bruno Gebhard has been the director of the museum since it officially opened.

New home of the Cleveland Health Museum.

PENNSYLVANIA

The State's School Health Program.—The school health act recently enacted by the general assembly in Pennsylvania provides for a complete medical and dental examination of all children of school age and teachers and other school employees in the public and private elementary and secondary schools. An appropriation of $4,000,000 is provided to cover the cost of the program in the commonwealth for the next biennium. The examination of school children must be held every two years while they are members of the first, third, fifth, seventh and ninth grades. All school employees must have complete medical and dental examinations every two years. Not more than four medical and eight dental examinations per hour may be made by each examiner. The act shall not apply in cases of religious objection unless exemption would menace the health of other persons. The school child or employee may have the health or dental examination made by his private physician or dentist at his own expense on forms prescribed by the state, submitting the record of examinations to the local school health authorities. The local school district will receive from the state $1.50 for each medical examination and 75 cents for each dental examination.

Philadelphia

Plastic and Reconstructive Surgery Meeting.—The American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, Inc., will be addressed at the Philadelphia County Medical Society February 28 by Drs. Chevalier L. Jackson on "Plastic Surgery of the Larynx and Cervical Esophagus," David Myers on "Missile Injuries of the Mastoids, Sinuses and Maxillofacial Structures" and John V. Blady on "Maxillofacial Surgery in Cancer."

TEXAS

Fund for Needy Students.—The Medical Dames of the University of Texas Medical Branch, Galveston, has established a fund for the annual award of an appropriate prize to the most scholarly and needy first year student. The Medical Dames, which was organized by the wives of the medical students in the fall of 1944, plans to maintain an active program for the promotion of the welfare of the medical branch.

Research Council Created.—Dr. Robert M. Moore, professor of Surgery, University of Texas Medical Branch, Galveston, has been named chairman of a research council recently created at the school. The council was selected by the faculty to afford guidance and advice for staff members engaged in research. The program will assure coordination and uniformity of standards of research efforts. Dr. Moore developed the laboratory of experimental surgery at the school prior to entering the U. S. Army, where he was commanding officer of the 127th General Hospital.

Baylor Hospital Staff Reorganized.—The medical staff at Baylor University Hospital, Dallas, has been reorganized and a medical board created to supervise the teaching program at the hospital. The new board is composed of thirteen Dallas physicians appointed by the trustees as chiefs of various medical and surgical services. Its purpose will be to raise hospital standards, furthering medical instruction and medical research, direct the staff and organization and supervise the teaching program for residents and interns. It will also cooperate in the teaching of medical students at Southwestern Medical College, Dallas, and assist in dissemination of medical information to the public. Membership of the new board includes:

Dr. Earl F. Weir, Council Bluffs, Iowa, anesthesiology.
Dr. Henry M. Winans, Dallas, internal medicine.
Dr. Albert P. D'Errico, Dallas, neurologic surgery.
Dr. William K. Strother Jr., Dallas, obstetrics and gynecology.
Dr. Lester H. Quinn, Dallas, ophthalmology.
Dr. Felix L. Butte, Dallas, orthopedic surgery.
Dr. Lyle M. Sellers, Dallas, otolaryngology.
Dr. Joseph M. Hill, Dallas, pathology.
Dr. Robert L. Moore, Dallas, pediatrics.
Dr. Guy F. Witt, Dallas, psychiatry and neurology.
Dr. Frank M. Windrow, Ann Arbor, Mich., radiology.
Dr. Harry Cochran, Dallas, surgery.
Dr. Alfred I. Folsom, Dallas, urology.

Officers of the new board are Dr. Winans, chairman, Dr. Folsom, vice chairman, and Dr. Hill, secretary-treasurer. The board has selected the staff which will carry on the active teaching program. All other members of the Dallas County Medical Society will be included on the courtesy list. These staff appointments, presented on unanimous recommendation of the medical board, have been approved by the trustees for the year ending December 31. The staff will be composed of four classifications, as follows:

Consultants: Men who will not take an active part in direction of the program but who, because of their outstanding qualifications and experience, will be looked to for advice and counseling.

Attending Physicians: Men who have limited their work to one of the certified specialties and who have contributed much effort and interest to Baylor's teaching program in the past. From this group will be drawn most of the teachers and clinicians for the teaching program.

Associate Attending Physicians: Those who are qualified as specialists by their certifying boards or who have equivalent qualifications and who have shown much interest in the teaching program but who are less experienced professionally or in the community.

Junior Attending Physicians: Those just out of residency or internship, now working toward certification by their specialty boards, who wish to devote time toward assisting in the teaching program. As they gain experience these men, like the associate attending physicians, will be advanced to the higher classifications, thus building a reservoir of medical teaching talent for future development of the program.

VERMONT

Personal.—Dr. Paul K. French, Burlington, who recently retired from the Army Medical Corps with the rank of lieutenant colonel, has been promoted from associate professor to professor of clinical medicine at the University of Vermont College of Medicine, Burlington.——Dr. Stewart Ross, Rutland, has been elected a trustee of Middlebury College for a period of five years starting July 1.

Society News.—On January 15 Dr. William E. Brown, dean, University of Vermont College of Medicine, Burlington, addressed the Windsor County Medical Society at the Woodstock Inn, Woodstock, on the establishment of a state medical center at Burlington, built around the University of Vermont Medical School, by which it is hoped to provide specialized and clinical work for the benefit of Vermont residents and doctors. He discussed the same project before the Rutland County Medical Society and the Rutland Hospital staff at the Hotel Berwick, January 17.

Activities of State Medical Society.—During the past year the Vermont State Medical Society created the position of executive secretary and named Mr. John W. Brownlee as the first incumbent. Offices of the society have been set up at 128 Merchants Row, Rutland. The society also started the publication of a monthly *News Letter,* which carries discussions of national and local interest. The publication of a state medical journal is now under consideration. Officers of the state medical society chosen at a recent meeting of the house of delegates of the society include Drs. Frank C. Angell, Randolph, president-elect; Leon E. Sample, St. Albans, president; Ellsworth L. Amidon, Burlington, vice president; Benjamin F. Cook, Rutland, secretary, and David Martin, Essex Junction, treasurer. The next annual session will be held in October, the exact dates to be determined later.

VIRGINIA

Changes in Health Personnel.—Dr. William Grossman, Richmond, director of the bureau of communicable disease control, returned to the Virginia State Department of Health from the military service as of January 1. Dr. Donald K. Freedman, Washington, Surgeon (R), U. S. Public Health Service, who was on loan to the Virginia State Department of health and who has been acting as health officer of the Peninsula Health District, was withdrawn by the public health service effective Dec. 8, 1945.

Spring Graduate Course.—The Gill Memorial Eye, Ear and Throat Hospital announces its spring graduate course in Roanoke April 1-6. The course will cover ophthalmology, otology, rhinology, laryngology, faciomaxillary surgery, bronchoscopy and esophagoscopy. Among the participants in the course will be:

Dr. Louis H. Clerf, Philadelphia.
Dr. William R. Graham, Richmond.
Dr. George P. Guibor, Chicago.
Dr. William F. Hughes Jr., Baltimore.
Dr. James R. Jaeger, Philadelphia.
Dr. Merrill J. King, Boston.
Dr. Ferdinand L. P. Koch, New York.
Dr. Perrin H. Long, Baltimore.
Dr. James H. Maxwell, Ann Arbor, Mich.
Vice Admiral Ross T. McIntire, Washington.
Dr. Paul M. Moore Jr., Cleveland.
Dr. Werner Mueller, Boston.
Dr. Frank Payne, New York.
Dr. Charles A. Perera, New York.
Dr. Emund B. Spaeth, Philadelphia.
Dr. Isaac S. Tassman, Philadelphia.
Selman A. Waksman, Ph.D., New Brunswick, N. J.

WEST VIRGINIA

Personal.—At a meeting of the Public Health Council of West Virginia in Charleston, January 7, Dr. Walter E. Vest, Huntington, was reelected president for a fifth consecutive two year term; he has been a member of the council since 1933 and has served as its president since 1937.——Dr. Frederick C. Kluth, Charleston, U. S. Public Health Service, who has served as venereal disease control officer for Charleston and Kanawha County for the past three years, has been transferred to Columbus, Ohio, where he is in charge of a rapid treatment center similar to the Kanawha Medical Center, South Charleston.

Confidential Report Form for Tuberculosis.—A new confidential report form to be used for reporting tuberculosis has been adopted by the state health department and distributed to all local health departments. The new form replaces the old form, CD-8, which has been in use for several months. Local health departments are requested to report all new cases of tuberculosis on the new form and submit them weekly to the Collaborating Epidemiologist, State Health Department. The reports are to be treated as confidential and mailed under cover. While the card is at present used *only* by local public health departments, it is probable that the state health department will ask that the form be approved by the West Virginia State Medical Association so that it can be used by doctors over the state. The new form has already been approved by the Public Health Council.

Payment of Doctors' Bills.—A change in the regulations concerning the submission by doctors of bills for services rendered has been announced by Mr. E. B. Pennybacker, state compensation commissioner, effective immediately. All bills *must now be submitted in duplicate,* and medical reports must be filed before or at the same time bills are rendered. This change in procedure will protect the doctor who submits his bills within the prescribed ninety day limit, notwithstanding any delay in having the bill approved within that time by the subscriber or employer. The workmen's compensation act was amended at the 1943 session of the legislature so as to require the submission of bills within ninety days after services are rendered. Frequently the bills, which have to be approved by the employer, have not been returned to the compensation commissioner before the expiration of the time limit, which has resulted in a great deal of confusion, and delay in the payment of such bills. In the future, if no objection to the payment of the bill is received by the commissioner from the employer within fifteen days after it is submitted by the doctor, payment will be authorized to the same extent as if the bill had been regularly approved.

WISCONSIN

Physicians Honored.—Dr. George E. MacKinnon, who has practiced in Prentice and the surrounding area for thirty years, was honored when Price County set aside November 15 as "Dr. MacKinnon Day." The celebration included a parade, a banquet, a musical program and a community dance. Dr. MacKinnon graduated at Queen's University Faculty of Medicine, Kingston, Ont., in 1914. He started in practice in Tripoli in 1915, going to Prentice the following year.——Dr. Mina B. Glasier, Bloomington, enjoyed a community three day celebration of her eighty-sixth birthday, which was November 5. Dr. Glasier, an honorary member of the state medical society, was secretary of the Grant County Medical Society for thirty-five years, its president for one year, a member of the state board of health for fourteen years and recipient of the council award of the state medical society in 1932, according to the state medical journal. She has practiced in Bloomington for sixty-one years.

ALASKA

Personal.—Dr. David M. Cowgill has been appointed district health officer with the Alaska Territorial Department of Health, with offices in Anchorage. He was formerly health officer in Amarillo, Texas.

GENERAL

Campaign Against Noise.—The National Noise Abatement Council, in announcing its 1946 program, urges reestablishment of noise control on the agenda of all city planning commissions. The council will present noise abatement achievement awards to five cities in the United States which show the most conclusive evidence of noteworthy accomplishments of the elimination of needless street noise and in the reduction of noise in industry, in the office and in the home.

Meeting of Pediatric Board.—At the annual meeting of the American Board of Pediatrics in Atlantic City, Dec. 6, 1945, Drs. C. Anderson Aldrich, Rochester, Minn., was elected president, Donovan J. McCune, New York, vice president, and Lee F. Hill, 3309 Forest Avenue, Des Moines, Iowa, secretary-treasurer. On and after May 1, the application fee for the American Board of Pediatrics will be $100. The next written examination of the board will be held locally under a monitor, March 22. Oral examinations will be held in Cleveland April 27-28 and, if sufficient applications are received to warrant this examination, in San Francisco July 1-5.

Student Loan Fund for Work in Gynecology.—The woman's auxiliary of the Southern Medical Association at its recent annual meeting in Cincinnati voted to use its Jane Todd Crawford Memorial Fund as a student loan fund to help medical students or physicians from the South desiring to do postgraduate work in gynecology. The recipients are to be recommended by the dean of the medical school where they are in attendance or by the local medical society of which they are members. Approval was to be submitted by a committee of three elected by the executive board of the Woman's Auxiliary of the Southern Medical Association. The fund honors the first woman to submit to an ovarian operation, which was performed by Dr. Ephraim McDowell. Jane Todd Crawford is also honored annually with a special day named for her.

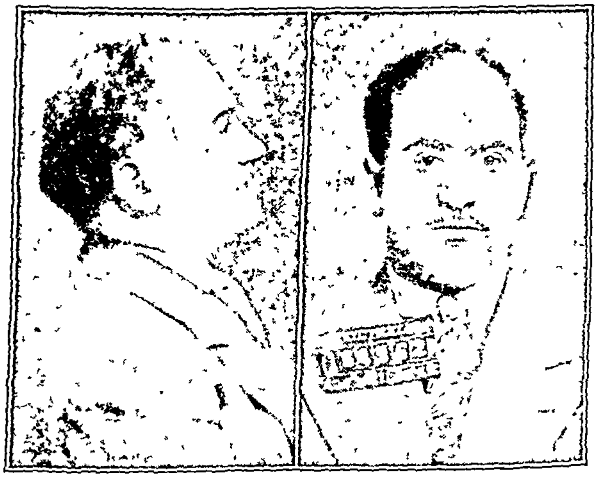
New Publications.—The Washington Institute of Medicine announces the publication of the *Quarterly Review of Pediatrics,* beginning with the February issue. Dr. Irving J. Wolman, Children's Hospital, Philadelphia, 1740 Bainbridge Street, Philadelphia 46, is the editor in chief. In addition, sixteen members comprise the editorial board. The institute also announces that it will bring out in March a *Quarterly Review of Urology.* Dr. Hugh J. Jewett, Baltimore, is the editor in chief. The object of this quarterly is to present a panoramic picture of the current world progress in urology through the publishing of abstracts and the indexing, as far as possible, of everything that has appeared in the world medical literature pertaining to urology. Henry J. Klaunberg, Ph.D., is president of the Washington Institute of Medicine, 1720 M Street N.W., Washington 6.

Record Set for Hospital Births.—Ninety-one out of one hundred of the babies born under the emergency maternity and infant care program in 1944 were born in hospitals as compared with seventy-six out of one hundred for all infants in that year, according to the Children's Bureau, U. S. Department of Labor, January 27. In ten states the record was even more remarkable, with less than 2 per cent of the births under the government program being home deliveries. Even in states where the percentage of home deliveries of such births was highest, it was far below the percentage for all infants. In Mississippi, for instance, of all births only 3 out of 10 took place in hospitals, whereas 7 out of 10 servicemen's babies cared for under the program were hospital born. It is estimated that almost $40,000,000 from federal funds has been paid to hospitals from state agencies.

Robert Goodhart Named Director of the Vitamin Institute.—Dr. Robert S. Goodhart, Forest Hills, N. Y., since March 1943 chief of the industrial feeding program division, War Food Administration, U. S. Department of Agriculture, has been named scientific director for the Institute for Vitamin Research, Inc. Dr. Goodhart recently returned from Japan, where he studied nutritional problems of the Japanese people. He expects to complete this project by March 1, when he will assume his new duties. The Institute for Vitamin Research was formed at a meeting at the Waldorf Astoria, New York, Jan. 29, 1945 (The Journal, Feb. 17, 1945, p. 414). It maintains headquarters in the office of its secretary, Henry K. Urion, of O'Connor and Farber, its attorneys, 120 Broadway. Its purposes are to maintain continuing research on "problems in nutrition, particularly as they relate to vitamins, to the end that the health and welfare of mankind may be improved through better nutrition." The institute proposes to make grants to individuals and institutions for research and to provide scholarships and fellowships. The institute also will study and adopt "proper standards for the manufacture and sale of vitamin products." Dr. Goodhart graduated at New York University College of Medicine-Bellevue Hospital Medical College in 1934.

Artificial Limb Program for Soviet Union.—The American Society for Russian Relief, Inc., has launched a million dollar program to obtain needed material for the rehabilitation of amputation cases in the Soviet Union. The program includes the attempt to equip a network of hospitals specializing in the care of amputees in the Soviet Union and a central factory with regional workshops in various Soviet Republics to manufacture artificial limbs. Everything will be supplied, from thousand dollar turret lathes and disk grinders to laundry equipment, surgical instruments and even doctors' and nurses' uniforms. Plans call for a central hospital in Moscow to be supplied with 2,000 beds, laundry equipment to handle 23,500 pounds of wash a day and all necessary medical equipment, including a complete chemical research laboratory. Attached to this hospital will be an artificial limb factory to be equipped with American machines and basic raw materials for the manufacture of limbs, including pressed felt, vulcanized fiber sheets, finishing lacquers, glues and copper nails. Along with basic machinery such as drill presses, duplicating lathes, welding machines, riveting machines, electric drills and sewing machines, the agency also is shipping hand tools, such as files, hammers, hack saws, nails and industrial electric vacuum cleaners for factory and hospital use. The project also includes equipping of regional hospitals in the various Soviet Republics with their own artificial limb work shops. After the initial operation at the central hospital and manufacture of the desired limb at the factory, the patient will be sent to the regional hospital nearest his home. Here he will convalesce and the final fitting of the limb will be made. An announcement stated that a number of amputation cases in the Soviet Union is so great that it has not yet been totaled and that civilians, including children, are still being maimed by exploding mines so cunningly buried that they cannot always be detected. The American Society for Russian Relief, formerly Russian War Relief, Inc., has its headquarters at 5 Cedar Street, New York 5.

Fugitive Physician Sought on Abortion Charge.—Dr. Louis G. Small, who on April 1, 1942 was arrested on the charge of abortion, is being sought by the District Attorney's Office of the County of New York. Small was indicted for and convicted of nine separate felonies of abortion and a general conspiracy to maintain a public nuisance, to wit, an abortion mill. After his conviction he was admitted to $12,000 bail pending appeal, but when the judgment of conviction was affirmed he forfeited his bail and took refuge in the state of Georgia. According to the District Attorney's Office, Small sought to defeat extradition proceedings by having himself arrested by a local sheriff on the charge of practicing medicine without a license in Georgia. The District Attorney's Office of the County of New York succeeded in establishing the right to his custody, but the physician defeated extradition by "escaping" on March 12, 1944 from the custody of the local sheriff charged with the duty of detaining him. The District Attorney's Office is of the opinion that while it has no record of Small's present whereabouts he is practicing medicine or operating an abortion mill somewhere within the United States. Small is said to travel usually with his wife, Florence Essl Small, who is described as being about 5 feet 7 inches in height and weighing 120 pounds. She is said to have blue eyes, blond hair with fair complexion and usually acts as a model and commercial artist. Small's conviction in New York for operating an abortion mill with two other physicians was reported in The Journal May 15, 1943 and his arrest in Georgia Dec. 4, 1943. On March 15, 1944 the Maryland State Board of Medical Examiners revoked a license obtained by him in December 1942. Small was born in Russia April 17, 1902. He obtained his premedical education at New York University and graduated at the University of Arkansas School of Medicine, Little Rock, in 1927.



Louis G Small, aged 43, height 5 feet 4 inches, weight 150 pounds, brown eyes, black hair, dark complexion, small black mustache.

Government Services

Hospital Leased to State of Georgia

The Surplus Property Administration has authorized the Federal Works Agency to negotiate a lease for five years with the state of Georgia for the Battey General Hospital at Rome, Ga. The lease will carry an option to purchase later. The hospital installation, recently declared surplus by the War Department, consists of approximately 160 acres of government owned land improved with fully equipped hospital buildings and various facilities necessary for the operation of the hospital. The state of Georgia declared that it had urgent need for increased hospital facilities for a tuberculosis sanatorium. It declared that its present state tuberculosis sanatorium will be converted into a mental institution or a female prison, both of which are urgently needed by the state. The Federal Works Agency has been authorized to issue immediately a temporary occupancy permit. Following a ten day notice of availability to all government agencies, and in the absence of an acceptable proposal from a holder of a higher priority or a proposal from any state or local government having a priority equal to that of the state of Georgia, the Federal Works Agency will negotiate the terms of the proposed lease.

Deaths

Alpheus Felch Jennings ⊕ Detroit; Harvard Medical School, Boston, 1910; born in Detroit June 22, 1884; assistant professor of clinical medicine at the Wayne University College of Medicine; extramural lecturer in postgraduate medicine at the University of Michigan; specialist certified by the American Board of Internal Medicine; member of the American Clinical and Climatological Association; fellow of the American College of Physicians; recently finished a term as chairman of the board of trustees of the Wayne County Medical Society; medical officer at Selfridge Field during World War I and, after serving as assistant chief of medical service at Camp Custer, ordered overseas, where he served with Evacuation Hospital number 21 in France; served with various units and discharged in May 1919 with the rank of major; consultant in medicine at the U. S. Marine Hospital; president of the board of trustees and chief of staff of the Charles Godwin Jennings Hospital, where he died November 16, aged 61, of carcinoma of the bladder and bilateral hydronephrosis.

Walter Scott Franklin ⊕ Santa Barbara, Calif.; Cooper Medical College, San Francisco, 1898; clinical professor of ophthalmology emeritus at the University of California Medical School in San Francisco, where he was on the staffs of the University of California Hospital and the Shriners' Hospital for Crippled Children; specialist certified by the American Board of Ophthalmology; member of the Western Ophthalmological Society and the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; on the staffs of the Santa Barbara General Hospital, St. Francis Hospital and the Santa Barbara Cottage Hospital, where he died January 2, aged 67, of uremia due to hypertension.

Oliver V. Schuman ⊕ Columbia City, Ind.; Chicago Medical College, 1889; honorary member of the Indiana State Medical Association; formerly county and city health officer; served on the advisory board during the construction of the Indiana State Sanatorium at Rockville, where he served as a member and president of the board; for many years vice president of the Farmers Loan and Trust Company; helped to organize the woolen mills in Columbia City, serving on the board of directors from the beginning of the mill until his death; died October 23, aged 81, of coronary occlusion and diabetes mellitus.

Frederick Jennings Smith, Kankakee, Ill.; Miami Medical College, Cincinnati, 1905; member of the American Medical Association, Kansas Medical Society and the American Psychiatric Association; served during World War I; at one time medical inspector of the city schools in San Diego and on the staffs of the U. S. veterans hospitals in North Little Rock, Ark., and Palo Alto, Calif.; formerly assistant physician in neuropsychiatry at the Watertown State Hospital in East Moline; on the staff of the Kankakee State Hospital; died October 4, aged 65, of heart disease.

Laura Elizabeth McClure ⊕ Lansdowne, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1928; clinical associate professor of pediatrics at the Woman's Medical College of Pennsylvania; specialist certified by the American Board of Pediatrics, Inc.; member of the American Academy of Pediatrics; medical director of the Babies' Hospital and on the staffs of the Hospital of the Woman's Medical College and St. Christopher's Hospital for Children, all in Philadelphia; died in New Wilmington October 17, aged 41, of carcinoma of the ovary and broad ligament.

Joseph Schapiro ⊕ Union City, N. J.; Columbia University College of Physicians and Surgeons, New York, 1905; member of the American Orthopsychiatric Association; for many years medical director of the Union City public schools; at one time school physician; served overseas during World War I; on the courtesy staff of the Medical Center of Jersey City; on the staff of the North Hudson Hospital, Weehawken; senior clinician of the mental hygiene clinic of the Mount Sinai Hospital in New York; died November 13, aged 65, of coronary thrombosis.

Jacob Thorkelson ⊕ Butte, Mont.; College of Physicians and Surgeons, Baltimore, 1911; member of the American Association of Anatomists, Aero Medical Association and the Association of Military Surgeons of the United States; served as surgeon to the Montana State Hospital at Warmsprings; visiting surgeon to St. Ann's Hospital in Anaconda and St. James Hospital; lieutenant commander, medical corps of the U. S. Naval Reserve, not on active duty; formerly a Republican congressman from Montana; died November 20, aged 69.

Charles Bee Alexander, Alhambra, Calif.; Barnes Medical College, St. Louis, 1907; served in the intelligence service during World War I; on the staffs of the Garfield Hospital, Monterey Park, Los Angeles General Hospital and the Alhambra Hospital, where he died October 21, aged 70, of cerebral hemorrhage and diabetes mellitus.

George Anderson, Alpha, Ohio; College of Physicians and Surgeons, Baltimore, 1891; died October 19, aged 78, of uremia.

John Frederick Bening, Clarinda, Iowa; University of Nebraska College of Medicine, Omaha, 1904; member of the American Medical Association; past president of the Page County Medical Society; on the staff of the Clarinda State Hospital; died October 13, aged 69, of coronary thrombosis.

Charles James Berger, Pottsville, Pa.; Medico-Chirurgical College of Philadelphia, 1903; died September 4, aged 76, of bronchopneumonia and arteriosclerosis.

Chester Abram Brink, Pleasanton, Neb.; College of Physicians and Surgeons of Chicago, 1893; served as a member of the Valley County Board of Health, coroner of Valley County and physician to the Valley County Insanity Board; died October 21, aged 75, of cerebral hemorrhage and senility.

Samuel Slaughter Caruthers, Duck Hill, Miss.; Memphis (Tenn.) Hospital Medical College, 1905; served during the Spanish-American War and World War I; died in Pacific Grove, Calif., November 12, aged 69, of coronary thrombosis.

Lorin Cone Collins ⊕ Chicago; Northwestern University Medical School, Chicago, 1900; major in the medical corps of the U. S. Army during World War I, serving as post surgeon at Chanute Field; formerly on the staffs of the Children's Memorial and Lutheran Memorial hospitals; member of the associate staff of the Grant Hospital, where he died December 25, aged 69, of carcinoma of the prostate.

Thomas James Connolly, Crescent Springs, Ky.; Bennett Medical College, Chicago, 1913; died in St. Elizabeth Hospital, Covington, September 26, aged 71, of Parkinson's syndrome.

Charles Jacob Dietrich ⊕ Reading, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1903; member of the Radiological Society of North America, Inc.; on the staff of St. Joseph's Hospital; died September 10, aged 66, of hypertension and arteriosclerosis.

James Irenaeus Doyle ⊕ Rapid City, S. D.; Loyola University School of Medicine, Chicago, 1924; on the staffs of St. John's, McNamara and Black Hills General hospitals; died October 17, aged 50, of coronary occlusion.

Philip P. Fisher ⊕ Sharon, Pa.; College of Physicians and Surgeons, Baltimore, 1881; died September 22, aged 89, of cardiovascular disease.

Robert Alexander Fraser, New York; Trinity Medical College, Toronto, Ont., Canada, 1903; became medical director in 1913 of the New York Life Insurance Company, serving as chief medical director from 1934 to Sept. 1, 1945; past president of the Association of Life Insurance Medical Directors; died in Greenwich, Conn., November 1, aged 67, of heart disease.

John Philip Greene, Larchmont, N. Y.; Bellevue Hospital Medical College, New York, 1896; served as health officer and police and fire surgeon in Mamaroneck; died in the Grasslands Hospital, Valhalla, November 4, aged 71, of congestive heart disease.

Alice Alloway Hand, Cleveland Heights, Ohio; Western Reserve University School of Medicine, Cleveland, 1944; interned at the Metropolitan Hospital in New York; died in a hospital at Columbus October 30, aged 26, of Hodgkin's disease.

George Arthur Hawkins-Ambler, San Francisco; L.R. C.P., Ireland, 1885 M.R.C.S., England, 1889 and F.R.C.S., Edinburgh, Scotland, 1891; died in the San Francisco Hospital October 25, aged 83, of cerebral hemorrhage and arteriosclerotic heart disease.

Joseph Paul Hennerich Jr., St. Louis; Washington University School of Medicine, St. Louis, 1913; died October 16, aged 61, of coronary thrombosis.

Andrew Jackson Kellam, Canton, Texas; Baylor University College of Medicine, Dallas, 1913; died October 23, aged 65, of heart disease.

John Randal Knight, Eddy, Texas; Vanderbilt University School of Medicine, Nashville, 1893; for many years local bank president; died October 29, aged 77, of generalized arteriosclerosis.

Eugene Ross Linklater ⊕ Kenmore, N. Y.; University of Buffalo School of Medicine, 1905; served during World War I; health officer; formerly school physician; died in the Millard Fillmore Hospital, Buffalo, October 18, aged 62, of cerebral hemorrhage.

Ross George Loop ⊕ Elmira, N. Y.; University of Buffalo School of Medicine, 1897; fellow of the American College of Surgeons; served during World War I; during World War II in charge of the emergency medical division for civilian defense in Chemung County and associated with the Procurement and Assignment Service; consulting surgeon at the Arnot-Ogden and St. Joseph's hospitals in Elmira and Tioga County General Hospital in Waverly; died October 19, aged 69, of arteriosclerosis and heart disease.

Donald Leo Maddox, Philadelphia; Temple University School of Medicine, Philadelphia, 1917; died in the Norristown (Pa.) State Hospital September 2, aged 56.

Martin Teasley Maxwell, Robbinsville, N. C.; Southern Medical College, Atlanta, 1885; died in the Angel Hospital, Franklin, October 15, aged 85, of influenza and heart disease.

Charles W. Merkel, Ann Arbor, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905; also a graduate in pharmacy; died in Harriman, Tenn., October 28, aged 75, of angina pectoris.

Robert Hyndman Miller, Haleyville, Ala.; Chattanooga (Tenn.) Medical College, 1902; member of the American Medical Association; died October 17, aged 71, of carcinoma of the intestine.

Arthur T. Monismith ⊕ Fort Lupton, Colo.; Denver and Gross College of Medicine, 1904; died in St. Luke's Hospital, Denver, September 27, aged 65, of cerebral hemorrhage.

Harry Alfred O'Neal, Brookville, Pa.; University of Pittsburgh School of Medicine, 1911; died in the Warren (Pa.) State Hospital September 20, aged 59, of cardiorenal disease and diabetes mellitus.

Joseph Alexander Pinckard, Minneapolis; Missouri Medical College, St. Louis, 1896; died in the Kahn Memorial Hospital, Marshall, Texas, October 14, aged 75, of coronary occlusion.

Charles Teed Pollard ⊕ Montgomery, Ala.; Medical Department of Tulane University of Louisiana, New Orleans, 1897; member of the American Medical Association; served during the Spanish-American War and World War I; died in the Hubbard Hospital November 4, aged 73, of amebic dysentery.

Aba Reiss, Philadelphia; Medizinische Fakultät der Universität Wien, Vienna, Austria, 1901; died in St. Luke's and Children's Medical Center September 2, aged 67, of coronary occlusion.

Harold Fuller Sawyer ⊕ Pleasant Ridge, Mich.; Detroit College of Medicine and Surgery, 1927; interned at the Grace Hospital in Detroit; began active duty as a lieutenant commander in the medical corps of the U. S. Naval Reserve on Dec. 18, 1942; service terminated Aug. 26, 1943; on the staffs of the Grace and Woman's hospitals in Detroit; died October 8, aged 43, of coronary thrombosis.

Bernhard Harvey Schmidt ⊕ Davenport, Iowa; Rush Medical College, Chicago, 1897; life member of the Iowa State Medical Society; past president of the Scott County Medical Society; formerly city physician; served on the staff of the Mercy Hospital, where he died October 18, aged 70, of coronary thrombosis.

Mary Dorothea Skinner, Seattle; University of Oregon Medical School, Portland, 1903; died October 20 of exhaustion and hemiplegia.

Herbert Leonel Taylor ⊕ Portsmouth, N. H.; Jefferson Medical College of Philadelphia, 1902; fellow of the American College of Surgeons; past president of the Portsmouth Medical Society, Rockingham County Medical Society and New Hampshire Medical Society; bank director; member and past president of the staff of the Portsmouth Hospital; consulting surgeon, York Hospital, York Village, Maine; died October 24, aged 68, of brain tumor.

Frederick William Van Lengen, Syracuse, N. Y.; Syracuse University College of Medicine, 1898; member of the American Medical Association; served as demonstrator of anatomy at his alma mater; on the staff of the People's Hospital; for many years physician for the Syracuse University football teams; served as president of the alumni association of the Syracuse University College of Medicine; died October 15, aged 71, of coronary occlusion.

Joseph Clinton Vaughan, Rich Square, N. C.; Medical College of Virginia, Richmond, 1915; member of the American Medical Association; served during World War I; died in the Duke Hospital, Durham, October 13, aged 56, of chronic nephritis.

Robert Mayhue Ware ⊕ Fitzgerald, Ga.; University of Georgia Medical Department, Augusta, 1902; medical director of the Fitzgerald Hospital; died October 23, aged 68.

John B. Weston, Hemet, Calif.; University of Pennsylvania Department of Medicine, Philadelphia, 1878; served as mayor of Hemet and member of the city park commission; honorary park commissioner; in recognition of his philanthropy and interest in beautifying the community, the city council named the park in his honor; at one time health officer of Duluth, Minn.; died September 7, aged 91, of carcinoma of the gallbladder.

Adam George Youngman ⊕ St. Louis; St. Louis University School of Medicine, 1912; on the staffs of St. Anthony's Hospital and the Lutheran Hospital, where he died October 20, aged 65, of coronary thrombosis.

DIED WHILE IN MILITARY SERVICE

Charles John Allen ⊕ *Lieutenant Commander, U. S. Navy,* Milwaukee; Marquette *University School of Medicine,* Milwaukee, *1939; interned at the Milwaukee Hospital;* entered the U. S. Navy *as a lieutenant (jg) in* July 1940; served *as surgeon aboard a destroyer for twenty-two months; transferred to the Naval Hospital in* Corona, Calif.; died Feb. 1, 1944, aged 31, as the result of ship collision at sea while attached to the U. S. S. *Washington.*

John Newton Dunn ⊕ Blackstone, Va.; Medical College of Virginia, Richmond, 1931; at one time associated with the Civilian Conservation Corps in the West; began active duty as a captain in the medical corps, Army of the United States, on March 11, 1942; promoted to major; served as chief surgeon with a fighter group in England and Russia; died in England Sept. 3, 1945, aged 43, of coronary occlusion.

Victor Gang, New York; Rush Medical College, Chicago, 1937; interned at the University of Chicago Clinics in Chicago and Lenox Hill Hospital; served a residency at the Murray Hill Hospital; began active duty as a lieutenant (jg) in the medical corps of the U. S. Naval Reserve on Feb. 9, 1941; promoted to lieutenant and lieutenant commander; drowned in the Philippine Islands Sept. 3, 1945, aged 32.

Abraham Gellman, Brooklyn; Long Island College of Medicine, Brooklyn, 1940; interned at the Montefiore Hospital for Chronic Diseases in New York and the Kings County Hospital in Brooklyn, where he served a residency; began active duty in the medical corps, Army of the United States, as a first lieutenant on Aug. 22, 1942; later promoted to captain; died in Luzon Feb. 11, 1945, aged 28, of injuries received when his gun accidentally discharged.

Joseph Rawlins Ginther ⊕ Norristown, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1929; member of the American Medical Association; interned at the Homeopathic Medical and Surgical Hospital and Dispensary in Pittsburgh; began active duty as a lieutenant commander in the medical corps of the U. S. Naval Reserve on Dec. 21, 1942; stationed at the 12th Naval District base in San Francisco; died July 1, 1945, aged 41, of acute cirrhosis of the liver.

Joseph Nash, New York; University and Bellevue Hospital Medical College, New York, 1926; member of the American Medical Association; fellow of the American College of Surgeons; specialist certified by the American Board of Surgery; assistant professor of clinical surgery at his alma mater, now known as the New York University College of Medicine; on the staff of the Bellevue Hospital; house physician at the Hotel Plaza; author of "Surgical Physiology," a textbook published in 1942; commissioned a first lieutenant in the medical reserve corps of the U. S. Army on June 9, 1926; began active duty in the same rank on Aug. 1, 1941; assistant chief of the surgical service in the Lovell General Hospital in Fort Devens, Mass.; promoted to captain and major in the medical corps, Army of the United States, in 1942; in December 1943 went overseas with the rank of lieutenant colonel; appointed chief of the surgical service of the Ninetieth General Hospital in England; arriving in Normandy early in the invasion of Europe, served as a surgical consultant of the 819th General Hospital and as surgical chief of the Ninetieth General Hospital Unit; died in Germany Nov. 8, 1945, aged 43, of injuries received in an aircraft accident.

Jan. 12, 1946.

London's War Ordeal: Comparison of Vital Statistics with Those of New York

The report on the health of the county of London for 1944 has just been published. The term "county of London" applies only to the inner half of the metropolis, which is administered by the London County Council. The population of greater London exceeds 8 million, but that of the county was only a little over 4 million in the last prewar year of 1918. During the war it fell to 2½ million. For the first time since the outbreak of the war, population statistics have been allowed to be published. Mothers, children and hospital patients were evacuated to safer districts as the attack developed. The total number of civilians killed in London during the war was 17,811. In spite of the ordeal of bombing, the health rate in 1944 remained satisfactory. The birth rate was 18.1 and the death rate 16.7 per thousand. The infant mortality was 51 per thousand live births. Before the war there were 814,498 dwellings. Of these 709,518 were affected by the bombing, about 70,000 were completely destroyed and 56,000 were rendered uninhabitable and 66,000 seriously damaged. The London ambulance service conveyed to hospitals or first aid posts 46,709 persons injured by bombing. During the war there were 660 bombing incidents at the County Council's 100 hospitals, of which 17 had to be evacuated. Out of a total of 1,200,000 patients admitted during the war period 257 were killed in air raids and 5,000 hospital beds were destroyed.

The report makes an interesting comparison between the vital statistics of London and of New York. The population of New York is about a million less than that of greater London but about thrice that of the county of London. The birth rate of London in 1944 was 18.1 against 16 in New York. In London the death rate was about 50 per cent higher and the infant mortality 70 per cent higher than in New York. The maternal mortality was about the same for the two cities. Diphtheria is on the decrease in both cities, but, allowing for difference of population, the disease is fifteen times more prevalent in London. The mortality from appendicitis is nearly the same. In London cancer mortality is about 40 per cent higher. The mortality from diabetes in London is only 25 per cent of that in New York, from cancer about 40 per cent higher, from pulmonary tuberculosis about twice and from other forms between three and four times that in New York.

The European Drug Trade

During the war the importation of large quantities of German drugs ceased, and British manufacturers produced the more important ones. Seven of the large British firms which manufacture drugs have formed a company which hopes to supply 200 million new customers on the European continent formerly supplied by the German chemical trust I. G. Farbenindustrie. The new firm is the British-European Pharmaceutical Company, Ltd. Besides supplying Europe with the products marketed before the war, the British company will export many new drugs produced during the war by British chemists.

The Diagnosis of Cancer

In the House of Commons Mr. Somerville Hastings, laryngologist, asked the minister of health to provide lectures for general practitioners on the early recognition of cancer. He stated that there are about 70,000 deaths annually from cancer and that a large proportion of cancer patients obtain specialist treatment too late. Mr. Hastings reported that where such lectures have been instituted they have been much appreciated and well attended by general practitioners. Mr. Aneurin Bevan, minister of health, replied that the purposes sought by Mr. Hastings could perhaps be best attained by encouraging early and frequent consultations between general practitioners and specialists in the work of diagnosis and treatment. Organized arrangements are now being developed under the Cancer Act of 1939 as far as present circumstances permit.

THE NETHERLANDS

(From Our Regular Correspondent)

AMSTERDAM, Jan. 20, 1946.

War Sequels

The Netherlands of 1940 were thoroughly organized, well equipped with most necessities and, in comparison with other European countries, at a high level of social well being. There were nearly 9 million inhabitants, with a good average education. Ten universities and high schools provided professional education and information in science. Modern industries kept their staffs in touch with improvements. In the war large parts of cities and towns were destroyed, among them the Hague, Rotterdam, Groningen, Arnhem, Middelburg, Nijmegen, Vlissingen and Venlo, either by action or by attempts to transform these places into strongholds, with tank traps and fortifications stretching across densely populated urban districts. This involved evacuation or death of the inhabitants and destruction of their possessions and dwellings. In addition, many hundreds of houses at Amsterdam and elsewhere were exposed to destruction by deporting people and confiscating their possessions. During the winter of 1944-1945 the wooden parts of these houses were pulled down for fuel until the walls collapsed. Industries were robbed of machines and tools, libraries of books, institutes of their instruments. Higher education was disorganized by the dismissal and imprisonment of teachers or by inviting the students into Nazi organizations, which membership more than 80 per cent refused. As a result of this attitude they were deported to Germany for forced labor or sent to concentration camps, where many of them perished miserably. Other actions against intellectual life were too numerous for a short description. Most periodicals were curtailed so that they ceased to be sources of information. Food rations steadily decreased from 1,842 calories per person in 1941 to 1,480 calories in 1944. In the western provinces, whose liberation was delayed till May 1945, the rations dropped rapidly during the last year to 420 calories despite Red Cross aid from Sweden, Switzerland and Portugal. Conditions were disastrous at the date of liberation, adding starvation disease to others then already prevalent. Deliberate starvation inflicted on the country, rather than military action, increased the loss of life. Casualties due to all causes including land, sea and air action amount to above 200,000, or more than 22 persons per thousand inhabitants.

Recovery of urban life has advanced spectacularly since the liberation. Rations are back to 2,150 calories by now and light, gas and fuel are almost adequate, thanks to an exceptionally mild winter. Transport performed miracles with terribly depleted material; during the last months of German occupation even the electrical leads which supplied an important part of the railway system were pulled down.

But we are still lamentably handicapped. Our students, anxious to learn and to catch up, do not have modern textbooks; we still need periodicals, books and references to work done or in progress in the free world during the war. By private initiative a few workers were able to gain access to scientific literature, but the majority are still starving for information. It would be a fitting gesture to give our scholars literature and appliances in the hope of future financial adjustments with reinstatement and intensification of intellectual intercourse. Many promises have already appeared in our public press suggesting satisfactory conditions to the man in the street, but for the scholar himself but little has materialized.

Anniversary of Amsterdam University

January 8 was the 314th anniversary of the founding of Amsterdam University, celebrated in the great hall by a public meeting. Woerdeman, professor of anatomy, read a paper on the present state of the study of embryonic induction. On the same occasion two honorary doctor degrees were awarded; one of them—in medicine—was conferred on Elisabeth Dingemanse of the pharmacotherapeutic laboratory in recognition by the Faculty of Medicine for her research on insulin, sex and hypophysial hormones and the detection of nicotine: its chemistry, purification and assay by colorimetry and chromatography. A degree *honoris causa* in medicine is highly exceptional at our university, indicating a reward for keen and expert work.

In December 1945 the Leiden hygienist Professor P. C. Flu died at the age of 64. He was known as an authority on tropical bacteriology and hygiene. His son was killed by the S. S. in a Leiden street while visiting patients two years ago.

The chair of biochemistry of Utrecht University was awarded to H. G. K. Westenbrink, biochemist conservator of Amsterdam University.

BOLIVIA

(From Our Regular Correspondent)

La Paz, Jan. 5, 1946.

The Rockefeller Foundation in Bolivia

In May 1932 a devastating yellow fever epidemic flared up in Santa Cruz, which is a vital center of communications between the east and the west of the country. The Rockefeller Foundation, working then in the Chanaan Valley in Brazil on a similar problem, was asked for help. Two American physicians, Dr. Soper and Dr. Walcott, were sent by the health division of the foundation to La Paz. There had been 50 deaths due to yellow fever in Santa Cruz when Dr. Walcott started his work by organizing a training center for the fight against the Aedes aegypti mosquito, which infested all the dwellings in Santa Cruz. So successful was the foundation that the last yellow fever case in Santa Cruz was registered in August 1932, only two months after work was begun. The origin of that epidemic was later traced to a case of imported jungle yellow fever.

The anti-Aedes campaign was not limited to Santa Cruz alone but was soon extended to thirteen smaller places; viscerotomy services were started to provide liver specimens from the dead. As the result of the work done by the foundation, Santa Cruz is today practically free from any kind of mosquitoes, a grave menace before. A yellow fever case has not been reported there since 1932.

Another dangerous yellow fever epidemic was reported in 1936 from the tropical districts Beni and Pando, in the north of the country in the valley of the Amazon. Some 1,300 cases were diagnosed and 56 deaths were traced to that disease after examination of liver specimens. Other hundreds of deaths were probably due to yellow fever, but definite diagnosis could not be established, as liver specimens could not be secured because of the lack of communications and other difficulties. The epidemic area was a large one, extending to the western border of the Cordilleras to altitudes of 500 meters above sea level.

In the Yungas region near La Paz, several smaller epidemics were registered between 1939 and 1942. Another outbreak occurred in Todos Santos, the last river port, reached by boat in the journey up the Amazon and its tributaries. As soon as these outbreaks became known, the Rockefeller Foundation immediately sent personnel to eliminate Aedes aegypti and to establish viscerotomy centers and other services. Vaccinations against yellow fever were started in 1938, and by now over 34,000 people in exposed areas have been vaccinated. Aedes aegypti is actually not found in any of the towns of this country. A constant control is exercised and the viscerotomy service has extended to sixty-five places; liver specimens are sent to the central field laboratory of the foundation at Santa Cruz. Vaccination teams are constantly visiting the exposed areas, and every launch coming up the rivers is inspected and fumigated. Results are striking: there are hardly any yellow fever cases registered.

The National Health Department suggested in 1942 that the foundation should provide services also for malaria and ancylostomiasis, endemic diseases affecting an estimated 50 per cent of the total population in large territories of Bolivia. The foundation took charge of this problem. In the fertile valleys near La Paz work was difficult because of the constant menace of malaria; pseudopunctipennis was found to be the vector in some places even up to 2,600 meters above sea level. In 1943 the foundation started a large scale program there as well as in the valleys of Cinti and Mizque. Two health centers were established and staffed with physicians and nurses, free drugs were distributed and sanitation work was started to eliminate mosquito breeding places. The work was most successful. After only two years many places are practically mosquito free.

In the valley of the tributary streams of the Amazon, the foundation is fighting widespread ancylostomiasis. A survey made among school children there showed that many of them are hosts for one or several intestinal parasites; 80 per cent have ancylostoma, and the average hemoglobin value is as low as 50 per cent. It is in these regions that most of Bolivia's rubber is produced, and a surplus of farming products could be produced if there were enough healthy laborers. The foundation started a house to house survey to teach the necessity of individual sanitation in every dwelling. It aided in the construction of adequate lavatories and maintained free dispensaries.

The chairman of the foundation (Special Service of Prophylaxis against Yellow Fever, Malaria and Uncinariasis) is Dr. Henry P. Carr, an American physician who has worked in Bolivia since 1942; previously he had been stationed in Cuba, Mexico and Peru. He is assisted by a fairly large staff of Bolivian physicians, nurses and other sanitation personnel; specialists in sanitary problems are called from the United States whenever needed. A training center is in operation to provide the necessary personnel. The work of the several dispensaries is most satisfactory; sixty-nine viscerotomy posts are operated all over the tropical districts. Sanitation work in several areas has been successfully completed. A large scale educational program for children and adults is in operation.

Marriages

Ralph Burk Dawson, St. Louis, to Miss Nancy Scott Causey of Greensboro, N. C., in New York, November 22.

Bedford F. Boylston, Aiken, S. C., to Miss Isabel Brickley, Merchantville, N. J., in London, England, December 10.

Joseph Theodore Andrews, Harlan, Ky., to Miss Alice Charlotte Merry at Delphos, Ohio, December 15.

John Thomas Goodgame, Chattanooga, Tenn., to Miss Elizabeth Wilder of Clearwater, Fla., December 26.

Ralph DeCicco, Des Moines, to Lieut. Therese Ingrato, WAC, of Green Island, N. Y., December 11.

Frederick Fletcher Adams Jr., Columbia, S. C., to Miss Doris Marcia Gruber in Charleston recently.

Gray Carroll Buck Jr. to Miss Darthula Hardie Hendrick, both of Birmingham, Ala., November 15.

Mark W. Dick to Dr. Louise F. Schnute, both of Grand Rapids, Mich., in December.

Correspondence

IMPORTANCE OF RH FACTOR

To the Editor:—In The Journal, Dec. 29, 1945 I note the communication from Dr. Ralph Luikart in which he states that for almost a year he has instituted the determination of the Rh factor on his obstetric patients and that in the last six months he has been doing so routinely.

I wish to state that I have instituted this method in my own office for almost two years and in my service at the Beth-El Hospital for the past year and a half. I brought this to the attention of the Brooklyn Gynecological Society in a paper, "The Rh Factor in Obstetrics," which was published in the *Journal of Obstetrics and Gynecology* of September 1945. In that paper I called attention to the fact that in certain communities the Rh factor determination is more important in the saving of infant lives than is the Wassermann test. In a review of over 5,000 charts I did not encounter a single case of syphilis or a positive Wassermann reaction and yet, according to the state law, it was done routinely. I then urged that the Rh factor determination in all pregnant women be made as mandatory as the Wassermann test and I am glad to see the statement of Dr. Luikart that the Nebraska State Health Department is offering that service free.

I am sure that the time is fast approaching when it will be made a routine in all states where the Wassermann test is demanded.

Jacob Halperin, M.D., Brooklyn.

BLOOD GROUPING TESTS IN INFANCY

To the Editor:—I wish to endorse Dr. Edgar's suggestion (The Journal, January 12, p. 107) that Dr. Harville (*ibid.*, Nov. 17, 1945, p. 801) check the blood grouping tests in the family where he found a mother of group AB and a child of group O, and that the result be published in The Journal. This may forestall a great deal of trouble for those who are called on to testify in courts in cases of disputed paternity. It is possible that two factors may have contributed to the erroneous result in Dr. Harville's case (and erroneous it will no doubt turn out to be): The mother may be AB, subgroup A_2B, and the child will then be A_2, a subgroup in which the red cells are agglutinated less readily than in subgroup A_1, especially in the newborn. That is the reason why it is recommended not to do blood grouping tests in infants less than 1 month of age.

To this may be added the relatively large amount of transfused blood of group O, which, being Rh negative, remains in the circulation for a considerable time and thus may make the detection of the infant's own group A that much more difficult. In some cases of severe hemolytic anemia of the newborn the transfused blood may be the only one present in the circulation for some time until the infant begins to produce its own red cells.

Israel Davidsohn, M.D., Chicago.

KETOSURIA AND KETONURIA

To the Editor:—The Journal of Oct. 6, 1945 has just come to hand and I have read with much interest the editorial on ketosis on page 448. I notice that the term "ketosuria" is used to mean excretion of ketones in urine. I do not know if this term is commonly so applied in the United States, but it seems to me liable to cause confusion. I suggest that "ketosuria" should be reserved to mean the presence of ketoses (usually fructose) in urine and that the term "ketonuria" should be used to mean the presence of ketones in urine.

James C. Eaton,
Victoria Infirmary,
Glasgow, Scotland.

"PAROXYSMAL ABDOMINAL PAIN"

To the Editor:—Referring to the comment anent the article "Paroxysmal Abdominal Pain" published in the December 29 issue of The Journal, I submit the following:

In none of the 6 cases reported was there any specific mention made that a definite allergen was the causative factor which precipitated the attacks of abdominal pain. In the first case it was clearly stated that the author believed "the original injection of diphtheria antitoxin had produced an angioneurotic edema of the brain with subsequent changes in the cerebral cortex which predisposed to abnormal cerebral discharges." This patient had been studied by several prominent allergists, had been given the gamut of the usual tests and had been placed on various diets, all to no avail. Were there a specific allergen operative in the production of this patient's seizures, they certainly would have continued after treatment with anticonvulsants as well as prior to therapy. The latter applies as well to the remaining cases. Cases 2, 4, 5 and 6 had the usual studies for allergens, which yielded no positive data.

I do not mean to imply by this, however, or by the cases reported, that allergies may not produce the type of abdominal epilepsy which I have described. I agree that an allergic basis may be the substratum in some cases, and Winkelman and Moore have reported abdominal pain occurring as a partial epileptic manifestation in patients responding to certain allergens (Allergy and Nervous Diseases, *J. Nerv. & Ment. Dis.* **93:**736 [June] 1941).

With respect to the suggestion that metrazol be used to precipitate an attack, may I say that I believe the evidence as given in the detailed history was sufficient to fall within the criteria outlined for the convulsive state. Furthermore, metrazol might produce only a motor epileptic display without sensory abdominal representation. Having had considerable experience with the convulsive seizures induced by metrazol, I would feel very reluctant to submit my patients to such a drastic test when the history, examination, electroencephalographic studies and response to anticonvulsant therapy have, I feel, amply demonstrated the nature of the disorder.

Matthew T. Moore, M.D., Philadelphia.

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in The Journal, Feb. 9, page 372.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Part III. Various Centers, March. Exec.-Sec., Mr. E. S. Elwood, 225 S. Fifteenth St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Dermatology & Syphilology: *Written. Group B.* April 22. *Oral. Group A and B. June 6-8.* Final date for filing application is March 1. Sec., Dr. George M. Lewis, 66 E. 66th St., New York 21.

American Board of Internal Medicine: *Oral.* Philadelphia, May 9-11. Final date for filing application is March 15. San Francisco, June *27-29*. Final date for filing application is April 15. Asst. Sec., Dr. W. A. Werrell, 1 W. Main St., Madison 3, Wis.

American Board of Ophthalmology: Chicago, Oct. 9-12. Sec., Dr. S. Judd Beach, 56 Ivie Rd., Cape Cottage, Me.

American Board of Otolaryngology: *Chicago, May 22-25.* Sec., Dr. Dean M. Lierle, University Hospital, Iowa City, Ia.

American Board of Pediatrics: *Written.* Locally, March 22. *Oral.* Cleveland, April *27-28* and *San Francisco, July 1-5.* Sec., Dr. Lee F. Hill, 3309 Forest Ave., Des Moines, Ia.

American Board of Psychiatry & Neurology: Chicago, May 24-25. Final date for filing application is February 1946. Sec., Dr. Walter Freeman, 1028 Connecticut Ave., N. W., Washington 6, D. C.

American Board of Surgery: *Written. Part I.* Various centers, October. Final date for filing application is July 1. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia 2.

American Board of Urology: *Oral.* Chicago, *February 1947.* Final date for filing application is Nov. 15. Sec., Dr. Gilbert J. Thomas, 1409 Willow St., Minneapolis 4.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Uterine Tumor Mistaken for Pregnancy.—The patient, a divorcee, had some irregularity in her menses and excessive flow and pain when they occurred. Dr. Deppen, a specialist in internal medicine, whom she consulted, made a diagnosis of pelvic tumor. Determining that an operation was necessary and since he did no surgery, he referred the case to Dr. Johnson, who operated, March 2, 1938, while the patient was "flowing," removing, however, only a diseased appendix. Apparently, prior to the operation, Johnson, suspecting pregnancy, disagreed with the diagnosis made by Deppen. He did not inform Deppen of his disagreement and Deppen was not present at the operation. Later Johnson advised the patient, her sister and Deppen that the patient was pregnant. About two weeks later a Friedman test, made at Deppen's suggestion at the hospital at which the patient was confined, had a positive reaction, indicating pregnancy. The patient left the hospital three weeks after the operation. She continued to have pain and uterine hemorrhages. On March 28 Deppen referred the case to Dr. Harvey, a specialist in obstetrics and gynecology, who examined her over a period of three weeks. The Friedman test, among others, was made, with a negative result. Nevertheless, Harvey was uncertain as to whether the patient's condition was one of pregnancy or of uterine tumor. He waited and applied other tests on the theory that the uterus, if a fetus was present, would increase in size; but the uterus did not so increase, and a second Friedman test was negative. The hemorrhages increased, and Harvey operated. On visual examination the uterus did not contract on stimulation and was "paler" than usual for a pregnant uterus. To him this indicated a tumor and that even if a fetus was present it was not alive. Accordingly, believing it necessary to save his patient's life, he removed the uterus. Examination of the organ by a pathologist revealed the presence of an "inside" tumor, even though, in his opinion, the uterus had "the [outward] appearance and consistency of a pregnant uterus."

Subsequently Dr. Johnson died and the patient brought suit for damages for malpractice against his administratrix. The gist of the action was that while Johnson was employed to remove the "tumor or abscess" in the uterus, without the patient's knowledge or consent, he removed her appendix and, "disregarding the tumor or abscess then present in plaintiff's body, failed and neglected to remove said tumor abscess" and thereby the plaintiff was caused to have a second operation. The action was further based on an allegation that Johnson negligently and falsely stated to other persons that the patient, an unmarried woman, was pregnant. At the trial the patient testified that she first saw Johnson the afternoon before the operation, when he came to her hospital room, removed the sheet covering her body, placed his hand on her abdomen and said "We will operate for a tumor." The entire examination covered two or three minutes and Johnson, so she stated, made no further examination or tests and took no history. There was introduced in evidence certain portions of her hospital records. One of these was referred to as the "summary" record, was signed by Johnson, and contained the following notations, among others:

> Under the title of "Chief Complaint" . . . "Severe pain pelvis. Vaginal discharge. Occasionally blood in discharge. Unable to work. Constipated; has had no regular normal flow for several months"; under "Onset and Course" the following: "Has had discharge for several months. Bartholin gland abscess opened and drained. Last two weeks increased pelvic pain with increased flow at periods and considerable discharge"; and under "Physical Examination" the following: "Abdomen: Upper Tympanitic. Lower, rigid and painful in right lower quadrant. Rounded mass, mid line, reaching nearly the umbilicus. Considerable vaginal discharge. No Blood."

Another record introduced was entitled the "Record of the Operation" and was also signed by Johnson, showing a "Preoperative" diagnosis of "Appendicitis sub-acute. Pregnancy? Pelvic adnexal disease." His "Postoperative Diagnosis" entry was "Ditto" written under "Pelvic adnexal disease," followed by "Pregnancy—4 mo. Appendicitis s. a." His "Gross Pathology" entry was "Pregnant uterus 4 mo. appendix—deeply injected adherent to rt. ovary region." It further shows "Operation" followed in writing by "Appendectomy." The "Summary" record showed under "Preliminary Diagnosis" the same entries recited and under "Final Diagnosis" was recited "Appendix sub acute. Pregnancy 4 to 4½ mos. Pelvic adnexal dis." and following the printed words "Indications for Operation" was the entry "Appendix acute. Pelvic adnexal disease. Pregnancy (?) suspected." From the evidence it further appeared that when Johnson operated "there was no emergency requiring an immediate operation." There was also introduced the testimony of expert medical witnesses that where a diagnosis of pelvic tumor is made and there is a suspected pregnancy, as there was here, several tests should be made and that question determined before an operation is undertaken. Failure to do that would be carelessness and negligence on the part of the surgeon. The evidence of the experts was further that ordinary preoperative tests can determine whether or not a pregnancy exists; and that where there is no emergency and the surgeon disagrees with the diagnosis of the referring physician, and does not know what tests the referring physician has made, nor what those tests indicated, the surgeon should make the tests and examinations or have them made and know the results before operating. Further, the medical witnesses agreed that neither the Friedman test, nor menstruation or the lack of it, are infallible indications. There are tests, however, which the surgeon should have made and taken into consideration in arriving at his ultimate conclusion. At the close of the evidence the trial court refused to direct a verdict for Johnson's administratrix and the jury returned a verdict for the patient, on which judgment was entered. An appeal to the Supreme Court of Nebraska eventuated.

To determine the liability of the operating physician under the present circumstances the court discussed applicable principles of law and summarized them somewhat as follows: Where a patient's physician informs a surgeon of the diagnosis which the physician has made and, with the authority of the patient, employs the surgeon to perform an operation which the physician deems advisable or necessary, the surgeon may rely on the diagnosis of the physician and is not required to make an independent diagnosis before operating, in the absence of information or conditions which would put the surgeon on inquiry as to the correctness of the physician's diagnosis and the advisability or necessity for the operation. Where, under the aforementioned conditions of employment, the surgeon, relying wholly on the physician's diagnosis, operates and during the course thereof discovers facts or conditions which suggest a reasonable basis for a different conclusion from that arrived at by the physician, which, if true, would make the proposed operation inadvisable or unnecessary, and there exists no emergency requiring him to proceed, the surgeon is not negligent if he refrains from completing the operation until a further proper diagnosis based on the newly discovered facts or conditions is made, and a proper course of action based thereon is determined. Likewise, where, under the foregoing conditions of employment, and before performing the operation, the surgeon discovers facts or conditions which appear to contradict the physician's diagnosis, or which cause the surgeon to question the correctness of the physician's diagnosis or to reach a different diagnosis, with the result that a different or no operative treatment is indicated, and there is no emergency, and the surgeon operates without making an additional and proper diagnosis to determine the questions presented and the action to be taken, the surgeon is negligent and liable to respond in damages for such injury and detriment to the patient as proximately follows.

The court accordingly believed that the trial court did not err in refusing to direct a verdict in favor of the surgeon's administratrix.

However, the Supreme Court found it necessary to reverse the judgment of the trial court and to remand the cause for further proceedings because of certain errors committed by the trial court In the first place, the trial court in instruction No. 1 to the jury set out plaintiff's allegation of negligence that "During the operation, and without the previous consent and without the knowledge of the plaintiff, the defendant (Dr. Johnson) removed her appendix." In his instruction No. 3 he advised the jury of plaintiff's burden of proving that Dr. Johnson was "negligent in his treatment of the plaintiff in *some particular* as alleged in the petition," and that "If plaintiff has proved the above propositions by a preponderance of the evidence and that the *one or more* of them was the proximate cause of said damage to the plaintiff, then and in that case you will find for the plaintiff." There is no evidence, said the Supreme Court, that plaintiff consented to the removal of her appendix or that it was done with her knowledge. The evidence is all to the contrary. The evidence of Dr. Deppen, however, is that Dr. Johnson, finding the condition of the appendix as he did, should have removed it, and it was right that he did. There is no evidence to the contrary. Moreover, there is no evidence that the removal of the appendix in any wise caused any of the damage for which plaintiff sought to recover. That issue should not have been submitted to the jury. There is no way by which it can be determined here what, if any, part of the verdict was given based on the removal of the appendix. We deem the error to be prejudicial.

In the second place, the trial court submitted to the jury that "During said operation defendant (Dr. Johnson) examined and handled the uterus and saw, or by the exercise of ordinary care and skill would have ascertained the condition of the uterus as it was, affected with said tumor or abscess." We find, said the court, no evidence that Dr. Johnson "handled the uterus." Neither is there evidence that, *after* he had exposed the uterus, he could "by the exercise of ordinary care and skill" have ascertained that the uterus was affected with a tumor. The test of stimulation that could then have been made with the uterus in place was admittedly inconclusive. The evidence of plaintiff's experts, however, was that to make a definite diagnosis after the uterus was exposed would have required that it be opened, as was done in the laboratory, and that that could not be done in place without grave danger to the plaintiff. When he had proceeded that far, Dr. Johnson was confronted with either removing a uterus which he believed contained a fetus, with the resulting death of the fetus if alive, and the sterility of the plaintiff, or leaving the uterus in place. He elected not to proceed. The expert witnesses of plaintiff do not indicate other than that he proceeded in the exercise of a proper professional judgment at that time. We are of the opinion that the trial court erred in submitting this instruction to the jury and that it was prejudicial.

Thirdly, in instruction No. 2, the trial court "summarized" to the jury the claim of the patient as follows: "Plaintiff claims that the physician and surgeon was careless and negligent in advising an operation without sufficient examination and in performing said operation improperly, and that said negligence and carelessness was the direct and proximate cause of plaintiff's damages" Dr. Johnson did not advise an operation. He performed one and, according to the evidence, without sufficient examination and diagnosis The instruction refers to the "physician and surgeon," who, it is claimed, "was careless and negligent in advising an operation." Dr. Deppen advised the operation. He was not a party to the action, nor is it claimed that he was negligent or careless. The effect of the instruction was to wipe out the specific recital of plaintiff's claims and to submit to the jury "to consider" an inaccurate and misleading summary. The instruction should not have been given and was in our opinion prejudicial to the defendant.

As stated before, the judgment in favor of the patient was reversed and the cause remanded for further proceedings —*In re Johnson's Estate: Douglas v. Johnson, 16 N. W. (2d) 504 (Neb., 1944).*

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

Following are abstracts of stipulations in which promoters of "patent medicines," medical devices or cosmetics have agreed, following action by the Federal Trade Commission, to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products. These abstracts are given as examples, since space does not permit a review of all cases reported.

Konceal Hair Dressing.—That this product, formerly called simply "Konceal," is a hair dressing and not a dye, will restore the original color to the hair, dissolve dandruff, conceal the age or give a youthful appearance, were among the misrepresentations which the Germadol Herb Company, New York, agreed to discontinue in a stipulation signed in July 1944.

La-Nu Liquid Shampoo and La-Nu Medicated Ointment.—The Powell Distributing Company and the La Nu Distributing Company, Philadelphia, stipulated in July 1944 to cease representing that the shampoo gives new life or added vitality to the hair, or that the ointment assures a healthy scalp.

Murray's Skin Bleach.—Murray's Superior Products Company, Chicago, stipulated in April 1944 to cease representing, among other things, that this clears normally dark skin, blotches or pimples, and to warn in advertisements and labeling that directions must be followed.

Nature's Aids Center Nostrums.—Nature's Aids Center, Brooklyn, stipulated in July 1944 that it would cease representing: That "Karpatol" will cure any stomach ailment, promote digestion or benefit the blood, liver, kidneys or nerves; that "Regulator Femina" will regulate the menses or help during the menopause; that "Holly (or Holy) Mountain Tea" will relieve or cure any chest or lung disease, or has been tested and recommended by universities or other institutions, or that "Garlo Garlic Pills" will relieve symptoms of high blood pressure.

New Peruna Tonic.—That this will cure colds or build resistance to them, restore energy, increase weight or vigor, or affect such conditions other than as a tonic were among the misrepresentations to be discontinued in the advertising, as stipulated in April 1944 by the Consolidated Drug Trade Products, Chicago

Nix Bleach Cream.—The Nix Cosmetics Company of Memphis, Tenn, stipulated in September 1944 to discontinue any advertisement which did not reveal, among other things, that this product should not be applied too frequently, or used on an area of the skin larger than the face and neck at any one time, or employed where the skin is broken. The stipulation was supplemental to one signed for the company by C. P. Edwards in April 1941, which remains in effect and provides for discontinuance of claims that the cream affects the skin in a new way or in any way different from that of other preparations.

Palmer's Skin Success Whitening Cream.—E. T. Browne Drug Company, Inc., New York, stipulated in September 1944 to discontinue any advertisements which did not make clear that the cream should not be applied too frequently, or to an area of the skin larger than the face and neck at any one time, or to skin that is broken.

Prunol—In July 1944 the Prunol Company, Atlanta, Ga, stipulated that it would cease representing the laxative action of Prunol as due principally to its prune concentrate and mineral oil element, and that future advertisements would conspicuously warn that Prunol contains phenolphthalein and should not be used when symptoms of appendicitis are present; provided, however, that the statement, "Caution: Use only as directed," would be sufficient if the label instructions contain a similar warning.

Super-Kaps.—Sears, Roebuck & Company, Chicago, stipulated in May 1944 to cease representing that this product will beautify the user or correct nervous conditions except those due to a lack of vitamin B_1 in the diet.

Vitawine and Oculine Products.—In June 1944 the Interstate Laboratories, Louisville, Ky., stipulated to cease representing that Vitawine helps constipation or indigestion, increases energy, cures conditions caused by a deficiency of vitamin B_2, or is prescribed by physicians; or that "Oculine Eye Pads," "Oculine Eye Salve," "Oculine Eye Bath" or "Oculine Eye Drops" is useful in treating eye disorders In 1940 the Food and Drug Administration declared that Vitawine labels falsely represented that product contained blood- and body building ingredients, would remedy anemia and prevent pellagra, diarrhea and certain types of neuritis. They reported it to contain over 14 per cent of alcohol, with citrates of sodium, manganese, iron and ammonium and some vitamin B_1.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1936 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Clinical Significance of Cholesterol. G. L. Muller.—p. 355.
Effect of Bile Salts on Experimental Production of Ulcers in Dog. R. L. Driver and E. B. Carmichael.—p. 378.
*Hyperinsulinism as Factor in Peptic Ulcer. E. M. Abrahamson.—p. 379.

Hyperinsulinism in Peptic Ulcer.—A group of patients with peptic ulcer was subjected to dextrose tolerance tests. The uniformly low late values of blood dextrose fulfilled Abrahamson's prediction that patients with peptic ulcer would have hyperinsulinism. The fact that patients with the clinical diagnosis of peptic ulcer but without x-ray confirmation of peptic ulcer have the same type of dextrose tolerance curves as those in whom the confirmation was present leads to the possibility that the hyperinsulinism, or at least the chronic hypoglycemia, might have some etiologic relationship to ulcer.

Homologous Serum Hepatitis and Infectious Hepatitis.—Neefe and his associates induced homologous serum hepatitis experimentally in 6 human volunteers by the parenteral administration of materials known to contain a causative agent of this disease. After recovery the 6 men were inoculated parenterally with a plasma that contained a causative agent of homologous serum hepatitis in order to test for homologous immunity. Nine normal control subjects without previous history of hepatitis also were inoculated parenterally with the same plasma. None of the 6 men in the test group developed incapacitating symptoms or jaundice, whereas 8 of the 9 controls developed hepatitis with jaundice. The 6 men were then inoculated (1 orally, 5 parenterally) with materials known to contain a causative agent of infectious (epidemic) hepatitis in order to test for cross immunity. Twelve normal controls without previous history of hepatitis also were inoculated with these materials, 6 receiving the infectious material orally and 6 receiving it parenterally. Of the 6 men tested for cross immunity, 5 again developed hepatitis, the evidence being conclusive in 4 and very suggestive in the fifth person. The one without evidence of hepatitis previously had had both infectious hepatitis and homologous serum hepatitis. None of the 6 normal controls inoculated parenterally developed hepatitis, whereas 5 of the 6 normal controls inoculated orally contracted typical infectious hepatitis. The groups employed in these studies are too small to warrant final conclusions regarding the relationship of the causative agents of infectious hepatitis and homologous serum hepatitis. Nevertheless the observations provided considerable evidence that the two agents employed were not identical.

Streptomycin.—This is a report by the Heilmans and their associates of studies which were begun at the Mayo Clinic in September 1944 to explore the possible methods of administration and to obtain some information concerning absorption, diffusion, excretion and toxicity of streptomycin. The antibiotic substance has been administered to human beings in amounts which could theoretically be regarded as therapeutically effective. The number of patients concerned in the study is only partially represented by the 30 tabulated. Streptomycin can be administered intravenously, intramuscularly or subcutaneously, also by the intrathecal route, by nebulization or by the oral route. If intermittent methods of parenteral administration are to be used it should be administered at least every three or four hours in a manner similar to that which has been employed for the administration of penicillin. Diffusion of streptomycin into the cerebrospinal fluid does not readily take place unless large doses are administered. Following parenteral administration, streptomycin is readily absorbed into the general circulation and is excreted for the most part in the urine. Streptomycin is diffused through the placenta and is available in the fetal circulation. It also appears to be concentrated and excreted in the bile. Serious and uncontrollable toxic reactions have not been encountered following administration of fairly large amounts of streptomycin in single or repeated injections. Streptomycin has been administered to some patients for a considerable time without evidence of toxic reactions.

Antagonism of Local Anesthetic Against Sulfonamides.—Walker and Derow investigated certain substances with proved or putative local anesthetic action in regard to their activity as sulfonamide antagonists, confirming and in some cases extending the work of other investigators. They found the inhibitory effect of procaine exactly comparable, mol for mol, with that of para-aminobenzoic acid on sulfathiazole. Ortho-aminobenzoic acid and meta-aminobenzoic acid are without inhibitory effect on sulfathiazole. Three derivatives of meta-aminobenzoic acid (3-amino-4-hydroxymethylbenzoate [orthoform, N. N. R.], 3-amino-4-hydroxypropylbenzoate and 3-amino-4-hydroxybenzoic acid) are likewise without inhibitory effect. The work of previous investigators demonstrating no antisulfonamide action of local anesthetics other than the derivatives of para-aminobenzoic acid is confirmed.

American Journal of Ophthalmology, Cincinnati

Unusual Type of Corneal Opacities. J. W. Henderson and D. R. Gillespie.—p. 1236.
New Permanent Hand Magnet in Light of Present Day Magnet Operation Methods. B. S. Brodsky.—p. 1245.

Penetrating Eye Injuries.—Moncreiff and Scheribel review observations on 183 patients with penetrating eye injuries that were observed at Cook County Hospital in Chicago over a five year period among a total of 691 patients with various types of eye injuries. Of the incised or lacerated wounds, about two thirds of those purely corneal were saved; of the scleral and corneoscleral, less than half. Of the corneal, scleral and corneoscleral ruptures due to contusion, only 40 per cent of the corneal were saved, and less than 20 per cent of the others. Injuries due to a fall or the blow of the bare fist were almost uniformly totally destructive of vision and even of the eye. Broken glass caused 22.7 per cent of all the injuries, and in half of these the eye or the vision was completely lost. There was partial loss of vision in most of the remainder. Nearly three fourths of the 87 eyes on which conservative surgery was done were saved. While the value of the sulfonamides in certain cases cannot be questioned, there were but few cases in which their dramatic effect could be demonstrated Replacement of glass by transparent plastics or unbreakable glass would prevent a large percentage of the serious eye injuries caused by glass. There were 12 patients (over 6 per cent) on whom, through mistaken judgment, conservative surgery was performed instead of prompt enucleation. Consultation with more experienced ophthalmologists might prevent beginners from making mistakes of this kind Sympathetic ophthalmia, as well as other lesser complications, could be prevented if in the absence of any cogent reason to the contrary an eye with a penetrating wound was enucleated within three weeks after injury, *unless the posttraumatic* inflammation had subsided or was well on its way to quiescence.

Control of Typhus in Rural Mexico with DDT.—Ortiz-Mariotte and his associates observed the results of delousing the inhabitants of Mexican villages through application to the clothing of powder containing DDT in 5 per cent concentration and application to the scalp of a lotion of which the basic ingredient is phenyl cellosolve. With 2 exceptions typhus was not present in the communities in which delousing studies were made. In two villages where studies were carried out while epidemics of typhus were occurring, the epidemics subsided rapidly after the application of the DDT powder. The elimination of lice from a village and maintenance of louse free conditions has been found to present more difficulties than temporary delousing to stop the spread of typhus infection. The chief difficulty encountered is that of achieving universal treatment in a community. The effect of phenyl cellosolve lotion on head lice has been found to be only temporary.

Stricture of Male Urethra.—Botsford and his associates present an analysis of 87 cases of urethral strictures treated in an army general hospital overseas; 1,077 cases of urethritis were treated during the same period In 76 of the 87 cases the strictures were a sequel to gonorrhea; 4 were posttraumatic, 1 was congenital and in 6 the history was noncontributory as to cause. Stricture of the urethra is the most insidious and the most common late complication of gonorrhea. Chronic urethral discharge and difficulty in urination were the main presenting symptoms. The urologic investigation of urethral stricture is outlined, with emphasis on the value of cysto-urethroscopy, urethrography and observation of the patient during the act of micturition. Therapy of urethral stricture involves treatment of the stricture itself and of the accompanying infection of the upper, middle and lower urinary tract. Many strictures are readily amenable to instrumental dilation, as is manifested by easy passage of curved sounds to a caliber of 24 or 26 French without bleeding. Dilations are done at six or seven day intervals Urethral dilation was employed in 56 cases. Twenty-six patients had internal urethrotomy. Criteria for the use of this operation are as follows: 1. The stricture is not impermeable. 2. The stricture is located in the anterior urethra, i. e within the penile or bulbous urethra. 3. The stricture is not amenable to dilation, owing either to a tortuous lumen or to associated bleeding from the adjacent urethra distal to the stricture, or inelasticity of the stricture due to dense scar tissue. 4. The stricture is of small caliber, i e. less than 18 French. The operation is done under spinal or caudal anesthesia and the Maisonneuve type of urethrotome is used. External urethrotomy was done on 4 patients. The indication for this operation was the presence of an impermeable stricture causing urinary retention.

Carbon Dioxide and Oxygen with Glycerinized Epinephrine Hydrochloride in Asthma.—According to Lockey, 10 per cent carbon dioxide may be used with 90 per cent oxygen in a pressure tank with the usual reducing valve to regulate the flow. A vaporizer containing 1 100 glycerinized epinephrine hydrochloride is attached to a rubber outflow tube, and vaporization of this material is effected through the attached tube and vaporizer. The patient holds the nozzle of the vaporizer in his oral pharynx and breathes quietly. The author has used this method twenty-eight times Bronchodilator action takes place from the inhaled glycerinized 1:100 epinephrine hydrochloride. Dryness of the tracheobronchial tree is prevented by the use of glycerin, which also helps to raise the humidity of the inhaled air and vapor. The resorbing power of the bronchial mucosa is increased. The sputum is liquefied and the patient is able to expectorate more easily. Long, tenacious, thick mucous plugs are often coughed up after the inhalation of 1:100 glycerinized epinephrine by means of the carbon dioxide and oxygen pressure tank. A small electric mechanical aspirator can be used after inhalation to remove tenacious plugs of mucus.

Acute War Neurosis.—Sargant and Shorvon point out that the phenomena of the "equivalent," "paradoxic" and "ultraparadoxic" phases of the conditioned reflex can be related to acute war neuroses and their treatment. The authors say that from the clinical point of view their most striking observation was the frequency with which they encountered among some patients with acute neurotic states from the battlefields the series of events represented by the sequence: traumatic experience, abnormal psychiatric state exhibiting stereotypy of behavior or thought, artificially induced state of excitement, sudden collapse of the patient into a condition of total cortical inhibition and recovery to a more normal psychiatric state. The last three items of this series are in general parlance covered by the term "abreaction." The authors present 7 case records to illustrate some of the more important observations, especially with respect to experiments on the mechanism of abreaction. One case showed the differing effects of sodium amytal and ether in producing excitation during abreaction and the variable results obtained. Two other cases showed the breaking up of the symptoms of a "stereotypy" when excitation induced under ether is carried on to the stage of ultraboundary inhibition. The relief of focal cortical inhibition, such as loss of voice or stammer, early in ether excitation is demonstrated in 2 other patients. Another case illustrates the combined use of sodium amytal and ether to produce a more controlled and effective type of abreaction in a very excited patient and the symptomatic relief obtained when the ultraparadoxic phase was finally brought about. A seventh case shows that artificially induced excitation under ether will relieve symptoms of hysterical stupor.

Early Diagnosis and Arrest of Otosclerosis.—Fowler says that otologists do not know of a way to diagnose early (subclinical) otosclerosis, a sure way to diagnose early or late ankylosis of the stapedial footplate (clinical otosclerosis), or a cure for the lesion. Otosclerotic foci are found in persons with and without a family history. It is generally held that in the presence of deafness the following signs point to otosclerosis: a pinkish glow from the promontory, an apparent increase of hearing for bone-conducted sound, a positive Gellé test, immovability of the malleus, scantiness of cerumen, hairs and sweat in the external auditory canal, patency of the eustachian tubes, infrequency of colds in the head, a family history of ostosclerosis and no personal prior history of aural disorders. But no one of these is pathognomonic, and even two or three of them are only suggestive of impending otosclerosis, in the absence of deafness. All of them may be absent in the presence of otosclerosis, and all of them may be present in the absence of otosclerosis. Necropsies have shown that 7.55 per cent of white persons harbored otosclerosis, but only about 1 per cent had ankylosis. The author stresses the incidence of inactivity and activity at different periods of life. Ankylosis should be stressed because ankylosis is the cause of the deafness, and it has usually been found accompanied by activity in the lesion. The only impressive sign of beginning ankylosis is a slight lowering of hearing for the lower frequencies. The typical audiometric curve of the patient with uncomplicated active otosclerotic ankylosis shows a loss of hearing which progresses inversely with frequency. Evidence that the fistula operation arrests the lesion is not impressive. It does in some instances and for varying periods improve the hearing considerably, but this can occur irrespective of any change in the activity of the otosclerosis. Every child should be carefully examined otologically when it enters school. A history of progressive deafness in the family should lead the school observer to examine the child more frequently. Interest is centered on endocrine factors and on certain vitamins and minerals. Irrespective of otosclerosis, these are of importance at this time of life.

Microfilarial Granuloma of Spleen: Observations in 12 Additional Cases. R. G. Dhayagude.—p. 275.

Structural Changes in Early Filariasis.—Rifkin and Thompson studied a series of patients from units which had been stationed for thirteen to thirty months in various islands of the South Pacific where filariasis is known to be endemic. They have reviewed a series of lymph nodes and lymphatic vessels from patients suspected of having filariasis on whom biopsies were made at other army medical installations. Their report is based on a detailed study of 30 cases. In the entire series the peripheral blood presented no evidence of microfilarias. Thick and thin smears and Knott concentration methods were utilized. It appears that the adult filaria has the ability to produce a distinct reticuloendothelial response. This response varies with the viability of the parasite. In cases in which a distinct endothelial reaction is induced one must rule out tuberculosis, syphilis and the other chronic granulomas. There appear to be three stages in the genesis of filariasis: the acute stage, manifested by a typical allergic reaction, which may be local or systemic; the subacute or early chronic stage, characterized by the development of a proliferative granulation tissue and occurring in lymphatic tissues harboring the parasites, and late chronic stage of the disease, typified by a nonspecific fibrous tissue overgrowth. Distinct delineation is not possible, one stage merging imperceptibly into the other.

Structure of Liver in Pellagra.—The Gillmans discuss the value of hepatic puncture in estimating the structural modifications in the human liver in pellagra. By an improved liver biopsy technic they removed fragments of liver from 120 patients with pellagra on admission to the hospital. On the basis of the amount, the character and the distribution of fat and pigment and the presence or the absence of cirrhosis, these livers were graded into four main types. In type 1 the characteristic feature is the presence of varying amounts of fat only. This type may be subdivided into six subtypes according to the quantity, the nature and the distribution of the fat. Type 2 contains cytosiderin and cytolipochrome in the hepatic and Kupffer cells only, distributed in the form of discrete granules. Type 3 is very similar to type 2 except that the iron-containing pigment not only is present in the liver cells and the Kupffer cells but is aggregated in large masses in cells lying either in the hepatic lobule or in the portal tracts. Pigmentary cirrhosis of varying intensity is the main feature of type 4. Livers of types 2, 3 and 4 could exhibit the same degrees of fatty change as described in livers of type 1. The type 1 liver is predominantly a feature of pellagrous infants and children, while the pigmented liver, with or without fat, is found in adolescents and adults. Iron pigment arises within the liver cells as the result of a profound disturbance of intracellular metabolism induced by dietary imbalance. The Gillmans stress that the therapy and the assessment of its effectiveness should be based not only on the clinical picture but on the structural alterations in the liver. In pellagrins the fatty change, the formation of intracellular pigment, with or without cirrhosis, and carcinoma represent different patterns of reactivity of the liver cells to acute and chronic malnutrition.

Gelatin Sponge and Thrombin in Hemostasis.—Light and Prentice, who describe surgical investigations on gelatin sponge in animals and in man, conclude that gelatin sponge is an efficient matrix for use in conjunction with thrombin in the "patch technic" of surgical hemostasis. Microscopic studies show that gelatin sponge when implanted on bleeding dura, on uninjured brain or on injured brain provokes a predictable, mild cellular reaction and is absorbed in twenty to forty-five days without residual reaction. The repair of venous sinuses with gelatin sponge leaves the lumen of the vein patent and without evidence of thrombus formation. The use of bovine thrombin in the amounts required for surgical hemostasis in human beings appears to be free from the danger of antigenicity. The "patch technic" of hemostasis is no longer dependent on human blood for its materials.

Penicillin in Chronic Osteomyelitis.—Buchman and Blair made clinical and bacteriologic studies on the results of treatment of chronic osteomyelitis with penicillin with and without surgical intervention on 47 patients presenting a total of 68 lesions. The treatment of chronic osteomyelitis with intramuscular injections and local applications of penicillin without surgical intervention is totally ineffective. If thorough saucerization of the chronic osteomyelitic focus is combined with preoperative and postoperative administration of penicillin and the resulting wound is left to granulate, the penicillin has little beneficial effect. The treatment of chronic osteomyelitis with preoperative and postoperative intramuscular administration of penicillin, thorough saucerization of the focus and primary closure of the resultant wound has given extraordinarily good results in 23 out of 27 cases.

Food Borne Epidemic of Tonsillitis and Pharyngitis.—An epidemic of a food borne streptococcic infection reported by the Commission on Acute Respiratory Diseases occurred at Fort Bragg in November 1943. The epidemic was confined to members of two companies of an airborne infantry regiment. The causative agent was a strain of beta-hemolytic streptococcus of group A, type 5. One hundred patients with type 5 streptococcic infection of the throat were hospitalized from a group consisting of 32 officers and 228 enlisted men. Various types of investigations were carried out. Epidemiologic evidence incriminated creamed eggs as the probable vehicle of infection. The outbreak was explosive in onset, with a median incubation period of thirty-eight hours and a primary attack rate of 42 per cent. Almost all subjects originally infected became clinically ill. The secondary attack rate was 30 per cent, of which half were cases and half carriers. Alternate patients were treated with sulfadiazine. Only a slight decrease in the height and duration of fever resulted from sulfadiazine treatment. While chemotherapy effected striking reductions in total and differential leukocyte counts and in the daily prevalence of beta-hemolytic streptococci in the throat, the changes were transitory and persisted only during treatment. Benefit was not derived from chemotherapy. A significant rise in titer of antistreptolysin or antifibrinolysin was found during convalescence in a high percentage of cases. It is assumed that an antibody response probably occurred in more than 90 per cent of all cases of type 5 streptococcic infection. Similar antibody responses appeared in nearly half of healthy carriers, indicating that a proportion of "healthy" carriers were subclinical cases. Transient carriers did not exhibit an antibody response, while those who carried the organisms for more than ten days did. Subjects with tonsils frequently had confluent exudate, harbored the organisms in large numbers in early cultures and tended to remain chronic carriers. Subjects whose tonsils had been removed had less exudate and fewer streptococci, and they rid themselves of the organisms sooner. Tonsillectomized patients tended to have lower initial levels of antistreptolysin and higher convalescent titers than patients with tonsils. In instances in which sulfadiazine suppressed the growth of streptococci to a considerable degree during the first ten days of illness, an inhibition of antistreptolysin response was demonstrated. Correlation was not found between the severity of illness and either the initial titer of antistreptolysin or the maximum titer during convalescence. The termination or persistence of the convalescent carrier state appeared to be related to the height of the antistreptolysin response.

Untoward Reactions Attributable to Quinacrine.—The report by the Medical Consultants Division of the Surgeon General's Office, based on clinical studies and observations on large groups of patients, emphasizes the following points: 1. The military value of quinacrine in suppressing vivax malaria and curing falciparum malaria far outweighs untoward effects which have been attributed to the use of the drug. 2. Suppressive doses of quinacrine greater than 0.7 Gm. per week should not be employed routinely. This amount has been shown to provide adequate protection against clinical attacks of malaria, provided "quinacrine discipline" is strictly enforced. In clinical treatment of malarial attacks with quinacrine, routine dosage should not exceed 2.8 Gm. in seven days. 3. Quinacrine suppressive medication should be discontinued promptly and quinacrine should not be given for clinical treatment when patients develop atypical lichen planus, unexplained chronic eczematoid dermatoses, unexplained toxic erythematous eruptions, exfoliative dermatitis, severe leukopenia, agranulocytosis and aplastic anemia, acute hepatitis (not including disturbances believed to be due to malaria) or toxic psychoses which can be reasonably attributed to quinacrine after careful clinical study. 4. Drugs other than quinacrine, such as the sulfonamides and arsenicals, may be harmful to patients with the conditions mentioned. 5. Caution should be exercised in attributing disease conditions to quinacrine until complete studies have been made to establish such relationship. Because of the widespread use of quinacrine, its administration inevitably coincides with many diseases with which the drug is not related. Even if a connection is established between quinacrine and a given untoward effect, its significance relative to the military value of quinacrine requires evaluation. Since the use of quinacrine became widespread, clinical attacks of falciparum malaria have been almost eliminated and deaths from malaria have been extremely rare. In general, quinacrine is superior to quinine both for suppression and for clinical treatment.

Diet and Rest in Infectious Hepatitis.—Twenty-six patients with acute primary infectious hepatitis (group A) were treated by strict bed rest and a diet consisting of protein 180 to 200 Gm., carbohydrate 500 to 600 Gm. and fat 50 Gm. per day. Nineteen patients (Group B) were used as controls and were allowed full activity and free choice of food at the ambulatory patients' mess. On the basis of this study Hughes concluded that it is unwise to treat acute infectious hepatitis with jaundice by permitting the patients to be ambulatory during the active phase of the disease and to eat whatever foods they choose. A regimen of bed rest and a high protein, high carbohydrate and low fat diet, as contrasted to a regimen of full activity and regular diet, results in a much greater percentage of patients returned to full duty and a substantial decrease in the period of hospitalization. These conclusions are supported by purely objective data such as the speed of the return of liver size to normal, body weight curves and the speed of return to normal of the icterus index and the blood phosphatase and cephalin cholesterol tests. Further studies will have to determine which of the two factors bed rest or diet is the more important in the treatment of infectious hepatitis.

Penicillin and Heparin in Subacute Bacterial Endocarditis with Cerebral Embolism.—Green reports that, following the detection of Streptococcus viridans in three blood cultures, taken on successive days, of a woman aged 25, who first came under observation because of cerebral embolism, penicillin and heparin were given over ten days until a total of 1,200,000 units of penicillin and 200 cc. of heparin had been administered. One week after completion of the course of treatment the patient was sitting out of bed and six days later was allowed to go home. The treatment seems to have had a favorable influence in recovery from the effects of the embolism.

Penicillin in Hemolytic Streptococcic Throat Infections.—Keith and his co-workers studied cases of acute pharyngitis in the Canadian navy presenting hemolytic streptococci (group A) in throat cultures. The immune response in the blood stream was studied by doing antistreptolysin titers at the onset of the infection and after one month. Since a definite rise in titer is accepted as evidence of a streptococcic infection, the authors had a group of cases in which the diagnosis was certain. Penicillin was administered by the intramuscular route, 20,000 units every four hours, six times daily, until 360,000 units had been injected. This therapy was given to every other patient. The alternate patients were controls and were treated symptomatically. The total number of patients studied was 135; 59 of these were treated with penicillin by intramuscular injection, while 56 were treated symptomatically; 20 were treated with penicillin orally. The average length of time the temperature remained elevated after admission in the penicillin treated group was 3.1 days. In the symptomatically treated control group it was 4.9 days. Of the patients with proved streptococcic infection treated with penicillin 30 per cent continued to harbor hemolytic streptococci at one week and 13 per cent at one month. In the symptomatically treated controls 100 per cent continued to harbor these organisms at one week and 60 per cent at one month. It required six days' therapy to treat adequately the sore throats due to hemolytic streptococci. It also required six days' therapy to rid the throat of the offending organisms and prevent their return in the majority of cases. Penicillin administered orally in adequate quantities by the technic of Little and Lumb was effective therapeutically and also in ridding the throat of hemolytic streptococci.

Symptoms Following Partial Gastric Resection.—The most commonly accepted explanation of the postprandial symptoms known as the dumping syndrome following partial gastric resection is jejunal distention. The inanition which may occur as a result of the postprandial symptoms may be overcome by placing the patient on a high protein diet, starting with a small amount of bulk and gradually increasing the bulk to that amount represented by 2,500 calories. By this method, without increasing the amount of bulk further, a diet with a caloric value of 3,200 calories may be reached which will insure a progressive increase in weight without increasing the severity of the postprandial symptoms. A group of patients who have experienced nausea to a sufficient degree to prevent the eating of several nonconsecutive meals each week has been observed. The nausea was not associated with postprandial symptoms and did not follow the taking of food. A number of patients have been seen who, although they had been symptom free after partial gastric resection, found it impossible to eat enough in the usual three daily meals to regain weight lost after operation. By the dietary method described, a progressive gain in weight was brought about without postprandial discomfort. In some cases hypochromic microcytic anemia developed after partial gastric resection and failed to respond to the usual treatment for hypochromic anemia. The value for hemoglobin improved after a high protein diet with a caloric value of 3,200 calories had produced an increase in weight.

Caffeine Stimulation of Gastric Secretion.—Roth and Ivy demonstrated that caffeine is a potent stimulus of the secretion of acid and pepsin. A synergistic relation exists between caffeine and histamine with regard to the secretion of hydrochloric acid. The authors attempted to determine whether caffeine stimulated the secretion of hydrochloric acid by acting on the central or on the peripheral vagal secretory mechanisms. Tests were made on several groups of cats and on 7 human subjects. The stomach of a cat responded to caffeine by an increased output of acid after bilateral vagotomy or 1 mg. of atropine sulfate subcutaneously. The stomach of man responded to caffeine by an increased output of acid after the administration of 1 mg. of atropine sulfate subcutaneously. The evidence indicates that caffeine stimulates gastric secretion by acting peripherally on some mechanism in the gastric mucosa, probably directly on the parietal cells, since the evidence is not entirely consonant with the view that caffeine causes the release of histamine. The possibility that caffeine may also stimulate gastric secretion in part by acting centrally still exists. The failure of the gastric secretory mechanism of the dog to respond to caffeine is unexplained.

Serologic Reactions in Primary Atypical Pneumonia.—Florman and Weiss made serologic tests on serial specimens of serum from 68 patients with a clinical diagnosis of primary atypical or viroid pneumonia. The tests included the cold agglutinin, indifferent streptococcus agglutinin, elementary body type virus complement fixation and the Kahn flocculation and Kolmer complement fixation tests for syphilis. Almost two thirds of the patients were found to have positive cold agglutinin reactions, nearly half developed positive streptococcus agglutinin reactions, more than a fourth had positive elementary body type virus complement fixation reactions and a sixth had transitory positive Kahn and Kolmer tests. These results were significantly different from those found in 32 control serums. It was demonstrated that a positive streptococcus agglutinin test is more likely to occur in a patient with a positive cold agglutinin reaction, that the majority of persons with positive elementary body type of complement fixation tests do not have positive cold agglutinin tests and that there is no apparent relationship between the occurrence of any of these reactions and transitory positive Kahn and Kolmer tests for syphilis. In a group of 73 consecutively received serums from patients with primary atypical pneumonia only 2 significantly high heterophil titers and 1 Weil-Felix titer were found. The frequency with which the cold agglutinin antibodies and the other previously mentioned antibodies are found to develop in patients convalescing from primary atypical pneumonia suggests an immunologic association with the etiologic agent (or agents) of the disease. The many combinations of response which are measured by the tests reported here may be the reflection of individual variation or of several different agents producing the same syndrome. Until the etiologic agent for the majority of instances of primary atypical or viroid pneumonia is identified, these tests serve the practical purpose of more clearly defining the disease.

Fatal Thrombocytopenic Purpura Due to Sodium Salicylate.—Rappoport and his associates, in reporting an instance of secondary thrombocytopenic purpura caused by sensitization to sodium salicylate fatal to a man aged 35, base the causal relationship on the proved history of sensitization to sodium salicylate, the absence of exposure to any other chemical or infectious agent, the morphologic characteristics of the megakaryocytes, the metaplastic appearance of these elements in the spleen and the failure of splenectomy to improve a thrombocytopenic purpura.

Lumbar Ureterolithotomy.—Prince believes that Foley's lumbar ureterolithotomy should be performed immediately in all cases of calculi in the upper third of the ureter, unless they are of such small size that they give great promise of spontaneous passage within a brief period. This operation is carried out through an incision 7 to 8 cm. in length without the cutting of a muscle; the ureter is never freed from its bed, and there is a minimum of retroperitoneal dissection. The operation is of admirable anatomic design, quick, bloodless and effective.

Excision of Patella.—The report by Young and Regan is based on 21 cases of arthritis of the knee in which excision of the patella was performed at the Mayo Clinic. Fourteen of the patients had osteoarthritis of the knee with moderate or severe involvement of the patella. In 6 cases the arthritis was of the rheumatoid type. In the remaining case, traumatic arthritis had followed recurrent dislocation of the patella. The ages of the patients ranged from 18 to 66 years. Both patellas were excised in 5 of the cases. All of the patients complained of pain in the knee with use. Sixteen of the patients had flexion deformities of the involved knee and only 3 patients had normal motion before operation The remaining 2 patients had complete extension but limited flexion of the involved knee. The excision of the patella was accomplished through either a vertical or a parapatellar incision, and care was taken to suture the reflected portions of the patellar tendon with either chromic catgut or silk sutures after the enucleation of the patella. Postoperative immobilization in extension was maintained for seven to ten days by means of a plaster cast. At the end of this period, physical therapy was started. In some cases motion was regained early, while in others several months were required for the return of motion. In 7 of the 14 cases of osteoarthritis the results were excellent, no pain remaining in the involved knee. The leg can be extended to an angle of at least 170 degrees and flexed to an angle of at least 90 degrees. In the remaining 7 cases of osteoarthritis the results were good in 4, fair in 2 and poor in 1 case. In the cases in which the results were classified as good the pain was relieved but there still was some limitation of motion. In the cases in which the results were classified as fair the pain was relieved almost completely but the range of motion was only a few degrees. In the case in which the results were poor a painful genu varum developed as a result of a destructive process in the medial tuberosity of the tibia. In 4 of 6 cases of rheumatoid arthritis less pain remains than before the operation. Good results were obtained in the 1 case of traumatic arthritis.

Absorption, Excretion and Toxicity of Streptomycin in Man.—Anderson and Jewell studied the absorption and excretion of streptomycin in man. The subjects used for the pharmacologic studies were adult ward patients. Streptomycin was dissolved in distilled water for intravenous, intramuscular and subcutaneous administration in concentrations varying from 50,000 to 150,000 units per cubic centimeter. The solutions used for intrathecal administration varied in concentration from 2,500 to 5,000 units per cubic centimeter. The solutions of the drug were stored at 5 C. until time of use. The authors point out that a unit of streptomycin represents a much smaller amount of antibacterial activity than a unit of penicillin. Thus, when the action of the two substances is studied against Staphylococcus aureus (strain SM), an organism against which both drugs are active, it is found that the growth of this organism is completely inhibited by 0.08 unit of penicillin, whereas the smallest amount of streptomycin that causes complete inhibition is 1 unit. A unit of penicillin represents approximately twelve times as much antibacterial activity for this test organism as does a unit of streptomycin. On the basis of studies on the absorption of streptomycin with various routes of administration, the authors assert that streptomycin is not absorbed after oral administration in amounts sufficient to produce detectable concentrations of the drug in the serum. The failure of the drug to be absorbed from the gastrointestinal tract is not due to the inactivation of streptomycin by the gastric juice. The curves of the serum concentrations of the drug after the intramuscular or intravenous injections do not differ significantly except during the first few minutes after injection. Following the intramuscular or intravenous administration of a single dose of streptomycin, 46 to 87 per cent of the dose injected can be recovered in the urine within twenty-four hours. Streptomycin is excreted more slowly by the kidneys than is penicillin. It appears likely that effective blood levels of streptomycin can be maintained by administering the drug at intervals of six to eight hours. In patients with meningitis, streptomycin diffuses to a slight extent from the blood into the cerebrospinal fluid. The intrathecal administration of streptomycin in doses up to 20,000 units does not produce signs of meningeal irritation. With doses of 10,000 to 20,000 units an appreciable concentration of the drug can be maintained in the cerebrospinal fluid for at least twenty-four hours. No serious toxic reactions follow the injection of single doses of streptomycin in amounts up to 600,000 units or after the continued administration of the drug for periods of two to three weeks in doses totaling 2,725,000 to 18,150,000 units. The intravenous and subcutaneous injection of concentrated solutions of the present preparations of streptomycin causes too much discomfort to warrant the use of these methods of administration. The drug can be administered in an intravenous infusion without the production of unpleasant symptoms. Intramuscular injections are fairly well tolerated for periods up to one to two weeks. Therapy continued beyond these times may cause severe discomfort.

Abnormalities of Parathyroid - Calcium - Phosphorus - Vitamin D Complex.—Hart and Lisa report 9 cases classified as abnormalities of the parathyroid-calcium-phosphorus-vitamin D complex among 91,000 admissions to the City Hospital during the decade of 1935 to 1944. There were 3 patients, 2 women and 1 man, with adenoma of the parathyroid, and 4 patients with bone cysts (1 man, 2 women and 1 boy); 1 case in a man was diagnosed as osteogenesis imperfecta and 1 case in a woman as tetany due to calcium deficiency. There were 7 of the 9 cases in which bone changes were outstanding, 1 case in which kidney changes predominated and 1 in which tetany was the most prominent clinical symptom. Two of the 9 patients had complications. Nephritis and uremia developed in case 2, and there was a history of epilepsy in case 8. There were 3 cases with definite hypercalcemia (those with proved adenoma), 1 with mild hypercalcemia (11.9 mg.), 1 with high normal (11.2 mg.), 1 with both hypocalcemia and hypercalcemia, 1 with normal values, 1 with hypocalcemia and 1 not taken. Except for the second patient, who developed hyperphosphatemia and died in uremic coma, the blood phosphorus stayed within normal bounds. The phosphatase reports were meager. In cases 1 and 2 there was evidence of bone disorder. Removal of a parathyroid adenoma was successful in stabilizing the blood calcium in 3 cases. The first 2 patients developed tetany on about the fifth postoperative day. The therapeutic response to large doses of calcium with parathyroid extract or large doses of vitamin D was satisfactory in all 3 cases. The 4 cases of bone cysts were successfully handled by local surgery. Laboratory studies gave little evidence of a systemic calcium-phosphorus-phosphatase upset, but the pathologic change in the cyst is identical with that found in the generalized form associated with hyperparathyroidism and thereby seems to be a related condition. The eighth case in this series, with a history of epilepsy and with pathologic fractures, bone changes and positive changes in the calcium levels of the blood, points strongly to a parathyroid adenoma; it might have been better diagnosed with present day methods. The ninth case presents a rare type of spontaneous tetany in an elderly person with bone changes but without kidney changes. It could very well have been a lack of vitamin D, as it responded to the usual rickets treatment. The Sulkewitz test for calcium in the urine was employed only once and that time gave evidence of hypercalciuria. Although this test is crude and is influenced by the calcium in the diet, it is useful. No case in this category should go without some estimation of the urine calcium excretion.

Inhibition of Dental Caries by Ingestion of Fluoride-Vitamin Tablets.—Strean and Beaudet report clinical trials with calcium fluoride-vitamin D in children between the ages of 8 and 13. One hundred and seventy-one children were studied in the first series. These were divided into 3 groups of 57 each. The first group received a yellow tablet containing 3 mg. of calcium fluoride, 30 mg. of ascorbic acid and 400 units of vitamin D as calciferol one tablet a day; the second group received one white tablet containing only 3 mg. of calcium fluoride. The third group served as the control and did not receive any tablets. The experiment lasted for six months, and the study was limited to permanent teeth. Sixty children were studied in the second series. Thirty children were given one yellow tablet a day, and the other group of 30 served as controls and did not receive any tablets. This study was continued for eight months. The children in both series lived in an orphanage under similar conditions of diet, and each child had at least three cavities as judged by x-ray. In addition to these two series, tablets were given to a number of dentists who were to distribute them to patients between the ages of 8 and 16. Children between the ages of 8 and 16 not receiving fluorine in their water or food may expect on the average an increase of When cal- 40 to 65 per cent in the incidence of dental caries. cium fluoride was given to the children in the first series the increase in caries was reduced to 27 per cent, and when vita- mins C and D were combined with the tablet the incidence was reduced further to 24 per cent. In the second series, even though this experiment ran two months longer than the first one, the increase dropped to 10 per cent as compared to 24 per cent in the first experiment. It is suggested that this decrease may be explained by the synergistic action of vitamins C and D with fluorine. Fluorapatite may be adsorbed from the surface of tooth enamel and is resistant to bacterial decomposition and lactic acid digestion. Fluorine combined with vitamins C and D in the form of a tablet offers a means of controlling the amount of fluorine to be ingested.

Antianemic Properties of Synthetic Folic Acid.—Spies and his associates studied the effect of numerous substances on reticulocytosis, leukocytic equilibrium and red cell and hemoglobin regeneration. The substances tested included niacin, thiamine, riboflavin, calcium pantothenate, pyridoxine, inositol, para-aminobenzoic acid, choline, pyridoxamine and pyridoxal. They were found to be of little efficacy in treating this type of anemia. Crude folic acid concentrates likewise produced little specific hematologic response. While fractioning reticulogen, Cline isolated several materials of unknown structure which, when given parenterally to patients with macrocytic anemia, produced reticulocytosis. The reticulocytosis which occurs following the administration of a synthetic substance, Lactobacillus casei factor, considered a part of the B complex, is of great interest. The L. casei factor dissolved in isotonic solution of sodium chloride and made alkaline with small amounts of sodium bicarbonate was given intravenously to 5 subjects with macrocytic anemia in relapse. Similar to the subjective sensation that comes on the patient with macrocytic anemia in relapse several days after liver extract, these patients felt a definite upsurge of well being three or four days after the first injection. Persons with macrocytic anemia in relapse have a significant hemopoietic response following the administration of synthetic folic acid. This response follows either parenteral injection or oral administration. In every instance the number of reticulocytes increased in the peripheral blood, and the red blood cell counts and hemoglobin content rose toward normal levels.

Salicylism.—Caravati and Whims present evidence which indicates that the prominent symptoms of salicylism are manifestations of the central effect of the drug; that tinnitus, dizziness, nausea, vomiting, fever, tachypnea and encephalopathies noted when large doses of salicylates were administered are caused by the effect of the drug on the higher centers. Intravenous salicylate therapy is unnecessary. Alkalis should not be given concomitantly with salicylates when it is desirable to reach a high plasma level but should be reserved for use when toxic symptoms develop. Plasma salicylate levels are promptly reduced by alkali therapy.

Erythrocyte Formation.—Sherman studied several patients with pernicious anemia during treatment in which there was a sustained reticulocytosis at a level much higher than can be attained by parenteral liver therapy. To achieve this the hormone addisin (from gastric juice) was used. The total red blood cell count does not materially increase until the reticulocytes disappear. If the reticulocytes were or became red blood cells, the increase should be immediate. Sherman assumes that the nuclear particles, normoblasts and reticulocytes which appear before the red blood cells are agents which stimulate the bone marrow to produce mature red blood cells. He believes that the normoblast, the nuclear particles and the reticulocytes contain in themselves some agent different from the hormone in the gastric juice which stimulates their appearance in the blood stream. This agent is at present unknown but is probably a hormone. When this factor is isolated from the reticulocytes, nuclear particles and normoblasts, it will be capable of causing an immediate regeneration of red blood cells.

Hypochloremic State in Surgical Patients.—Ireneus warns that severe hypochloremia may occur when postoperative patients are on a restricted salt intake. If salt solution is not given in these cases, serious results may ensue. The onset of clinical hypochloremia is insidious. The most important diagnostic lead is obtained by realizing that large amounts of electrolytes and chlorides have been lost without being compensated (for example, bile fistula, vomiting and high intestinal fistula). The clinical picture presents itself as one of shock (blood chlorides below 300 mg. per hundred cubic centimeters). The skin is cold and clammy, and the patient complains of extreme weakness. The pulse and blood pressure are usually unobtainable. The urinary output has acutely decreased to 100 cc. or less for twenty-four hours, with a corresponding rise in the nonprotein nitrogen. The temperature is subnormal. The author presents 4 cases of hypochloremic state occurring in surgical patients. They differ as to the mechanism of the chloride loss. The first case concerned a woman aged 23 with extensive granulating areas following a burn involving 35 per cent of the body surface. Her anemic and hypoproteinemic state was adequately corrected with whole blood and plasma. However, the author failed to appreciate that huge quantities of chlorides and other electrolytes could be lost through the extensive granulating areas until a picture of acute prostration and impending shock presented itself with a blood chloride reading of 327 mg. per hundred cubic centimeters. Ten thousand cc. of parenteral fluids containing 81 Gm. of salt was needed to elevate the blood chloride reading to 445 mg. per hundred cubic centimeters on the following day (normal 450 to 500 mg. per hundred cubic centimeters). The amount of salt given here is considerably more than that which would be given by the Coller "clinical rule" and perhaps was more than was actually needed; nevertheless, the clinical response was immediate and ideal. Hypochloremia in the second case was produced by excessive loss of chlorides through vomiting. The third patient developed hypochloremia because of cholorrhea through a persistent external biliary fistula created when the common bile duct was opened to drain a suppurative cholangitis. A fourth case of painless progressive icterus due to a carcinoma of the common bile duct is similar to the third case except for the absence of a complicating suppurative cholangitis. A high daily maintenance dose of salt was necessary also in this case to compensate for that lost by the bile fistula.

Tetanus.—Gessler analyzed the records of 121 cases of tetanus treated in four hospitals in the twelve years between 1933 and 1944. The average incubation period of those who recovered is 16.44 days, while it was 10.24 days in those who died. It has been long recognized that the incubation period is an important factor in determining prognosis, the short incubation period providing poor prognosis. However, in dealing with an individual case one cannot formulate the prognosis from the incubation period, for many cases that went on to recovery had a shorter incubation period than many cases in which recovery did not occur. The mortality rate was 53.7 per cent. More patients recovered among those who did not have prophylactic first aid than among those who did. More recovered also among those who did not receive prophylactic antitoxin. Thus prophylactic treatment is disappointing. Intravenous or intramuscular injection of tetanus antitoxin is preferable to other routes of injection. An adequate amount of antitoxin would appear to be about 25,000 units for the average case. Intrathecal injection of antitoxin is more hazardous than effective. Local injection of antitoxin about the site of infection seems without value. The older theory of the ability of tetanus toxin to travel up nerve sheaths to reach the central nervous system has given away to the theory of blood stream circulation of the toxin. Hence a liberal surplus of antitoxin injected into the circulation should neutralize the toxin being produced at the site of infection. The patient must have adequate sedation from the beginning of the disease. The use of sodium amytal and/or solution of tribromoethanol is satisfactory in most cases.

Loeffler's Syndrome.—Blanton describes the histories of 4 patients presenting symptoms of Loeffler's syndrome. All gave either a personal or a family history of asthma or hay fever. On the assumption that he was dealing with an allergic reaction of the lungs in the patients with Loeffler's syndrome and that in all probability it was due to localized edema simulating angioneurotic edema, which in turn is believed to be due to hyperpermeability of the capillaries, Blanton used a sympatheticomimetic amine. He injected 0.5 cc. of epinephrine subcutaneously. Roentgenoscopy revealed that this led to the disappearance of the shadows previously seen in the lungs, but later they returned. The author regards this as evidence that his assumption was correct He observed this effect of epinephrine in 3 of his cases

Renal Venous Thrombosis and Infarction in the Newborn.—According to Morison, *hemorrhagic infarction of the kidney is usually considered to be secondary to venous thrombosis.* The author describes 18 cases. *All but 1 of these* occurred in the neonatal period. *In 5 newborn infants thrombi* formed in the intrarenal veins *without producing* infarction of the kidney. In another 5 cases *thrombi* resulted in hemorrhage between the tubules of some renal papillae, in 2 others there was extensive disruption, especially of the medulla, by effused blood, and 2 cases showed both red and pale venous infarcts. These cases are compared with 4 in which there was hemorrhagic infarction without thrombi in the veins, and with 4 in which similar but less severe lesions resulted from pyelonephritis Thrombi were organized or covered by endothelium in 11 cases and had formed first in the small intrarenal branches. Dehydration, continued sepsis and renal venous stasis, but not renal inflammation, appeared to be important in their etiology. Emboli in the small pulmonary arteries and sometimes small areas of infarction occurred in the lungs of 9 of the 14 cases of idiopathic renal venous thrombosis.

Bilateral Adrenal Hypertrophy in Infancy.—A boy aged 6 weeks died of a rapidly fatal disease characterized by severe vomiting with signs suggestive of cardiovascular disturbance—an attack of extreme pallor which ushered in the disease, and respiratory involvement, collapse of the lungs and severe cyanosis At necropsy there were two abnormalities, huge adrenals and a relatively small thymus. There appear to be two classes of children with bilateral adrenal hypertrophy: the first class exhibits features of pseudohermaphroditism, the children often dying with severe, even projectile, vomiting; the second class presents a history similar to that of the child described by Skelton in this paper. They are normal children, more commonly male than female, who in early infancy, usually between 3 and 6 weeks of age, are taken ill with severe vomiting and ultimately die. The underlying nature of the disease is unknown.

Tachycardia in Infancy and Childhood.—Neubauer reports 11 cases of paroxysmal tachycardia observed from 1941 to 1945. Three of the patients were infants of less than 1 year of age; the other 8 were between 3 and 6 years of age. The onset of paroxysmal tachycardia is sudden. The attack lasts for minutes, hours or days. The child appears acutely ill. It is restless at the outset but apathetic once the attack is developed and is pale and often cyanosed There is respiratory distress, with rapid and shallow respirations During the attack, most commonly the heart rate is 160 to 200 a minute, but rates of 270 and 300 have been observed. Between and following attacks premature beats are often found. Signs of congestive heart failure may develop. The heart condition was associated with various infections, diphtheria being most frequent. Distinctive pathologic changes either in the myocardium or in the conductive tissue have not been found in 3 cases in which necropsy was performed. Digitalis given promptly may be effective and save the child's life. Digitalis was not successful in the diphtheria cases of the series. In a case of meningitis, flutter was changed into fibrillation, and this was controlled by digitalis. Quinidine and magnesium sulfate intravenously were also not always satisfactory. Pressure on the carotid sinus or the eyeball, which may stop an attack in an adult, was not effective in infants. This report indicates a rather poor prognosis for paroxysmal tachycardia in infancy and childhood. When a mild infection has been the causative factor, the response to treatment is probably better.

Heart Block in a Diabetic Patient.—Dreyfuss reports that a man aged 58, with complete auriculoventricular block, presented at necropsy only mild arteriosclerotic changes, especially of the coronary circulation. Many series of Adams-Stokes attacks had occurred, accompanied by Cheyne-Stokes respiration. These seizures were caused by ventricular standstill and finally also by ventricular fibrillation. These mechanisms were demonstrated by electrocardiograms; in 1 instance even auricular stoppage was graphically demonstrated. As the anatomic findings do not explain the profound disturbances of cardiac action, and as these attacks usually occurred when diabetic balance was seriously upset, an attempt is made to explain the changes in cardiac behavior by metabolic fluctuations. The appearance of the attacks was controlled largely by the control of diabetes. Only insulin and dextrose respectively were effective in controlling the seizures. Atropine, ephedrine, erythrol tetranitrate and potassium iodide were of no avail. Aminophylline sometimes seemed to shorten attacks when given intravenously and definitely influenced only Cheyne-Stokes respiration. Caffeine occasionally seemed to shorten an attack. Oxygen did not abolish the attacks but had, at least for a few weeks, an interesting effect: during its administration no epileptic convulsions appeared and consciousness was usually not lost completely; the pulse did not entirely disappear, but the periodicity of respiration and cardiac disturbance remained uninfluenced. When oxygen administration ceased, a violent seizure followed almost immediately. The case represents a rare cardiocerebral complication in a diabetic patient the severity of which is illustrated by the violence of the seizures and by the fatal outcome. It belongs in the category of heart disease which might be designated as "nutritional heart disease."

Epidemic Diarrhea and Vomiting.—Brown and his associates report an epidemic of diarrhea in a thousand bed hospital with a nursing staff of 365. Attention was first drawn to the outbreak when 5 babies ranging in age from 3 to 6 days developed diarrhea. Two babies with diarrhea had been admitted previously to a surgical ward with undiagnosed acute abdominal conditions, but any contact with the babies in ward A, which was far distant from the surgical ward, could not be discovered. The cleaner of ward A had had some diarrhea and she would have been in the nursery as part of her normal duties, although without direct contact with the babies. It was soon apparent that this outbreak in no way resembled in severity a previous epidemic of neonatal diarrhea with a high mortality rate which had occurred in the maternity wards at the beginning of the year. Moreover, on that occasion adults had not been involved. Of the total of 111 cases in the present series 20 adults were admitted to the hospital with a history of symptoms, and the remaining 91 cases (including 27 members of the nursing staff and 22 babies) acquired the condition in the hospital. Daily visiting to the patients provided a constant contact with the outside community, and in several instances histories were available of other members of the family suffering from diarrhea and vomiting at about the same time. The possibility of infection brought in from the outside cannot be entirely ruled out, but the fact that 65 of the cases occurred in two neighboring wards points to a degree of local spread within the hospital. Careful inquiry failed to throw suspicion on any foodstuff, milk or water supply as a possible source of infection. Epidemiologic data and previous published work suggest that the infection is due to a virus. The author believes that the outbreak has been widespread over the country.

Acroparesthesia of Hands and Arms in Women.—Walshe observed a number of women, mostly middle aged or elderly, normally unaccustomed to great manual effort, who, under wartime demands, were obliged to take on much heavy work. They developed numbness, tingling and "uselessness" of the hands and fingers, often associated with pain. The response to the treatments commonly adopted was uniformly disappointing, for the patient was expected to follow her normal routine of life. A few of the sufferers discovered that a rest or holiday afforded remarkable relief, suggesting a mechanical origin of the syndrome. There is almost always tenderness of the extensor muscles in the forearm and sometimes of the thenar and adductor muscles of the thumb without muscular wasting. Objective sensory loss is exceptional, although when pain and paresthesias are maximal there may be some blunting of cutaneous sensibility over the digits. Cyanosis or pallor of the fingers is occasional, but Raynaud's syndrome is not an essential part of the picture. The author is convinced that the condition is a manifestation of a rib pressure syndrome. The rib in question is the normal first rib, and traction and compression are exerted on the lower components of the brachial plexus and sometimes also the subclavian artery, when from muscular atonia the muscles supporting the shoulder girdles allow these to droop and remain at an abnormally low level. Acroparesthesia is a mechanically produced syndrome. It is not to be regarded as dependent on abnormalities of metabolism—either toxemic or due to dietary deficiency—or as related to pregnancy. The essential treatment is rest for the limbs.

Thiouracil in Goiter.—In 22 of 33 patients the diagnosis of toxic goiter seemed probable but not certain, and in 11 it was doubtful. The results obtained indicate that thiouracil can neutralize hypersecretion of thyroxine in cases in which the clinical diagnosis of toxic goiter is beyond doubt. Failure occurred only in 2 patients in late pregnancy and in 2 elderly women with fibrillation and heart failure, 1 of them moribund when treatment was begun. The chronic mild toxemia of a large degenerated thyroid gland probably cannot be controlled, as suggested by 2 patients in group 2 who improved after subsequent thyroidectomy. Thiouracil may be employed as a diagnostic agent in deciding to what extent symptoms are due to goiter or to other factors, such as neurosis, although anxiety neurosis may be combined with toxic goiter. If symptoms are nongoitrous in origin, thiouracil has no effect. Hypothyroidism is readily produced in those formerly suffering from hyperthyroidism, but it is extremely difficult or impossible to produce with similar dosage in those with mildly overactive or normally active goiters. Fatality in connection with thiouracil occurs with extreme depression of the leukopoietic system; the case mortality from this is under 1 per cent in the 600 to 700 cases so far reported. The other and milder toxic effects are distressing but transient if the drug is stopped or the dose reduced. The total incidence of toxic reactions in the cases under review by Cookson was 23 per cent.

Irradiation of Cancer of Viscera Exposed at Operation.—Fairchild and Shorter propose combined surgery and direct irradiation for inoperable cancers of the stomach and other viscera. A more accurate and effective dose of radiation at high intensity can be given directly to the tumor and field of local spread, without irradiating a large amount of normal tissue, including vital organs and skin which is unavoidable when irradiating from the skin surface. The authors discuss the surgical approaches for lower esophageal and gastric cancers, also for midabdominal and lower abdominal visceral cancers such as carcinoma of the pancreas or of the descending colon and finally the thoracic approach for upper and midthoracic esophageal cancers. The operative procedures include exploration of the tumor and field of local spread by laparotomy or thoracotomy, also exploration of the whole abdomen or thorax for widespread metastases, which rule out irradiation as a curative measure. In consultation between surgeon, radiotherapist and pathologist it is decided whether the lesion is (1) operable, (2) inoperable but suitable for curative direct irradiation, (3) suitable for palliative direct irradiation only, (4) suitable for palliative operation only or (5) unsuitable for any treatment. When direct irradiation is contemplated, extension of the incision may be necessary. When indicated, operations to relieve obstruction, e. g. gastrojejunostomy and gastrostomy, are done before the irradiation. The tumor is isolated in the open wound and normal viscera are displaced by retraction and packing to minimize the irradiation of normal tissues. Sterilized oiled silk or transparent rubber sheeting protects the field against infection during irradiation. Lead screening is applied to the skin edges when necessary. After the irradiation has been given, the wound is closed. Originally the authors used only one tube to administer a single dose of irradiation directly to the lesion through a parietal opening at the time of operation. This was followed in days by a further dose given through the skin. In later cases the method was modified to give an adequate total dose at one exposure. In the second method two tubes were used. A figure of 1,300 roentgens was decided on as a minimal dose throughout the tumor, entailing a surface dose of 1,350 roentgens from each of the tubes simultaneously. During the past eighteen months 15 cases of visceral cancer have been treated. In 6 of these treatment was purely palliative, because the disease had spread beyond the possible field of irradiation. Little beneficial effect was achieved in this group. From results in the other 9, comprising cancers of the stomach, abdominal esophagus, pancreas and colon, the authors feel that their method will be an advance in the treatment of inoperable cancer of the viscera.

Artificial Dehydration in Rheumatism.—Copeman and Pugh believe that edema and the development of tension as swelling occurs is an important factor in the production of pain and local tenderness in fibrositis. They attempted to reverse this process with a reduction of the fluid content of the affected tissues by inducing dehydration. The distinction between acute and subacute rheumatism and fibrositis is not so precise as is generally held, there being many points of resemblance between them. In view of these facts some cases of acute and of subacute articular rheumatism were also submitted to dehydration. In the first 15 patients fluid intake was restricted for four days to about 8 ounces (225 cc.) daily. Owing to the discomfort caused by so long a period of restriction, it was decided to shorten the treatment to twenty-four hours. During this period neither food nor drink was taken, and fluid output was increased by the administration of sodium sulfate ½ ounce at hourly intervals for 6 doses. The quantity of feces passed was 0.5 to 4.0 liters (average 1.6 liters) and of urine 40 to 560 cc. in the twenty-four hours. As the results obtained by the second method appeared to be less satisfactory, the period of fluid restriction was raised to thirty-six hours, which remained the standard practice for the last 40 cases. Loss of weight was found to vary between 1 and 3.5 Kg. This preliminary dehydration was followed by an intravenous injection of 50 cc. of 30 per cent sodium chloride into one of the veins of the arm. At first the injection was made slowly, but this was followed by intense pain and in some cases thrombophlebitis extending up the arm for several inches. It was later found that, if the injection was made rapidly and leakage round the vein avoided, pain did not arise. Localized thrombosis still developed in about half of the cases but passed off in a few days. Immediately after the injection the patient was allowed to drink 4 ounces of tea to mitigate thirst. Apart from this no fluid was permitted for four hours, after which time further restriction was not imposed, and the patient was encouraged to be up and about. It was believed that if relief of pain should result it would be only temporary. Some patients were apparently cured. In evaluating the effects, a result which fell short of 75 per cent improvement was regarded as not successful. Of 22 patients with fibrositis 13 were graded as successful and 9 as failures. Of 19 with chronic rheumatism 13 were graded as successful and 6 as failures. Pain also disappeared, although usually only temporarily, in more than half of 28 patients with sciatica and evidence of disk prolapse. In this last group relief of pain is probably the effect of shrinkage of nervous tissue and lowering of the cerebrospinal fluid pressure due to the injection of hypertonic solution of sodium chloride.

Goiter in Switzerland.—According to Wegelin, salt with a physiologic dose of iodine was first introduced for general consumption in Switzerland in the years 1922 to 1924. The salt employed contained 5 mg. of potassium iodide per kilogram of salt. At first only a small number of the twenty-two Swiss cantons made the use of this salt obligatory, but gradually other cantons followed. By 1943 there were eight cantons using the iodized salt to the extent of 100 per cent, in eight others it was used by between 50 to 90 per cent and in only six was it used by less than 50 per cent. Since 1936 in the canton of Bern iodized salt has been sold generally except when the purchaser has demanded ordinary salt because of hypersensitivity to iodine. The condition of the thyroid gland at birth is the best index of the efficacy of iodine prophylaxis. Clinicians report a great reduction in congenital goiter. In some cantons it has practically disappeared. Before the period of prophylaxis 1 out of 7 newborn infants in Bern had a large goiter; whereas now the proportion is only 1 in 500. Wespi reports similar results from the maternity hospital in Zurich. He gives pregnant women a salt which contains 20 mg. of potassium iodide per kilogram of salt. He regards 5 mg. as insufficient for pregnant women. At the Institute for Pathologic Anatomy of Bern the incidence of goiters weighing more than 6 Gm. in the newborn decreased from 70 per cent between 1909 and 1914 to 7 per cent between 1940 and 1944. The extremely large goiters, those weighing over 20 Gm., have become extremely rare, only one having been observed since 1935. In Lausanne the percentage of normal glands in persons between 5 and 25 years has increased from 13 per cent before the period of prophylaxis to 60 per cent during the last five years. Partial failure of the prophylaxis may be due to the fact that the iodized salt does not always contain the prescribed content of 5 mg. of potassium iodide per kilogram of salt. The iodized salt prophylaxis reduces the incidence of the severe types of goiter and their fatal sequels, endemic cretinism and most malignant goiters.

Disease of Swineherds a Leptospirosis.—The disease of swineherds is characterized by a diphasic febrile curve. It begins suddenly with a febrile phase of four to six days followed by an afebrile interval of one or two days, which in turn is followed by a renewed increase in temperature of short duration. During this second febrile phase the disease presents the aspects of a serous meningitis. The disease is observed in young people who come in contact with hogs or the excrements of these animals. It prevails in Savoy, the French speaking and the Bern regions of Switzerland, northern Italy and in certain parts of eastern Switzerland. A virus has been assumed as the causal factor, but numerous cases have shown the clinical aspects of a benign leptospirosis. Serologic studies which Gsell carried out during 1944 revealed that swineherds' disease is due to Leptospira pomona. His 39 patients with pomona leptospirosis all had close contact with hogs. Most of them worked on farms where from 60 to 300 hogs were kept. Some were employees of slaughterhouses or masons who had repaired hogsties, and 1 was a truck driver delivering hog feed. In 32 patients who had had the disease recently, the author obtained agglutination titers with Leptospira pomona of over 1:1,000, and in 7 who had had the disease earlier (1 patient eleven years ago) the titer was still around 1:100. The hogs of infected herds do not necessarily present symptoms, and neither did a hog that was inoculated with L. pomona. However, the blood of this animal gave a positive culture and a high agglutination titer. Serologic tests on 173 hogs from different parts of Switzerland revealed in 65 per cent an agglutination titer of 1:100 and up, and in 30 per cent it was over 1:1,000. In 2 apparently healthy hogs the urine contained leptospiras. The author concludes that hogs are the carriers of Leptospira pomona. He says that Clayton of Australia demonstrated L. pomona in young persons with a mild febrile infection who were working in dairies, but Clayton did not suspect a connection with hogs.

Electroencephalography in Craniocerebral Injuries.—According to Puech and his co-workers a patient with a recent injury and with normal electroencephalograms or with a slight deviation from normal will, as a rule, recover rapidly and without surgical intervention provided the alpha rhythm is preserved. A case with an old injury and with abnormal electroencephalographic tracings after coma has subsided presents a serious problem. Deviation from normal may be caused by hematoma, cerebral edema or hypotension. A recent fracture of the cranium, concussion and laceration of the brain may cause slight deviation from normal. The electroencephalographic studies should be made as soon as possible after injury and should be repeated as often as possible, recording simultaneously waves from various cerebral areas. Thus the tracings can aid in ascertaining an improvement in the primary lesion and clarify the situation without resort to operation. In children an injury of the same degree will cause more deviation from normal than in adults. Considerable deviations at the level of the frontal lobes should not be regarded too seriously. Preventive treatment for epilepsy with sedatives is indicated in cases in which definite deviation from normal continues for a prolonged period after injury. Electroencephalograms and the clinical course were followed for one to ten years after craniocerebral trauma in 15 patients. The tracings showed abnormalities in 9 but were normal in the remaining 6. Electroencephalograms can reveal the existence of severe trauma in the past and of a persisting cerebral lesion, but the occasional absence of electroencephalographic abnormality does not exclude the existence of a cerebral lesion.

*Reclus's Disease and Cancer of Breast. F. Fénelon.—p. 1143.
Cancer of Breast and Pregnancy. J. Perrotin.—p. 1147.

Surgical Treatment for Recurrence of Breast Cancer.—Quénu reports 27 cases of local recurrence of cancer of the breast. In 8 of these the primary intervention was limited. In 19 cases primary radical amputation included clearing of the axilla. Nine of these cases presented cutaneous or subcutaneous recurrences; in 1 case there was a recurrence in the axillary lymph nodes, 7 presented a recurrence in the subclavicular lymph nodes and in 2 cases there were "crossed" axillary recurrences. Radical amputation including dissection of the axilla and of both pectoral muscles is indicated in cases in which limited operation was originally performed. Postoperative roentgen irradiation is recommended for local recurrence in which involvement of the axillary lymph nodes was demonstrated on microscopic examination. Surgical treatment is contraindicated in cases of local recurrence with extensive involvement of the skin or of the thoracic wall, particularly in patients with primary radical operation. Definite recovery occurred in only 1 of the author's patients who survived the second operation for ten years. All the others died and the treatment did not considerably delay death or alleviate symptoms during the period of survival. Seven patients were operated on successively for cancer of the breast on both sides. In 5 of these in whom the interval between the two operations was less than four years the longest time of survival was two and a half years. In the 3 other cases, in which the interval ranged from five to eight years, the time of survival varied from six to fifteen years. Radical amputation, including dissection of the axilla, is indicated in secondary cancer, which in the absence of metastases should be treated like a primary local cancer. This applies regardless of the length of the interval between the operations for the primary and the secondary cancer. The prognosis of the second intervention is better in cases with a longer interval.

Reclus's Disease and Cancer of Breast.—Fénelon studied the records of 70 cases of cystic mastitis. Surgical intervention was performed in 52 cases during the period 1925 to 1944. Microscopic examination of 38 of these revealed cancer in 2 patients. In 14 physical reexamination in the absence of microscopic studies or written answers to a questionnaire revealed cancerous growth in 1 patient. Surgical intervention was not performed in 18 cases examined during the period 1925 to 1937. Reexamination or questionnaire revealed malignant growth in 4 cases (5.6 per cent). This percentage exceeds but little the 2 to 4 per cent ascertained by the author for cancer of the normal breast. Malignant growth in Reclus's disease occurs in women of an age in which estrone secretion is reduced. On the other hand, frequent and prolonged administration of large doses of estrone have not caused a pronounced increase in the incidence of cancer of the breast. These facts suggest that the effect of estrone on women may be different from that on mice. One hesitates to affirm that a tumor is benign. Surgical treatment, as a rule, is not indicated in definite cases of Reclus's disease, since the disease is not malignant nor does it predispose to cancer. Clinical examination three times a year or at monthly intervals is recommended in doubtful cases. Surgical intervention may be performed on older patients because of the greater incidence of cancer. Depending on the individual case, surgical treatment consists in total removal of the mammary gland or of mammectomy with the removal of the cutaneous-adipose tissue of the gland. Radical amputation with dissection of the axilla is indicated only in cases in which the diagnosis of cancer is supported by the clinical signs or by the microscopic examination of the removed tissues.

*Panhemocytophthisis During Childhood. F. Oldenberg.—p. 57.
Meningitis Basilaris with Aspects of Chronic Hydrocephalus. I. Gaál and L. Páldy.—p. 104.

Prognosis and Complications of Diabetes During Childhood.—Rosenbusch finds that the long range prognosis of diabetes in childhood, in spite of the great progress in dietetic and insulin therapy, remains less favorable than had been expected. Late complications appear after fifteen or twenty years. The mental status of the diabetic child is usually normal. Rosenbusch was unable to demonstrate intelligence above average. Some diabetic children show psychopathic behavior. The occurrence of a number of organic nervous disturbances with diabetes suggests the possibility of multiple degenerative changes. Height below the average was frequently observed. Tuberculosis and diabetic nephropathy are the most important late complications. The nephropathy of young diabetic patients frequently takes the form of intercapillary glomerular sclerosis as described by Kimmelstiel and Wilson. The author describes cases of this type. Diabetic polyneuritis likewise seems to occur in the young diabetic patient. Eye complications are found fairly frequently in the growing diabetic child during systematic investigations. Examinations with Gullstrand's slit lamp revealed the existence of some opacity after a few years of diabetes in a large number of cases, which may be an early sign of an inadequately balanced metabolism. An early and carefully increasing insulinization seems to be the prerequisite for the prevention of serious disturbances in metabolism and endocrine balance.

Panhemocytophthisis During Childhood. — Oldenberg reports 3 cases of panhemocytophthisis. In 1 case the condition was produced by a micromyeloblastic leukemia, in the second case the cause could not be ascertained, and in the third agranulocytopenia developed following repeated medication with a compound containing phenylethyl hydantoin and phenobarbital. Panhemocytophthisis is a clinical entity with a multiple etiology. A constitutional weakness of the blood forming organs is assumed to exist in the majority of the cases. Association with infectious allergic disorders of the reticuloendothelial system is so pronounced that it seems justified to classify the condition as a disorder of the reticuloendothelial system. Etiologic classification includes intoxication with chemical products, allergic reactions to medicaments, irradiation, infections, blood disorders, particularly leukemias, metastases of malignant tumors, marble bone disease and deficiency diseases. There are cases in which the condition is probably of constitutional origin. The author directs particular attention to the relations between panhemocytophthisis and acute leukemia. The two diseases occur in the same age groups and develop chiefly in males. Panhemocytophthisis may be considered as a preblastomatosis, which under certain conditions may degenerate into a truly malignant leukemic proliferation of the bone marrow.

*Intrabronchial Hyperpressure: Etiology, Diagnosis and Complications: Presence in Bronchopulmonary Cancer. E. S. Mazzei.—p. 1987.

Intrabronchial Hyperpressure.—According to Mazzei a respiratory syndrome due to intra-alveolar hypertension during expiration is frequent in bronchial tumors, bronchial or bronchopulmonary cancer and peribronchial adenopathies of cancer. It may also be caused by foreign bodies in the bronchi, pulmonary tuberculosis and peribronchial tuberculous lymphadenitis, as well as in the course of spontaneous or artificial pneumothorax. Intra-alveolar hypertension suggests obstruction within or about a bronchus, which acts as an intrabronchial valve since it permits entrance of air into the lung with inspiration but prevents total expulsion of air during expiration. As alveolar tension increases, distention of the pulmonary alveoli occurs. Alveolar distention results in aggravation of the respiratory difficulty. It develops in three stages: (1) transient distention of the alveoli during expiration, (2) permanent distention and (3) formation of alveolar blebs. X-ray examination in the first stage shows a clear shadow of a pulmonary lobe, which remains clearer than the shadow of the rest of the lung in expiration. In the second stage the clear shadow occupies either a lobe or an entire lung. The shadow remains unchanged during expiration and inspiration. X-ray examination in the third stage shows permanent emphysematous blebs, pseudocysts and giant emphysema. Early clinical examination, roentgenoscopy and bronchoscopy are indicated. The disease may be controlled if the causal factor is removed early or it may develop into lobular or pulmonary emphysema or giant emphysema in uncontrollable bronchopulmonary tumors and bronchial cancer.

Book Notices

Surgery of the Spinal Column. By Col. Fred H. Albee, M. R. C., U. S. Army, M.D., Sc.D., Earl J. Powers, A.B., M.D., and Lieut. Col. Harold C. McDowell, M.D., M. C., A. U. S. Fabrikoid. Price, $8. Pp. 460, with 229 illustrations. Philadelphia: F. A. Davis Company, 1945.

This work is intended to be a source book on spinal surgery. The authors were motivated by the frequency of spinal injuries incident to civilian life, and the casualties of war. Following a short but interesting chapter on the history of spinal surgery there is a chapter on surgical armamentarium which explains the use of Albee's motor driven instruments and extols the virtues of the Albee-Comper table. Then follow chapters on spinal anatomy, laminectomy, fractures, dislocations, tuberculosis, static deformities, congenital deformities and anomalies, low back disabilities, osteomyelitis, spondylitis, tumors and miscellaneous disorders of the spine. The subjects are covered in a somewhat cursory manner. The section on gunshot and stab wounds of the spine is allotted about thirty-six lines. Albee's recommendation of early spinal fusion in cases of tuberculosis at any age and his advocacy of spine fusions as a primary treatment for fractures of the thoracic and lumbar vertebrae are presented. Dr. Albee's pet thesis that myofascitis is the most important cause of backache is also discussed at length. Albee's methods of bone grafting as applied to various conditions requiring spine fusion are emphasized throughout the book. On page 262 sciatica and locomotor ataxia are listed in the etiology of kyphosis of infancy and early childhood. In general one would not be inclined to consider this work to be a source book on spinal surgery. The coverage of each subject is neither sufficiently broad nor detailed. The subject matter is easily understood, unfortunately at the expense of detailed discussion which one would expect to find in a work of specialized scope. It is a detailed review of Albee's views and methods in spinal surgery. One would not be inclined to recommend this book to the general practitioner. The student of orthopedic surgery might find it too highly specialized. Much of the material is to be found in Albee's older works: Orthopedic and Reconstruction Surgery and Bone Graft Surgery in Disease, Injury and Deformity, Campbell's Text Book of Orthopedic Surgery, Elsberg's Surgical Diseases of the Spinal Cord and the writings of Hodges, Phemister and Brunschwig, Frazier and others. The book has a large assortment of the poorest illustrations that have been submitted to the medical profession in many years. The best illustrations are borrowed.

Psychology of Sex Relations. By Theodor Reik. Cloth. Price, $3. Pp. 243. New York & Toronto: Farrar & Rinehart, Inc., 1945.

This book has as its central thesis the difference between sex and love. The author is a distinguished psychologist who was one of Freud's early students and who has made many important sociopsychologic contributions. "Ritual" and "The Unknown Murderer" are perhaps two of his books which are best known in the United States. His knowledge of Freud and psychoanalysis cannot be questioned. However, his understanding of the developmental history of psychoanalysis in the past forty years seems to be strangely antiquated. He ignores the development of ego psychology, which has occupied psychoanalysts in the past twenty-five years. He terms his revaluation and revision of Freud's theories "neopsychoanalysis." With many of Reik's formulations psychoanalysts would have no quarrel. He seems in the book to be setting up a straw man in order to demolish him. Reik believes that the capacity to love, which shows itself in affectionate tenderness and consideration, does not arise from the sexual urge. Neither is it a sublimation of sexual desire, which he believes is as incapable of sublimation as are pangs of hunger. He presents some interesting speculations on the genesis of love and tenderness. In his overemphasis on his discovery of love, Reik seems somewhat naive. The book is easy to read, except for repetitiousness in the first hundred pages. The general public has often misinterpreted psychoanalysis much as Reik does. The enlightenment which the author has experienced may be helpful to many readers.

Pulmonary Tuberculosis: A Handbook for Students and Practitioners. By R. Y. Keers, M.D., F.R.F.P.S., Senior Physician and Medical Superintendent, Tor-na-Dee Sanatorium, Murtle, Aberdeenshire, and B. G. Rigden, M.R.C.S., L.R.C.P., First Assistant Medical Officer, Tor-na-Dee Sanatorium. With a foreword by F. H. Young, O.B.E., M.D., F.R.C.P., Physician, Brompton Hospital for Consumption and Diseases of the Chest, London. Cloth. Price, $5. Pp. 273, with 124 illustrations. Baltimore: William Wood & Company, 1945.

The authors have grasped the modern trend in teaching tuberculosis in this work, which they describe in the preface as a handbook. The pages are packed with practical instructions. The subject matter is presented in such an interesting manner as to avoid dry repetition and to stimulate interest in diseases of the chest. Here, according to the preface, "the practitioner may obtain an outline of present day therapeutic measures which will enable him to advise and reassure." Emphasis is placed on the fundamental conceptions that pulmonary tuberculosis is a generalized disease which becomes localized in the lungs and that treatment must be directed at the tuberculosis patient, not just the tuberculous lung. The fifteen chapters with numerous illustrations, mostly reproductions of significant x-ray films, follow the usual routine of presentation of this subject—history, bacteriology, pathology, epidemiology, symptomatology, examination, radiology, differential diagnosis, prognosis, treatment, after-care and tuberculosis as a national problem. This concluding chapter is one which might well be read and reread by all persons interested in public health and welfare. It likewise reflects the up to the minute attitude of the authors toward the tuberculosis problem. In several places there are references to practices and conditions which exist in England and do not enter the problem in America. These are of minor importance and do not detract in the least from the value of the volume. This book, covering the disease briefly yet concisely, might well become an outline for teaching tuberculosis today. From it and with it undergraduate and graduate students and practitioners interested in "refresher" studies may readily obtain a practical working knowledge of the modern management of tuberculosis patients both from the physical and from the psychologic (psychosomatic) aspect.

The Medical Use of Sulphonamides. By Various Authors. (Edited by F. Hawking and F. H. K. Green.) Medical Research Council War Memorandum No. 10. Second edition. Paper. Price, 1s. 3d. Pp. 71. London: His Majesty's Stationery Office, 1945.

As the authors state in the introduction, it was thought desirable to prepare a concise review of the clinical indications for some of the principal sulfonamide drugs in the light of their current or potential availability in Great Britain. Since the appearance of the first edition in 1943 rapid advancements have been made in this field of therapy, and a concise and authoritative revision, such as the present revision reflects, is highly desirable. This compact work reviews the chemistry, pharmacology and general principles of sulfonamide therapy. In addition there is a discussion of the relationship of sulfonamide therapy to penicillin. Treatment of various infectious diseases are detailed, and the limitations of this type of therapy are stressed. Pertinent references to the extensive literature on the subject are interspersed throughout the text. Although American clinicians will not be in complete agreement with some of the statements, particularly with reference to the topical use of the sulfonamides and their prophylactic and therapeutic applications in burns and wounds, this memorandum represents an excellent presentation of the subject. It should be of considerable aid to practitioners who in the busy years of war have not been able to keep up with newer developments.

Willis Rodney Whitney: Pioneer of Industrial Research. By John T. Broderick. With foreword by Dr. Karl T. Compton. Cloth. Price, $3. Pp. 324, with 7 illustrations. Albany, N. Y.: Fort Orange Press, Inc., 1945.

Those who are interested in research will enjoy this biography. Others who are interested in people and their lives will also enjoy the book, as it reveals the life of a man responsible for many advances in the electrical field. It is well written, interesting and provocative; no one with a curious mind can read such a book without wondering about research, past accomplishments, future possibilities and the supply of such men as Willis R. Whitney, who, as director of the Research Laboratory of the

General Electric Company, tore apart veil after veil of secrecy in electricity and came forth with scientific facts for the betterment of mankind. One can now better understand why Floyd Gibbons had so much reason to call this laboratory the House of Magic; the man primarily responsible for the activities in the laboratory had an innate and unsatisfiable curiosity and was never happy unless he was doing something to feed this curiosity. He, as they say, did things, and the reasons are well revealed in his biography and should be a source of encouragement to other would-be scientists who in moments of stress wonder if the struggle is worth while. It is, and the life of Whitney serves as a good example.

Adult Adjustment of Foster Children of Alcoholic and Psychotic Parentage and the Influence of the Foster Home. By Anne Roe, Ph.D., and Barbara Burks, Ph.D., with a chapter on Sibling Adjustment in collaboration with Bela Mittelmann, M.D. Memoirs of the Section on Alcohol Studies, Yale University, No. 3. Paper. Price, $2. Pp. 164. New Haven: Quarterly Journal of Studies on Alcohol, 1945.

This excellent study touches on a matter of primary importance in medical psychology: "The problem of the relative influence of heredity and environment on the course and outcome of human lives." It is, in essence, a sociopsychologic, statistical survey which has a bearing on matters often—and without foundation—regarded as foreign to medical science. The adjustment of the child who has been handicapped not by tangible, immediately observable and frequently organic limitations but of the one who is impeded by the imponderable and abstract features of living is an extremely significant avenue for research. When it is considered that the authors of this study had to channel new avenues toward their goal and to work with specially fashioned and self-admittedly inadequate tools, one is pleased and surprised with the results as regards both the matters at hand and the directions implied. The single criticism applies to the bibliography, which is lacking in background material for work of this kind and constitutes an impediment to the project if it betrays or gives clues to the orientation of the authors. At the same time, however, this kind of study is regarded as pioneering, and it deserves a better hearing than it probably will get.

Materia Medica, Therapeutics and Pharmacy: Description of Drugs, Therapeutics, Practical Pharmacy, Metrology, Pharmaceutical Arithmetic, Prescription Writing in Apothecary and Metric System, Narcotic Drugs, Sulfa Group of Drugs, Penicillin, Special Therapeutics, Older Drugs, Tables for Reference, Urinalysis, Technic of Urinalysis, Poisons and Antidotes, Dosage Rules, etc., as a Text Book for Students in Colleges of Chiropody and as a Reference Book for the Chiropodist. By Howard T. Kearney, Ph.G., R.Ph., D.S.C., Professor of Materia Medica, Therapeutics and Pharmacy, Illinois College of Chiropody and Foot Surgery, Chicago. Cloth. Price, $6. Pp. 494. Chicago: Chiropody Record Publishing Company, 1945.

This volume, which is intended only for students and practitioners in the field of chiropody, is divided into four principal parts devoted to materia medica, therapeutics, pharmacy and prescription writing. Included in these sections are chapters and discussions on the history, classification, preparation, administration, uses and actions of drugs, incompatibilities, equivalent measures and weights, toxicology, narcotics, insulin, blood plasma, vitamins, general and local anesthesia, kidney functions, urinalysis and other laboratory tests. There is also an alphabetical list of drugs and illustrative material on prescription writing. It is readily apparent that much of the material in this book is outside the scope of chiropodial practice and can be of little practical value to students in this field. Other parts may serve as reference, but the book as a whole is not of textbook caliber in its present form.

Fires in Hospitals and Institutions. Paper. Price, 50 cents. Pp. 48, with illustrations. Boston: National Fire Protection Association, 1945.

Although a fire under any circumstances is likely to be costly and disastrous, a fire in a hospital or a home for the aged, the infirm or the orphaned has added hazards and menacing aspects which make it even more catastrophic. In this pamphlet are collected the records of a number of such fires, among the worst the tragedy of the burning of the Crile Clinic in 1929 and of the Evansville State Hospital for the Insane in 1943. There are several pages of records of other fires in hospitals, convalescent homes and homes for the aged which indicate their seriousness. Most of the fires began in service rooms of the buildings, indeed more than half of them in closets, laundries, elevator shafts, boiler rooms, work shops or linen rooms. Most of the losses could have been avoided with proper use of automatic sprinklers and adequate attention to making the building safe against fire. Two pages on planning for fire safety contain invaluable lessons for every superintendent of a hospital or medical institution.

The Great Stewardship: A Story of Life Insurance. By Albert W. Atwood. Cloth. Price, $2.50. Pp. 201. New York & London: Harper & Brothers, 1945.

In the decade that started in 1843 fifteen life insurance companies were founded which are still leaders in their field. Today there are 70,000,000 policyholders in the United States, and the insurance in force amounts to 148 billions of dollars. This book tells the story of the origin and growth of life insurance. A special chapter on health and longevity is of particular interest to the physician. The author is convinced that private management and competition have been largely responsible for the magnificent growth of the life insurance system, but he recognizes also the part played by government regulations and supervision. The final chapter is entitled "Social Insurance Plus Life Insurance." Mr. Atwood feels "there should be no conflict between social security and life insurance, or any other types of security that come from the exercise of personal industry and thrift, unless the benefits offered by social security are so large and attractive in themselves that many people will not make additional provision." He says that "the 'will to work' will be weakened and destroyed if social security benefits become confused with what men can do for themselves."

Conditioning Exercises for Girls and Women. By Anne Schley Duggan, Director the Department of Health, Physical Education and Recreation at the Texas State College for Women, Denton, Texas, Mary Ella Montague and Abbie Rutledge. Cloth. Price, $2.50. Pp. 116, with illustrations and music. New York: A. S. Barnes and Company, 1945.

This book serves as a convenient guide to the woman teacher of physical education who wishes to use systematic exercise as a method for improving the physical condition of girls and women. The objectives of conditioning exercises and their place in the total program of physical education for women are discussed. The suggested exercises are carefully analyzed in terms of kinesiology, physiology and effects specific to each part of the body. The clear and precise directions for teaching each exercise will be of help to the beginning or inexperienced teacher. The chief value of the book, however, lies in the fact that it has been written for women with direct reference to their needs and abilities. The methods described depart from the rigid technics of the older systems of formal exercise, which were designed primarily for men and boys, and by an adaptation of many technics of the modern dance a series of exercises are devised which, though strenuous, are primarily feminine in character. Excellent illustrations accompany the text, and scores for the musical accompaniment are provided in an appendix.

Vitamins and Hormones: Advances in Research and Applications. Edited by Robert S. Harris, Associate Professor of Nutritional Biochemistry, Massachusetts Institute of Technology, Cambridge, Mass., and Kenneth V. Thimann, Associate Professor of Plant Physiology, Harvard University, Cambridge, Mass. Volume III. Cloth. Price, $6.50. Pp. 420, with illustrations. New York: Academic Press, Inc., 1945.

The third volume of this series on vitamins and hormones includes contributions from fourteen individuals in England, the United States and Palestine. These research workers report on the interrelation of vitamins, the synthesis of B vitamins by intestinal bacteria, sulfonamides and vitamin deficiencies, manifestations of antepartum nutritional deficiency, growth factors in microbiology, synthetic estrogens, chemistry of anti-pernicious anemia substances of liver, action and metabolism of gonadotropic hormones and the role of acetylcholine in the mechanism of nerve activity. Those who want a monograph on advances in research and applications of vitamins and hormones will find this volume a useful reference source. Of course the advanced worker will obtain greatest value, but any one interested in hormones and vitamins would read this book with profit. It is the type of monograph for which there is much need and of which there should be more in other fields.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

HEIGHT AND WEIGHT AS AFFECTED BY GENERATION AND AGE OF MOTHER

To the Editor:—Are children born of women in older ages as strong or as tall as children born in youth? Is the stature of our people growing taller or shorter, or does it stay about the same?

C. Raimer Smith, M.D., Decatur, Ill.

ANSWER.—The first part of the question is difficult to answer, for not much information is available. Waaler, basing his studies on Norwegian children, states that there is no biogenetic reason for child growth to suffer when correlated with the parity of the child and the age of the mother. If there is any growth deterioration it is socioeconomic, owing to the fact that in the lower income groups later children often add to the financial burden to the point where their health and dietetic care suffer.

We are growing taller and heavier. It has been said that in the last four generations the gain has been 1 inch (2.5 cm.) and 5 to 7 pounds (2.3 to 3.2 Kg.) per generation. Here are some figures for the United States:

	Height	Weight
Harvard fathers	173.95 cm.	140.24 pounds
Harvard sons	177.50 cm.	150.30 pounds
American college youths, 1916-1917	67.15 inches	132.05 pounds
American college youths, 1935-1936	69.23 inches	141.79 pounds
American college girls, 1916-1917	62.93 inches	119.00 pounds
American college girls, 1935-1936	63.72 inches	120.88 pounds

These figures show consistent gains in height and weight, save in female weight. Here the lack of gain probably is due to "dieting."

MULTIPLE SCLEROSIS

To the Editor:—What is there new in the treatment of multiple sclerosis?

Morris B. Schwartzfarb, M.D., Bronx, New York.

ANSWER.—Based on Putnam's venous occlusion theory, at least in regard to the assumption that a faulty blood clotting mechanism precipitates venous occlusion in multiple sclerosis, the prothrombin and coagulation times have been estimated in 28 untreated cases (Reese, H. H.: Multiple Sclerosis and Dicumarol Therapy, *Tr. Am. Neurol. A.* **70**:78, 1944). The coagulation time was normal, but an apparent hypoprothrombinemia was found in most of the cases. The use of the anticoagulant dicumarol for three to five days weekly in dosages of 1.5 to 3 mg. per kilogram was without any observable benefits. The results seemed to contradict Putnam's venous occlusion theory. A similar result has also been reported (Moore, M. T.: *Tr. Am. Neurol. A.* **70**:81, 1944).

The use of another anticoagulant, heparin, which prolongs coagulation time by neutralizing the circulating prothrombin and also inhibits platelet agglutination, requires frequent or continuous intravenous administration and is therefore expensive. No claim of cure can be made for it. The use of desensitizing allergens is also under clinical investigation. The effect of a warm climate is said to be favorable (Freeman, Walter: *M. Ann. District of Columbia* **13**:1 [Jan.] 1944; **13**:58 [Feb.] 1944). Fever therapy, either by typhoid vaccine intravenously or by malaria, has not yielded good results and the use of liver extracts and large doses of thiamine have not prevented relapses. There may be some indication, however, that vitamin therapy may reduce the severity of a relapse, but at the present time no conclusive statement is justified. Quinine has also been used extensively in the treatment of multiple sclerosis, but its value remains unproved. "Deleading" patients and the removal of other "toxic" metals has proved futile.

Freeman and most other neurologists agree that prolonged rest is the best form of treatment for the acute stage of multiple sclerosis, and a warm climate and freedom from upper respiratory infections may be the best insurance against a recrudescence. As no specific remedy is known, the patient must depend on his own immunity mechanisms to hold the disease in check. The building up of this resistance by rest and freedom from other illness is the only fully recognized form of treatment of multiple sclerosis at the present time.

Another drug used in the treatment of multiple sclerosis is histamine, a powerful dilator of capillaries. Histamine diphosphate in a 1:250,000 dilution is given by the drip method. The reports are somewhat encouraging, and in some instances prompt improvement has been noted (Horton, B. T.; Wagener, H. P.; Aita, J. A., and Woltman, H. W.: Treatment of Multiple Sclerosis by the Intravenous Administration of Histamine, THE JOURNAL, March 18, 1944, p. 800). The procedure appears safe, as pulse and blood pressure are not affected by repeated injections (Benson, A. J., and Horton, B. T.: *Proc. Staff Meet., Mayo Clin.* **20**:113 [April 18] 1945).

No form of treatment can be expected to grow axons back again after they have been destroyed. The lesions of multiple sclerosis go through an acute stage and then become chronic. Practically all the damage is done during the acute stage. The aim of treatment should be to preserve the patient from subsequent relapses. Almost all patients show spontaneous improvement and, if given at the appropriate time, any form of treatment may encourage a patient temporarily. Investigators in general are extremely skeptical of reported improvement from any form of treatment. The aim of treatment should be to prevent relapses, not in an expectation that myelin will be regenerated or a glial scar dissolved (Putnam, T. J.: *Tr. Am. Neurol. A.* **70**:82, 1944).

DRUGS AND PSYCHOLOGY AS COERCIVE DEVICES

To the Editor:—Is there any definite proof of the use of drugs or of psychologic methods to make jailed persons sign statements detrimental to them?

M.D., Colorado.

[This question has been referred to two qualified consultants, whose respective replies follow.—EDITOR.]

ANSWER.—There is no definite evidence that drugs have been used to force individuals to self-destructive acts or statements. The experience with so-called truth serums (which include scopolamine and intravenous barbiturates such as amytal and pentothal) is that the subject tells of true experiences or of fantasies which he has had. Even under hypnosis it is impossible to make a person perform acts which are not condoned by his own conscience. However, it is quite likely that drugs, with or without hypnosis, would be effective in causing a man to sign his name to a statement.

Proof is lacking that the use of any drug or any other method is used to make persons in police custody sign incriminating statements. In this country certain drugs such as scopolamine and sodium amytal have been used for interrogation purposes, but the effects of these drugs are such that it is not believed a signature could be obtained from the subject which would in any way resemble his ordinary style of writing. The possibility raised by the question must be discounted if for no other reason than the practical one that suspected persons could be coerced without the use of any drug into signing statements in their normal handwriting. In other words, any agency desirous of obtaining a signed statement from an unwilling subject would not find it worth the trouble and effort to use drugs for that purpose. However, certain drugs have been used by investigators for interrogation purposes. Abuse of such methods, that is, the use of the drug on an innocent person for the purpose of obtaining an incriminating statement, is rare if existent at all.

CHLOASMA

To the Editor:—A patient has chloasma. I should like to know whether anything new has been discovered to overcome or control the pigmentation of the skin.

F. G. Krum, M.D., Hamburg, Pa.

ANSWER.—The pigmentation occurring in chloasma is somehow related to the ovary, or perhaps it should be stated that it is not uncommon during pregnancy. In addition, some relationship to vitamin C was described by Cornbleet a few years ago. Not all cases have responded to large doses of vitamin C, but it is worth trying out. Ovarian preparations, either natural or synthetic, have not been particularly satisfactory. Neither is external therapy satisfactory.

VITAMIN K FOR ALLERGY

To the Editor:—Have you any information regarding the use of vitamin K in urticaria?

M.D., New York.

ANSWER.—Recently J. H. Black has reported (*J. Allergy* **16**:83 [March] 1945) gratifying results with the use of 6 mg. of vitamin K daily in the treatment of chronic urticaria and angioneurotic edema. Of these who failed to obtain relief by the usual methods, 62 per cent were relieved by vitamin K therapy. The duration of treatment varied from one to four weeks. Other workers have failed to obtain results comparable to those of Dr. Black.

REACTIONS FOR SYPHILIS FOLLOWING MALARIA AND DENGUE

To the Editor:—Many veterans are being examined who have positive serologic tests for syphilis but no history or physical evidence of the disease. A large percentage of these men have had recurring malarial paroxysms. Occasionally recent infections such as dengue fever or chancroid or a recent vaccination against typhoid are reported. What are the most reliable procedures for diagnosis in such cases? What relation does reagin titer bear to true and false positivity? What percentage of patients with asymptomatic chronic malaria have false positive serologic reactions for syphilis? In patients with chronic malaria not having paroxysms, how often are the malarial parasites demonstrable by the thick smear method? Is it advisable to employ routinely the heterophile agglutination test for infectious mononucleosis in these cases? Is there any record of patients with dengue fever yielding false positive reactions for syphilis? Does typhoid vaccination ever yield similar reactions? If so, for how long and what percentage?

Arthur A. Rodriquez, M.D., South Charleston, W. Va.

Answer.—The problem raised is one of major importance. At separation centers somewhere between 1.5 and 3 per cent of separatees are discovered to have positive blood serologic reactions for syphilis previously unrecorded. As suggested in the inquiry, a considerable number of those with positive serologic reactions have had malaria, recent vaccinia or other conditions which are known causes of biologic false positive serologic tests. It is highly desirable that the diagnosis of syphilis be not made in such instances on the basis of a single unsupported positive blood reaction but that the patient be carefully studied to rule out the possibility of false positivity. The differentiation of true from false positive serologic reactions is often a matter of extreme difficulty involving a complicated investigation of the patient and sometimes of his familial and sexual contacts. A suggested method of procedure is outlined in a paper by Moore, Eagle and Mohr, in the article Biologic False Positive Serologic Tests for Syphilis: III. A Suggested Method of Approach to Their Clinical Study (The Journal, Nov. 9, 1940, p. 1602). Of the several procedures suggested in this paper, one, the Kahn "verification" test, has now been demonstrated to be worthless, as are all other so far described "verification" tests.

To reply so far as possible to the other specific questions: By and large the reagin titer on the basis of quantitatively performed serologic tests is low in patients with false positive tests and high, or at least relatively higher, in patients with syphilis. There are, however, many exceptions to this statement, since an occasional patient with a biologic false positive reaction is found to have a high titer and many patients with long-standing syphilitic infection, whether or not previously treated, are found to have low titered tests. The major point of importance in differentiation between false and true positive tests is not the titer on a single occasion but instead the quantitative results on serially tested specimens, taken at intervals of several weeks and over a period of from three to six months. In the majority of patients with biologic false positive reactions the titer tends to fall or the test to become completely negative, whereas in syphilis the titer tends to remain fixed or, in the case of recent infections, to rise. There is no information as to the percentage of persons with chronic asymptomatic malaria who give false positive serologic tests for syphilis. Available information indicates that in most patients with acute episodes of malaria the blood serologic test may become positive during the febrile period only, the positive test disappearing within a few days or weeks thereafter. In chronic asymptomatic malaria the percentage success of demonstration of malaria parasites by the thick smear method depends entirely on the expertness of the examiner and may range from 0 to 50 per cent.

Since infectious mononucleosis is a frequent cause of biologic false positivity in serologic tests, and, since the disease in mild form is certainly widely prevalent, it is desirable to employ a heterophile agglutination test routinely for all patients suspected of biologic false positivity.

The question of false positive serologic reactions for syphilis in dengue fever has been referred to Lieut. Col. Charles R. Rein, M. C., Army Medical Center. He says "We have received about a dozen specimens from presumably nonsyphilitic individuals with a history of a recent episode of dengue. These specimens gave positive serologic reactions for syphilis. We were unable to follow the patients for a sufficient period of time, but some of them did revert to seronegativity in a short period. It was impossible to exclude malaria, infectious mononucleosis and other nonsyphilitic febrile diseases in these patients, so that I am not certain whether the positive serologic reactions were due to dengue or to something else."

It is believed that typhoid vaccine does not cause false positive serologic tests.

The most recent extensive review of the subject is Biologic False Positive Reactions to the Tests for Syphilis by Herman Beerman (*Am. J. M. Sc.* **209**:525 [April], **210**:524 [Oct.] 1945).

CODEINE IN HEAD INJURIES

To the Editor:—What are the contraindications to the use of codeine for the relief of pain in head injuries? Forrest C. Leiter, M.D., Chicago.

Answer.—The dangers from the use of codeine for the relief of pain with head injuries are relatively slight. Codeine, like morphine, is a central respiratory depressant, although to a considerably lesser degree. For that reason it should be used only for the relief of pain and not to reduce restlessness, which in fact it may aggravate. It should not be given to stuporous or semistuporous patients. It should not be administered in unusually large amounts or with unusual frequency. However, the combination of codeine to relieve pain and paraldehyde for extreme restlessness proves both safe and useful in many cases. Care must be taken not to confuse the increasing stupor produced by intracranial pathologic conditions with the sleep induced by such medication.

HEMANGIOMA OF SPINE

To the Editor:—I have a patient who has for four months suffered with what we used to call sciatica. Pain starts in the left hip and follows the nerve down the thigh to the calf of the leg. The condition was diagnosed by a competent man as hemangioma of the fourth lumbar vertebra. He recommended high voltage x-ray therapy, of which eight treatments have been given. The patient is improving gradually and has pain only from too much walking or standing. Pain stops immediately from sitting. What is the prognosis as to cure and liability to recurrence? May it become malignant? C. J. Lidikay, M.D., Kansas City, Kansas.

Answer.—If we take the diagnosis of hemangioma of the fourth lumbar vertebra to be correct, the chances are good that this patient will definitely receive relief from high voltage x-ray therapy. If his trouble continues and paraplegia should develop, a laminectomy would be necessary to decompress, as it were, the spinal canal, thus giving more room for the cord and the blood vessels. These hemangiomas are not truly malignant and it is rare indeed that they develop into a true malignant tumor.

ULTRAVIOLET LIGHT FOR AIR DISINFECTION

To the Editor:—I am taking care of a family of five in which there is almost uninterrupted infection of the upper respiratory tract, making the rounds with the start of the cold weather. Is an apparatus for treating the air with ultraviolet light of any real value in helping to cut down cross infections? If not, is there anything else on the market in the form of real value in helping to cut down cross infections? And, if not, is there anything else on the market in the form of a spray or some mechanical appliance that would be of any benefit in a case like this?

M.D., Massachusetts.

Answer.—Assurance cannot be given that any ultraviolet device or any spraying device, employing for example aerosols, will fully prevent recurrences of infections such as mentioned in the query. It is true that there are bacteria in the air and that ultraviolet rays of proper length and aerosol sprays, and perhaps other sprays properly used, may reduce the bacterial content of occupied spaces.

ELECTROCAUTERIZATION OF CERVIX AND CANCER

To the Editor:—Since deep burns are conducive to skin cancer, does it not follow that cervical electrocauterization, commonly practiced in the doctor's office, may be contributory to squamous cell cancer of the cervix?

S. L. Governale, M.D., Chicago.

Answer.—So far as is known, there is no evidence in the literature to indicate that electrocauterization of the cervix is a contributing factor in the causation of cancer of the cervix. On the contrary, it is generally believed that this measure is an effective prophylactic against cervical cancer.

WATERY CYSTS OF THE CONJUNCTIVA

To the Editor:—My previous letter on watery cysts of the conjunctiva appeared in The Journal Aug. 25, 1945, page 1260, and a comment in the October 13 issue, page 532. I have recently found a description of what I had in mind in Weeks, J. E.: Diseases of the Eye (Philadelphia, Lea & Febiger, 1910, p. 258): "This consists in dilatation of some of the lymph channels, usually of the ocular conjunctiva. It appears in small, slightly elevated, transparent vesicles, usually associated in chains, very superficially situated in the outer or inner half of the bulbar conjunctiva. The vesicles are irregular in shape and vary much in size, seldom exceeding a diameter of 3 millimeters. The vesicles may be readily moved over the underlying tissue. They sometimes produce irritation and are accompanied by congestion of the conjunctiva in which they lie but are not, as a rule, a source of pain. The vesicles are due to interference with the lymph stream by obstruction. Elderly individuals are more frequently affected than young individuals. Treatment: The vesicles may be excised, or they may be very satisfactorily destroyed by means of the fine galvanocautery point." F. P. Thompson, M.D., Chicago.

THE SURGICAL TREATMENT OF ARTERIAL HYPERTENSION

MAX M. PEET, M.D.
Ann Arbor, Mich.
and
EMIL M. ISBERG, M.D.
Miami Beach, Fla.

Since the first bilateral supradiaphragmatic splanchnicectomy and lower dorsal sympathetic ganglionectomy was performed by one of us (M. M. P.) in November 1933, more than 1,500 patients have received this surgical treatment for essential hypertension at the University Hospital as of September 1945. Surgical treatment has long been accepted here as an integral part of the therapeutic armamentarium for hypertensive disease. Its acceptance has been tempered with the realization that its limitations are definite, that its failures are not uncommon. Rarely does surgical treatment result in a cure of hypertensive disease, but it has given remarkable benefit and prolonged the life of many hypertensive patients.

Reports of the results of surgical treatment in hypertensive disease are numerous. For the most part they are concerned with small groups followed postoperatively for a relatively short time. The largest series of cases previously reported is that of Peet, Woods and Braden,[1] with results in 350 cases followed for nine months to seven years. The most recent evaluation of a significant series is Smithwick's[2] 156 patients followed one to five years.

Those familiar with the life course of hypertensive disease readily realize that much time must be allowed to elapse before passing judgment concerning the influence of a therapeutic incident on the life history of a chronic, constitutional disease. It is with this thought in mind that we present the results in 437 cases of essential hypertension treated surgically five to twelve years ago.

CLASSIFICATION OF HYPERTENSIVE PATIENTS

Essential hypertension is a disease complex with great individual variations. In evaluating the effect of surgical treatment on this variable constitutional disease it is advisable to classify patients according to definite categories in order to determine the *influence of the* operation on the individual category. In this way the knowledge gained may enable intelligent selection of candidates for surgical treatment. In this way one may learn what to expect from the operation for each clinical type of essential hypertension.

A classification based merely on the height of the blood pressure level or on the width of the pulse pressure fails to take into consideration the constitutional effects of the disease. The degree of elevation of blood pressure is not a sound prognostic criterion. In their study on a large group of persons with transient hypertension, Levy, White, Stroud and Hillman[3] found no significant differences apparent between the various systolic and diastolic levels in relation to the death rates with cardiovascular-renal disease. The relative height of a temporary rise in blood pressure did not appear to foretell the severity or extent of the lesions which eventually were the cause of death.

The classification of Keith, Wagener and Barker,[4] based primarily on the severity of the hypertensive changes in the ocular fundus, is sound, but it is not entirely applicable in evaluating surgical treatment, for both the patient with far advanced heart disease and the one with no cardiac involvement whatever may have angiospastic changes in the ocular fundi; 2 such cases should not be in the same category when one evaluates the effect of the operation on a category.

We have therefore classified the 437 cases in this series according to their general clinical profile, with the constitutional course of the disease forming the primary basis for classification:

Group 1. Early, mild hypertension. These patients were entirely asymptomatic, had normal or grade 1 fundi, and showed no evidence of cardiac, cerebral or renal involvement.

Group 2. Symptoms predominate. All patients in this group complained of symptoms and had abnormal fundi but displayed no evidences of cardiac, cerebral or renal impairment.

Group 3. Organic heart disease is predominant. In each case the diagnosis of heart disease was confirmed by either or both a definitely abnormal electrocardiogram and a teleoroentgenogram showing cardiac enlargement.

Group 4. Cerebrovascular disease is predominant. Each *patient in this group had one or more previous cerebral* accidents.

Group 5. Impaired renal function is predominant. Each patient showed diminished concentrating ability and urea clearance values.

Group 6. Malignant hypertension. These patients had severe neuroretinitis with definite papilledema of 1 diopter or more and displayed a rapidly progressive, downhill course.

METHOD OF STUDY

Each patient received an extensive preoperative workup. Detailed histories were taken and physical examinations performed in the departments both of medicine and of neurosurgery. Funduscopic examination through dilated pupils was done in the ophthalmology department. A teleoroentgenogram and electrocardiogram were obtained on each patient. Kidney function studies included the determinations of urea clearance, maximum concentrating ability and blood nonprotein nitrogen and urinalysis. Excretory pyelograms were done in a majority of the series; since 1939 this has been part of the routine preoperative procedure. The aim of the preoperative examinations is to rule out all specific causes of hypertension and to determine the constitutional extent of the hypertensive state in each case. Frequent blood pressure determinations were recorded in both arms with the patient sitting, standing and recumbent, and the readings were averaged.

Table 1.—*Sex Distribution*

20 to 29	33	7.6
30 to 39	120	27
40 to 49	208	48
50 to 59	69	15.8
63	1	0.2
Total cases	437	

Follow-up data were obtained largely through subsequent, periodic visits and reexamination as described. Of the 251 patients now living from the first 437 operated on and on whom we could obtain adequate postoperative data, 146 recently returned to the University Hospital for evaluation. Information on the remaining 105 living patients was obtained from both the patient and his home physician by letter. Information concerning the deceased patients was obtained from the referring physician and near relatives.

Table 3.—*Distribution of Preoperative Blood Pressure Levels*

Total cases	437	

The technic of bilateral supradiaphragmatic splanchnicectomy and lower dorsal sympathetic ganglionectomy has been described in detail.[5]

PREOPERATIVE DATA

From November 1933 to December 1940, 578 hypertensive patients were operated on by various members of the neurosurgery staff. The same technic was employed in all cases and a large majority of the operations were done by the same surgeon (M. M. P.). No adequate follow-up data could be obtained for 120 of these patients, leaving a series of 437 studied.

Fifty-two per cent of the 437 patients were females (table 1).

Ninety-two per cent of the series were 30 years or more of age, with 48 per cent in the fifth decade. The youngest patient was 10 years of age and the oldest was 63 (table 2).

The blood pressure levels in these patients were very high. Twelve per cent had blood pressures of 270/155 or greater. Seventy-three per cent had blood pressures above 210/125 (table 3).

One hundred and twelve patients, or 26 per cent of the series, had malignant hypertension (table 4); this diagnosis was made only when severe neuroretinitis with 1 diopter or more of papilledema was present together with a rapid, downhill course. Thirty-five per cent of the patients, not including any with malignant hypertension, had organic heart disease, confirmed either by a teleoroentgenogram showing definite cardiac enlargement or an abnormal electrocardiogram or both. Fifty-three patients, or 12 per cent, had previous cerebral accidents. Forty-one patients, or 9 per cent, had impaired kidney function by urea clearance and maximum concentration tests. The figures for the last two groups do not include those patients who had previous cerebral accidents or impaired kidney function with malignant hypertension, for all cases of malignant hypertension are in a separate group.

Table 4.—*Preoperative Classification*

Group	Number	Per Cent
1. Asymptomatic and early	5	1
2. Symptomatic, with no complicating disease	72	17
3.	154	35
4.	53	12
5.	41	9
6. Malignant hypertension	112	26
Total cases	437	

It is apparent that the hypertensive state in 82 per cent of the patients in this series had already progressed to serious organic illness prior to operation.

POSTOPERATIVE RESULTS

Adequate postoperative information was obtained on 437 of the 578 consecutive patients operated on from November 1933 to December 1940. Two hundred and fifty-one patients, or 57.5 per cent, are living five to eleven years after operation. The operative mortality was 3.6 per cent (table 5).

Of the 186 patients who died subsequent to the operation, 91 had malignant hypertension (table 6). Thus 81 per cent of the preoperative group with malignant hypertension have not survived five to eleven years. Approximately one third of each of the preoperative groups with organic heart disease, cerebrovascular disease and impaired renal function are dead. All of the 5 patients with early, mild, asymptomatic hypertension are still living, and 95 per cent of the 72 patients in group 2 of our classification are alive five to eleven years after operation.

Our findings substantiate the long-known fact that hypertensive disease is of much more serious import in the male than in the female (table 7). One hundred and seventeen males died; these constitute 62 per cent of the total deaths and 56 per cent of the total number of males in the series. Only 30 per cent of the total number of females subsequently died.

---

[5] Peet, M. M.: The Surgical Treatment of Hypertension, California Acad. Med. 5: 58, 1935-1936.

The age of the patient at the time of operation has no influence on survival. The distribution of deaths according to preoperative age is exactly comparable to the preoperative age distribution for the entire series (table 8). As has been pointed out before, it is the preoperative extent of constitutional involvement by hypertensive disease that influences length of postoperative survival.

EFFECT OF SURGICAL TREATMENT ON BLOOD PRESSURE LEVELS

The 251 patients living five to eleven years after operation have obtained and maintained significant blood pressure reductions (table 9). In 20.3 per cent blood pressure has been reduced to normal. The upper limits of normal blood pressure have been arbitrarily placed at 140/90 for ages up to 40 and at 150/95 for ages over 40. There has been definite reduction, but not to normal levels, of more than 80 mm. systolic and 25 mm. diastolic, in another 26 per cent of the living patients. Significant reduction, of more than 40 mm. systolic and 15 mm. diastolic, occurred in 35 per cent. Of the living patients 18.7 per cent showed either no significant change or increase in blood pressure.

TABLE 5.—*Postoperative Data*

	Number	Per Cent
Total cases with adequate postoperative information	437	
Total living 5 to 11 years after operation	251	57.5
Total deaths subsequent to operation	186	42.5
Operative mortality in 578 consecutive operations from November 1933 to December 1940	21	3.6

TABLE 6.—*Subsequent Deaths According to Preoperative Classification*

Group	Number	Per Cent of Total Deaths	Per Cent of Preoperative Group
1	0	0	0
2	4	2	5
3	59	32	38
4	19	10	36
5	13	7	32
6	91	49	81
Total	126		

This high percentage of good results among the living patients grantedly is enhanced by the fact that the poor results have been eliminated by death. Yet when all the deaths in the series are included, the effect of the operation on blood pressure levels still remains significantly effective. Of the entire series 46.7 per cent show significant reduction in blood pressure five or more years after operation. The latter computation suggests that all patients who died subsequent to surviving five postoperative years manifested no beneficial effect on blood pressure levels after the fourth postoperative year. Actually this was not so. Thirty-two patients survived five years and subsequently died during their sixth to tenth postoperative years; several of these maintained significant reduction in blood pressure during the intervening years between operation and terminal illness. Nevertheless, in our statistical analyses these 32 cases are not segregated from the overall group of 186 deaths even though they were "five year survivals."

Of the 5 patients in group 1, with mild and asymptomatic hypertension, 4 have maintained normal blood pressure and 1 has maintained a definite reduction for five years and more (table 10). Of all patients in group 2 who had symptoms and fundus changes but no cardiac, cerebral or renal impairment, 77.2 per cent maintained normal, definitely reduced and significantly reduced blood pressure levels for five years and more. Similar blood pressure reductions were shown by 48 per cent of those with organic heart disease, 52.8 per cent with cerebrovascular disease and 58.4 per cent with renal impairment. Of the patients with preoperative malignant hypertension 16 per cent maintained significant blood pressure reductions for five years and more.

TABLE 7.—*Subsequent Deaths According to Sex*

	Number	Per Cent of Total Deaths	Per Cent of Total of Same Sex
Males	117	62	56
Females	69	38	30
Total deaths	186		

TABLE 8.—*Comparison of Preoperative Age Distribution and Distribution of Deaths According to Preoperative Age*

Peroperative Age	Preoperative Distribution		Distribution of Deaths	
	Number	Per Cent	Number	Per Cent

63	1	0.2	..	....
Total cases	437		186	

It is thus seen that the patient whose hypertensive state has not yet progressed to evident involvement of the heart, cerebral arteries or kidneys stands an excellent chance for prolonged blood pressure reduction from surgical treatment. Nevertheless a remarkable percentage of patients with organic heart disease, cerebrovascular disease and renal impairment have maintained significant blood pressure reductions for long periods of time.

TABLE 9.—*Effect of Surgical Treatment on Blood Pressures in 251 Patients Living Five to Eleven Years After Operation*

	Number of Cases According to Preoperative Classification						Per Cent of Living Patients		Per Cent of Total Series, Living and Dead	
	1	1	3	4	5	6				
Reduced to normal (140/90 for ages up to 40) (150/95 for ages over 40)	4	21	9	9	6	2	20.3	81.3	11.7	46.7

Increased	..	3	7	2	2	1	6			
Total cases	5	68	95	34	28	21				

It may justifiably be assumed that, if a patient had significantly reduced blood pressure at an examination in the seventh or eleventh postoperative year, the reduction had been maintained over the entire postoperative period. Many of the patients in this series have returned to the University Hospital for periodic checkup examinations and for the previous surveys of this series; those who now have significant blood pressure reductions have repeatedly demonstrated this on previous examinations.

Total cases....	186	

EFFECT OF SURGICAL TREATMENT ON HYPERTENSIVE SYMPTOMS

The beneficial effect of surgical treatment on hypertensive symptoms is an established and accepted result. This therapeutic measure must always be considered in the management of hypertensive patients with severe, incapacitating headaches, dizziness, fatigability, epistaxis, urinary frequency and nocturia, nausea and vomiting, or blurring of vision. For these symptoms bilateral supradiaphragmatic splanchnicectomy offers a definite opportunity for relief.

TABLE 12.—*Effect of Surgical Treatment on Symptomatology in 251 Patients Living Five to Eleven Years After Operation*

Preoperative Status	Total	Postoperative Result: Complete Relief	Definite Improvement	Moderate Improvement	Unchanged	Worse
No significant symptoms						
Number....	8	..	..	..	8	
Per cent....	..	..	..	..	(100%)	
Moderate symptoms						
Number....	67	14	30	14	5	4
Per cent....	..	(21%)	(44.5%)	(21%)	(7.5%)	(6%)
Severe, incapacitating symptoms						
Number....	176	47	81	36	7	5
Per cent....	..	(27%)	(46%)	(20%)	(4%)	(3%)
Total cases....	251					

Of 176 patients who had severe, incapacitating symptoms before operation, 27 per cent were maintaining complete relief five to eleven years later, another 46 per cent felt definitely improved and only 7 per cent were unchanged or worse (table 12). Of 67 patients who had moderate hypertensive symptoms preoperatively 21 per cent now were enjoying complete relief, another 65.5 per cent were definitely or moderately improved and 13.5 per cent were unchanged or worse.

The foregoing statistics do not include the 186 deceased patients in the series. Information obtained from referring physicians and near relatives shows that 22 per cent of the 186 dead obtained definite symptomatic relief during the interval between operation and terminal illness (table 11), 26 per cent obtained moderate relief and 29 per cent no relief. No data were obtained on the remaining 23 per cent.

It is apparent that patients who live a long time after the operation continue to obtain symptomatic benefit during all that time. Relief from the distressing symptom of hypertensive headache is most striking. To observe the previously incapacitated patient return to gainful occupation several months after the operation and still continue at full time work five to eleven years later is most gratifying.

EFFECT OF SURGICAL TREATMENT ON EYEGROUNDS

Of the 251 living patients in the series, only 146 received a recent funduscopic examination five to eleven years postoperatively (table 13). Eleven had normal fundi preoperatively, and all 11 retained this status over the long postoperative period. Thirty patients showed sclerotic changes only of the retinal arterioles, and 83.3 per cent of these remained unchanged while 10 per cent progressed to worse changes. Of the 88 patients who had angiospastic retinitis with or without sclerosis and with or without hemorrhages and exudates preoperatively, 82 per cent were improved in that localized vasospasms had disappeared and no new hemorrhages or exudates had occurred; 17 per cent of these 88 patients remained unchanged and 1 was worse.

TABLE 13.—*Effect of Surgical Treatment on Eyegrounds of 146 Patients Living Five to Eleven Years After Operation*

Preoperative Status	Cases	Postoperative Result: Improved	Unchanged	Worse
1. Normal fundi....	11	....	11 (100%)	....
2. Sclerosis only....	30	2 (6.7%)	25 (83.3%)	3 (10%)
3. Angiospastic retinitis, with or without hemorrhages and exudates....	88	72 (82%)	15 (17%)	1 (1%)
4. Papilledema	17	17 (100%)		
Total cases....	146			

Twenty-one of 112 preoperative patients with malignant hypertension with severe neuroretinitis and 1 diopter or more of papilledema are still living five to eleven years after operation and 17 received recent funduscopic examination. In all these 17 patients the papilledema had disappeared.

This evaluation of the influence of splanchnicectomy on the ocular fundi in hypertension does not include the 186 deceased patients of the series. Thus from the foregoing statistics one must come to no further conclusion than that among the patients living five to eleven years after operation a remarkably high percentage of those who had had angiospastic retinitis, hemorrhages, exudates or papilledema have maintained funduscopic improvement over the long postoperative period. Greatest improvement occurred in those with preoperative angiospastic retinitis, for it is common for localized vasospasm to disappear postoperatively. On the other hand, sclerosis of the retinal arterioles is a permanent change; the effect of splanchnicectomy in these cases is to limit further progression for all but a small percentage.

EFFECT OF SURGICAL TREATMENT ON THE HEART IN HYPERTENSION

Of the living patients 141 had recent electrocardiograms taken (table 14). Of the 84 patients whose electrocardiograms were normal preoperatively 93 per cent maintained an unchanged, normal electrocardiogram five to eleven years after operation; in only 7 per cent did the electrocardiogram become abnormal. Of the 57 patients who had abnormal preoperative electrocardiograms 52.7 per cent showed significant improvement five to eleven years later, consisting of significant left axis deviation returning to normal or of previously inverted T waves in leads 1 or 2 returning to normal. Of the abnormal electrocardiograms 42 per cent showed no significant change, while 5.3 per cent progressed to worse changes.

Of 80 living patients with normal heart size preoperatively, 91.2 per cent maintained normal heart size by comparative teleoroentgenograms five to eleven years later; 7 patients, or 8.8 per cent, had significant increase in heart size (table 15). Forty-eight living patients had preoperative cardiac enlargement of 18 per cent or more above the predicted normal area. Twenty-five, or 52 per cent, of these patients with enlarged hearts showed significant reduction in heart size. Sixteen of these 25 had had slight cardiac enlargement of 18 to 30 per cent above predicted normal area, and in each instance the teleoroentgenogram five to eleven years after operation showed no cardiac enlargement; the remaining 9 patients had had moderate cardiac enlargement of 30 to 75 per cent above the predicted normal area preoperatively, and each showed significant reduction in size to only slight cardiac enlargement. Only 4.2 per cent of the living patients with preoperative cardiac enlargement now show further increase in heart size.

TABLE 14.—*Effect of Surgical Treatment on the Electrocardiogram in 141 Living Patients Five to Eleven Years After Operation*

		Postoperative Status		
Preoperative Status	Cases	Significantly Improved	No Significant Change	Worse
Normal electrocardiogram.......	84	....	78 (93%)	6 (7%)
Abnormal electrocardiogram....	57	30 (52.7%)	24 (42%)	3 (5.3%)
Total cases....................	141			

It is remarkable that, of the patients who had heart disease before operation and who are still alive, more than half maintain significant improvement in their electrocardiograms and significant decrease in heart size. But splanchnicectomy has not benefited such a great percentage of the entire group of 154 patients who had organic heart disease prior to operation. Thirty-eight per cent of this group were dead in 1945. In addition, many of the patients who had malignant hypertension subsequently died in congestive heart failure.

Splanchnicectomy has possibly prevented progression to organic heart disease in hypertensive patients who manifested no evidence of cardiac involvement preoperatively. Of 87 patients who did not have heart disease prior to operation, 79 still showed no evidence of heart disease five to eleven years later; only 9 per cent subsequently developed heart disease.

EFFECT OF SURGICAL TREATMENT ON CEREBROVASCULAR DISEASE

There are still living five to eleven years after operation 48 of a total of 73 patients who had had definite cerebral accidents prior to operation. Forty-three of the 48 have had no subsequent cerebral accidents during the long postoperative period. It thus appears that splanchnicectomy affords some protection against subsequent cerebral accidents in those hypertensive patients who have had this unfortunate complication.

TABLE 15.—*Effect of Surgical Treatment on Heart Size, Measured by Teleoroentgenogram, of 128 Living Patients Five to Eleven Years After Operation*

		Postoperative Result		
Preoperative Status	Cases	Significant Decrease in Heart Size	No Significant Change	Increase in Heart Size
Normal heart size................	80	....	73 (91.2%)	7 (8.8%)
Cardiac enlargement (18% or more above predicted normal area)........................	48	25 (52%)	21 (43.8%)	2 (4.2%)
Total cases....................	128			

Of the 437 patients in this series, 61 have died of cerebrovascular disease. Twenty-five of these deaths occurred in persons who had had preoperative cerebral accidents, and 13 of the 25 also were cases of malignant hypertension. Thirty-six deaths from cerebrovascular disease occurred of patients with no preoperative clinical evidence of such involvement, but 20 were cases of malignant hypertension.

EFFECT OF SURGICAL TREATMENT ON KIDNEY FUNCTION

An eighteen hour concentration test of kidney function[6] was performed recently on 117 of the living patients five to eleven years after operation. Sixty-two of these patients had normal kidney function before operation, and 51 of these have maintained normal concentrating ability for the long period of time since operation; 11 patients have manifested impaired concentrating power since operation (table 16).

Of 55 patients who had impaired kidney function prior to splanchnicectomy 20, or 36.4 per cent, have shown significant improvement in concentrating ability five to eleven years later; 52.6 per cent showed no change, and 11 per cent are worse.

TABLE 16.—*Effect of Surgical Treatment on Renal Concentrating Ability of 117 Patients Living Five to Eleven Years After Operation*

		Postoperative Result		
Preoperative Status	Cases	Significant Improvement	No Change	Worse
Normal function............	62	....	51 (82.3%)	11 (17.7%)
Impaired function..........	55	20 (36.4%)	29 (52.6%)	6 (11%)
Total cases.............	117			

It appears that a considerable percentage of patients with preoperative impaired kidney function have maintained significant improvement of kidney function during the long period of time since operation. Of the 186 deaths in the series, 21 were caused by uremia.

EFFECT OF SURGICAL TREATMENT ON THE LIFE HISTORY OF ESSENTIAL HYPERTENSION

The ultimate test of the value of surgical treatment is whether it significantly alters the inevitable, progressive, fatal course pursued by the great percentage of cases of essential hypertension. Now that a series of surgically treated hypertensive patients has been followed for a long time, fair comparisons can be made with the several series of medically treated cases in the literature.

In Janeway's[7] series of 458 patients, one half of the males had died within four years and one half of the females within five years of the time of development of symptoms; by the tenth year half of the remainder had died. Hamman[8] had a mortality of 30 per cent at the end of five years and 78 per cent at the end of ten years.

King, Carlile and Blackford[9] followed 481 patients for ten to sixteen years, and the mortality was 73 per cent. In half of the cases in their series the discovery of hypertension was purely an incidental finding.

Five years ago Woods and Peet[10] compared 76 patients (included in the present report) who were then alive five to seven years after operation with the series of Keith, Wagener and Barker.[4] The present, larger group of 437 patients followed for a longer time compares just as favorably as the smaller group did five years ago. One hundred and forty-six, or 62 per cent, of the 219 patients in the Keith-Wagener-Barker series had malignant hypertension, while 112, or 26 per cent, of our 437 patients had malignant hypertension; theirs is a more seriously ill group. Only 19 patients, or 8.6 per cent, of their series were alive five to nine years after the first examination. Of our 437 patients 57.5 per cent are living five to eleven years after operation. Our survival rate thus also compares very favorably with that of Janeway, of Hamman and of King, Carlile and Blackford. At the end of five postoperative years, 64.8 per cent of our patients were living.

TABLE 17.—*Causes of Death Up to Eleven Years After Operation of 186 Surgically Treated Patients with Essential Hypertension*

	Number	Per Cent
Congestive heart failure	66	35.4
Cerebrovascular accident	61	32.8
Uremia	21	11.3
Coronary occlusion with myocardial infarction	16	8.6
Dissecting aneurysm of aorta	2	1.1
Causes other than hypertension	10	5.4
Cause unknown	10	5.4
Total cases	186	

It is in malignant hypertension that fair comparisons can be made between our present series and the Keith-Wagener-Barker series. Twenty-one patients, or 19 per cent, of our 112 with malignant hypertension treated surgically are alive five to eleven years after operation. Of the 146 patients with malignant hypertension in the Keith-Wagener-Barker control series 79 per cent were dead at the end of the first year, 88 per cent at the end of the second year, 94 per cent at the end of the third year, 98 per cent at the end of the fourth year and 99 per cent at the end of the fifth year. Only 1 patient with malignant hypertension in the control series survived five years.

Surprisingly, the cases of malignant hypertension in the surgically treated series of de Takáts, Heyer and Keeton[11] did not respond with any benefit. They, just as the Keith-Wagener-Barker control series, had a five year mortality of 99 per cent. They even list malignant hypertension as a contraindication to surgical treatment. Allen and Adson[12] also stated that malignant hypertension does not respond satisfactorily to surgical treatment. We have found that there is hope of prolonged survival for 19 per cent of the patients with malignant hypertension surgically treated. We firmly feel that no patient with malignant hypertension, otherwise suitable for operation, should be denied this 1 chance in 5 to prolonged life of more than five years, compared to the one chance in 146 offered by general medical management.

It appears from comparison of survival statistics that the life span of the hypertensive patient may be significantly lengthened by surgical treatment.

Fifty-one patients in this series have maintained blood pressure levels within normal limits for five to eleven years since operation; 28 show no evidence whatever of hypertensive disease at the present time. These 28 persons not only have maintained normal blood pressure levels, but also they are completely free from symptoms, their eyegrounds are either normal or show only sclerotic changes, and they manifest no evidence of cardiac, cerebral or renal involvement. These 28 persons could be termed "five year cures"; actually we have never made claims that essential hypertension could be cured by splanchnicectomy. The hypertensive predisposition always persists following surgical treatment, regardless of the fall of blood pressure to normal levels.

COMMENT

The foregoing information obtained from observing a large group of surgically treated hypertensive patients over a long period of time should enable more accurate identification of the patients who may obtain good results from operation. The postoperative data have been presented in a manner so that one may now know what to expect from splanchnicectomy in the individual case selected for operation.

Intelligent management of a case of essential hypertension requires a knowledge of the complete clinical profile of the patient. The workup of the patient must include in addition to the routine history and physical examination an ophthalmoscopic examination, electrocardiogram, teleoroentgenogram, excretory pyelogram and kidney function studies. The patient should be followed by checking on these various aspects of hypertensive disease from time to time. Then one may know whether or not the hypertensive state in a given case is progressive in nature. The patient whose hypertensive disease shows evidence of progression and activity is a candidate for surgical treatment.

It is well known that there is a group of persons who tolerate essential hypertension exceedingly well. They live out a normal life span without any symptoms or complicating accidents of hypertensive disease. Naturally, this group needs no active treatment.

When elevated blood pressure is discovered as an incidental finding, a complete hypertensive study of the patient is indicated. If the blood pressure is only moderately elevated and there are no symptoms, no fundus abnormality and no cardiac, cerebral or renal involvement, management of the patient by general medical measures and periodic examination is advisable. If evidence of progression is discovered—such as hypertensive symptoms, or angiospastic-retinal changes or cardiac, cerebral or renal involvement—the patient has become a candidate for surgical treatment. No form of medical therapy has yet been shown to be as efficacious as surgical treatment in arresting the pernicious, progressive character of hypertensive disease, promoting improvement and increasing life span.

It has been shown that hypertensive patients with symptoms and fundus changes, but no evidence of cardiac, cerebral or renal involvement—group 2 of our classification—may expect excellent results from surgical treatment. Ninety-five per cent of the patients in this category were living five to eleven years after operation; the five year survival rate was 98.6 per cent, for three of the four deaths in this group occurred subsequent to the fifth postoperative year. Three of the four deaths in this group were from causes other than hypertensive disease, and all 3 patients had maintained normal blood pressure levels until death occurred. One of the 3 deceased patients passed an army final-type physical examination and was commissioned; he maintained a normal blood pressure during two and one half years of rigorous infantry training, and he was killed by a German sniper while at his regimental command post on a Normandy beachhead. The second died of acute intestinal obstruction, and the third died of carcinoma of the testis with metastasis.

Thirty per cent of the patients in group 2 have maintained normal blood pressure levels, and another 47 per cent have maintained definite or significant reductions. Symptoms have been completely relieved or definitely improved and angiospastic-retinal changes have been improved in remarkably high percentages. Their normal electrocardiograms, heart size and kidney function have been adequately protected.

Approximately one third of all the patients who showed preoperative evidence of either organic heart disease, cerebrovascular disease or impaired kidney function did not survive five to eleven years. Evidence of involvement of any one of these vital organ systems is indicative of generalized vascular involvement. Hypertensive heart disease is not to be considered singularly; it is a part of a constitutional disease. Not all patients with hypertensive heart disease die in congestive failure; many die of a cerebrovascular accident and some in uremia. The patient who has had a cerebral accident may later die of a cardiac lesion.

Half of the patients in preoperative groups 3, 4 and 5 may expect significant blood pressure reductions maintained for at least five to eleven years. Their hypertensive symptoms—such as headache, dizziness, tinnitus, epistaxis, fatigability, weakness, nocturia, nervousness, irritability and blurring of vision—and retinal angiospasms are relieved in the same high percentages as in group 2. Of those who had abnormal electrocardiograms and cardiac enlargement before operation and are still living, more than half have maintained significant improvement of these objective aspects for five to eleven years.

Sixty per cent of patients who have suffered a cerebral accident may expect prolonged life with no subsequent cerebral accident after splanchnicectomy.

Nineteen per cent of the 112 patients with preoperative malignant hypertension are living five to eleven years later. Eighteen of these 21 living patients are maintaining significant reductions in blood pressure. Seventeen of these patients received funduscopic examinations, and papilledema had disappeared in all. In the survivors, symptomatic improvement has been remarkable. Splanchnicectomy offers hope for prolonged life to 1 out of every 5 patients with malignant hypertension.

Any patient who is under 60 years of age, who is not in congestive heart failure, whose blood nonprotein nitrogen level is below 45 mg. per hundred cubic centimeters and who has not sustained a major cerebral accident during the previous month may be considered as a reasonable operative risk.

The age of the patient at time of operation has no influence on postoperative survival. The extent of the hypertensive disease process is the important factor in survival.

SUMMARY

Four hundred and thirty-seven patients with essential hypertension have been followed since receiving the surgical treatment of bilateral supradiaphragmatic splanchnicectomy and lower dorsal ganglionectomy five to twelve years ago.

Two hundred and fifty-one patients, or 57.5 per cent of the series, are living five to eleven years after operation. At the end of five postoperative years 64.8 per cent of the entire series was alive. The hypertensive state in 82 per cent of the patients in this series had already progressed to serious organic disease prior to operation.

Fifty-six per cent of all the males have died, while the female mortality was only 30 per cent.

Ninety-five per cent of hypertensive patients who showed no preoperative evidence of cardiac, cerebrovascular or renal involvement are living five to eleven years after operation.

Approximately one third of all patients who manifested preoperative evidence of organic heart disease, cerebrovascular disease or impaired kidney function did not survive five to eleven years.

Nineteen per cent of 112 patients with preoperative malignant hypertension are living five to eleven years later.

Fifty-one patients have maintained normal blood pressure levels and 28 show no evidence whatever of hypertensive disease five to eleven years after operation.

Significant reductions in blood pressure, complete and definite symptomatic relief, improvement of eyegrounds and improvement of abnormal electrocardiograms, cardiac enlargement and kidney concentrating ability have been maintained for five to eleven postoperative years in a remarkable percentage of patients.

Sixty per cent of patients who had previous cerebral accidents suffered no recurrence during the long postoperative period.

Surgical treatment is a measure to be considered in the management of every case of essential hypertension, but to be utilized only when indicated. Evidence of progression and activity of hypertensive disease constitutes indication for surgical treatment.

EFFECT OF FOLIC ACID ON PERSONS WITH MACROCYTIC ANEMIA IN RELAPSE

TOM D. SPIES, M.D.
Birmingham

That macrocytic anemia in relapse is promptly relieved by either the parenteral or the oral administration of synthetic folic acid was reported by Spies, Vilter, Koch and Caldwell[1] in November 1945. The following month Vilter, Spies and Koch[2] reported another series of cases in which these results were confirmed. At the same time Spies, López, Menéndez, Minnich and Koch[3] reported that the macrocytic anemia of tropical sprue found in Cuba responds in a similar manner.

The present report, which is a tentative evaluation of the status of folic acid as a therapeutic agent, is presented because of the large number of requests for information from physicians regarding the use of folic acid as a therapeutic agent. It has been disheartening to write to so many physicians that leukemia, aplastic anemia and some of the anemias of undetermined origin do not respond specifically to this substance.

The present communication is based on my observations of the effect of folic acid in anemia. These observations were made on patients in Birmingham, Ala., and in Havana, Cuba. All except 2 of the patients were studied in conjunction with one or more of the associates mentioned.

In selecting the cases, the following criteria were used: 1. The patient must have a macrocytic anemia with red blood cell counts of 2.5 million or less and a color index of over 1. 2. He must be untreated, or he must not have been treated recently enough to interfere in any way with our evaluation of the effect of folic acid. 3. He must not have any complicating disease which might be lethal during the course of the study. 4. The bone marrow must contain megaloblasts and have the typical erythroblastic arrest seen in macrocytic anemia. A fifth criterion used for the selection of any patient in Cuba, where we were studying sprue, was that he must have "fatty stools" and weight loss.

With these criteria in mind, we selected for special study a group of 45 patients. This group included 8 patients with so-called nutritional macrocytic anemia, 8 with pernicious anemia, 11 with sprue, 3 with anemia associated with pregnancy, 1 with anemia associated with carcinoma, 1 with anemia associated with chronic alcoholic addiction, cirrhosis of the liver and neuritis, 3 with anemia of undetermined origin, 3 with aplastic anemia, 3 with anemia associated with leukemia and 4 with iron deficiency anemia.

The diagnoses of the patients shown in the accompanying table were arrived at after intensive study by a number of physicians. The clinical separation of these various syndromes is somewhat arbitrary; but in view of the findings reported in this paper and in our previous publications on folic acid, the classification probably is not of as great importance as it has been considered in the past. As far as possible, the cases are classified arbitrarily in order to aid other investigators who may wish to study the effect of folic acid on similar patients.

Forty-one of the 45 patients had typical macrocytic hyperchromic anemia diagnosed on the basis of criteria used in the past in the Nutrition Clinic at Hillman Hospital.[4] The other 4 patients had iron deficiency anemia characterized by a low color index. A diagnosis of pernicious anemia was made only when there was no free hydrochloric acid, pepsinogen or rennin in the gastric juice after histamine stimulation. A diagnosis of sprue was made only in the presence of steatorrhea. If pregnancy was the only etiologic agent present, a diagnosis of macrocytic anemia of pregnancy was made. If the patient had a blood picture typical of macrocytic anemia and if there was free hydrochloric acid, pepsinogen and rennin in the gastric juice, a diagnosis of nutritional macrocytic anemia was made. In most instances there was complete agreement on the part of the physicians with regard to the clinical classification of these cases. The cases in which there was a difference of opinion were classified as indeterminate.

Pellagra, which was diagnosed only in the presence of characteristic tongue or dermal lesions, was present at the time folic acid therapy was initiated in 7 cases: 1 (case 3) of nutritional macrocytic anemia, 2 (cases 7 and 10) of pernicious anemia, 2 (cases 17 and 19) of sprue, 1 (case 21) classified as indeterminate and 1 (case 24) of macrocytic anemia of pregnancy. In 2 of the cases of pernicious anemia, neurologic alterations indicative of mild postolateral sclerosis were present. In the group of cases classified as nutritional macrocytic anemia, severe polyneuritis was present in 1 and mild peripheral neuritis in 2. In 2 of the cases of sprue there was also evidence of peripheral nerve involvement.

All except 4 of the patients were hospitalized for preliminary observations, base line determinations and treatment. Four of the patients who lived near the Nutrition Clinic in Birmingham were treated as ambulatory cases. They came to the clinic daily throughout the study. A detailed medical and dietary history was obtained and a careful physical examination was made in each case. During the control period and also during the period of most active regeneration, red and white cell counts, reticulocyte counts and hemoglobin determinations were made daily.[3] Thereafter these determinations were made at increased intervals. Bone marrow studies were also made in each case.

The diet of 35 of the 41 hospitalized patients was rigidly controlled during the whole period of study. Meat, meat products, fish and poultry were excluded, and only 1 quart of milk and one egg daily were allowed. Bread, cereals, sugar, fats and vegetables were permitted in any amount desired. In a previous study of anemia, 75 patients had been restricted to this diet, and not 1 of them had had a so-called spontaneous remission. We felt certain, therefore, that any hemopoietic response by the patients on folic acid therapy would be attributable to the folic acid rather than to the foods included in the diet. The other 6 hospitalized patients (the 3 with leukemia and the 3 with aplastic

---

The folic acid for the study was supplied by Lederle Laboratories, Inc.

The expenses of this study were borne by grants from the Lederle Laboratories, Inc., and the Edward Mason Williams Fund.

University of Cincinnati Studies in Nutrition at Hillman Hospital, Birmingham, Alabama, and at the Calixto García Hospital, Havana, Cuba, in cooperation with the Institute of Nutrition of Cuba, the Coordination Committee for Cuba and the University of Havana.

anemia) were given the usual hospital diet ad libitum. The 4 ambulatory patients ate their meals at home. However, because of financial limitations these 4 persons were unable to vary their diets to any extent from day to day and, according to their dietary histories, the food they ate at home was similar to that eaten by the patients on the controlled diet. As soon as the studies were completed, each patient was advised to eat a liberal, well balanced diet including lean meat, eggs and milk.

Effect of Folic Acid on Peripheral Blood in Macrocytic Anemia

* In case 9 the initial red blood cell count is interpreted as being in error since it is out of line with the other determinations. At any rate the blood responded following treatment.

The diet of 2 patients with pernicious anemia and pellagra had been inadequate for many years. Of the other 3 patients with pernicious anemia the diet had been well balanced and, as a rule, adequate, although in some instances the total food intake had been reduced because of loss of appetite. This was true also of the patients with aplastic anemia, leukemia, cirrhosis of the liver and carcinoma. An adequate diet had been available to all the patients with macrocytic anemia of pregnancy, but vomiting and loss of appetite had caused them to reduce their food intake far below the desired level. In every case of nutritional macrocytic anemia, in every case of sprue and in the 3 indeterminate cases the diet had been grossly inadequate for several years. Although some of the patients included in this study live in Alabama and others live in Cuba, an analysis of their diets showed that, while the types of foods differed somewhat in the two countries, the nutritional quality of the diets of the two groups was strikingly similar. In both groups the diets tended to be low in animal proteins, minerals and vitamins, high in concentrated carbohydrates and relatively high in fat.

All the patients complained of loss of strength, vigor and appetite, and in most instances there had been a considerable loss of body weight. The diarrhea of the patients with sprue was characterized by stools which ranged in frequency from five to twenty times daily. The stools were yellow or white, watery, foamy and foul in odor. When diarrhea was present in cases other than sprue, the stools were watery and brownish, and the odor was not particularly foul. All the patients with diarrhea stated that it was more severe after meals.

The folic acid was administered either parenterally or orally. In 2 cases it was administered intramuscularly and in 6 cases intravenously. In order to get the folic acid into solution for parenteral administration, we converted it into a soluble salt by adding a normal sodium bicarbonate solution. To insure sterility the solution was then passed through a Seitz filter. When the folic acid was given orally in amounts of 20 mg. or more a day, one half the total dose was given in the morning and the other half in the afternoon. For oral administration each dose was prepared by mixing the folic acid to a smooth paste with four or five drops of cold water and then adding 20 cc. of cold water while the mixture was stirred constantly. After the patient drank this material, a small amount of water was used to rinse the glass thoroughly, and the patient drank this also to insure his getting as much of the folic acid as possible.

The laboratory findings and the response to folic acid therapy can be seen in the table, in which the results in 27 cases are shown. Data on 18 patients are not included in the table: 3 with aplastic anemia, 4 with iron deficiency anemia and 3 with the anemia associated with leukemia, none of whom responded to folic acid therapy; 5 patients[5] in whom we were attempting to establish the minimal dosage of folic acid and who did respond satisfactorily though perhaps not maximally on the amount administered (study of these cases is being continued, but it is too early to present data on them), and 3 patients with sprue who, we noted during the preliminary period of observation, were having a hemopoietic response. These 3 patients denied having had antianemic therapy recently, but on further questioning we found that they had been treated although they did not realize that they had received treatment for anemia. This indicates the importance of making base-line determinations in every case. Because these 3 persons had received antianemic therapy recently, they were not given folic acid at this time.

The results presented in the table show that only 1 of the patients included (patient 2) failed to respond to folic acid in amounts above 10 mg. a day. Although this patient is classified as having nutritional macrocytic anemia, a satisfactory diagnosis has never been made despite the fact that she has been seen by many competent physicians. The patient is still under observation in an endeavor to obtain more exact hematologic information.

The white blood cell counts of patients with nutritional leukopenia are not shown in the table. The white blood cells also tended to increase following the administration of synthetic folic acid. Early observations on this study were reported recently by Berry, Spies and Doan[6] and by Vilter, Spies and Koch.[2]

Prompt improvement occurred in the general condition of 26 of the 27 patients reported in the table. On the third or fourth day following the initiation of folic acid therapy these 26 patients volunteered that they felt stronger. At the same time there was a definite improvement in their appetites: those under observation in the hospital began eating all the food on their trays and frequently asked for additional servings, and those who were being treated as ambulatory patients and who ate their meals at home voluntarily told us that they had a similar improvement in appetite. This subjective improvement coincided with or was followed by an increase in the reticulocytes in the peripheral blood and by subsequent rises in the red blood cells and in the hemoglobin content of the blood. The reticulocytes began to rise on the third, fourth, fifth or sixth day of folic acid therapy and reached a peak on the sixth, seventh or eighth day. This improvement occurred regardless of the mode of administration.

It is of considerable interest that the case of macrocytic anemia associated with chronic alcoholic addiction, cirrhosis of the liver and peripheral neuritis (case 26) and the case of macrocytic anemia associated with carcinoma of the stomach with metastasis to the lungs (case 27) each showed a significant hemopoietic response following folic acid therapy.

In the patients with aplastic anemia, leukemia and iron deficiency, no improvement could be detected either clinically or by means of laboratory determinations.

SUMMARY AND CONCLUSIONS

These findings and others that my associates and I have reported show that synthetic folic acid administered either parenterally or orally is effective in producing a significant hemopoietic response in persons with nutritional macrocytic anemia, or with the macrocytic anemias of pellagra, of pernicious anemia, of sprue or of pregnancy. This hemopoietic response is characterized by an increase in reticulocytes, red blood cells, white blood cells, platelets, normoblasts and hemoglobin. The megaloblasts in the bone marrow are decreased following therapy.

It is worthy of emphasis that none of the patients with aplastic anemia, iron deficiency anemia or the anemia associated with leukemia showed any improvement. We have found that folic acid corrects the leukopenia of certain nutritional conditions but does not correct the leukopenia of a number of infectious diseases or idiopathic states.

The subjective and the objective improvement which follows the administration of folic acid to persons with macrocytic anemia in relapse is similar to that which follows liver extract therapy. There is a tremendous upsurge of well-being, an increase in strength and vigor, a return of appetite and a desire to walk about. It is too early in our studies to know whether or not folic acid is as effective as liver extract in maintaining the blood levels or in protecting against combined system disease.

The exact minimal and optimal doses of folic acid have not been determined, but our studies indicate that there is some variation from patient to patient. Although we have found that the administration of as much as 400 mg. daily has not caused any untoward symptoms, a daily dosage of from 5 to 10 mg. parenterally or some 10 mg. by mouth will often produce a maximum hemopoietic response. In order to determine the optimal and the average doses, the study of many patients will be required. The response of 5 patients to a daily dosage of 10 mg. by mouth may be an indication that the average doses, when they are finally determined, will be lower than those we are suggesting at this time.

[5] Unpublished observations by Tom D. Spies, Carl F. Vilter and Richard W. Vilter.

[6] Berry, L. Joe; Spies, Tom D., and Doan, Charles A.: A Note on the Influence of "Folic Acid" on Leukocyte *Equilibrium in Malnourished* Patients, South. M. J. **38**: 590-592 (Sept.) 1945.

Unpublished observations of mine have shown that dried brewers' yeast powder, yeast concentrate or liver extract produces a response in persons with macrocytic anemia in relapse, a response which is out of proportion to the folic acid content of these substances. A number of patients have failed to respond fully to folic acid at the level of 3 or 4 mg. per day by mouth and have responded to liver extract or yeast administered in amounts which supply 1 mg. or less of folic acid daily. These findings suggest that the antianemic factor present in liver extract or yeast may be a combination of chemical substances or that it may be a much larger molecule than folic acid. From a practical point of view it must be stressed, however, that folic acid administered either orally or parenterally will give a satisfactory response in patients with macrocytic anemia.

I have studied 2 additional patients with macrocytic anemia who have developed such severe sensitivity to various forms of liver extract that they were unable to tolerate injections in sufficient amounts to maintain proper blood values. In both cases folic acid was substituted for the liver extract safely and satisfactorily.

It must be stressed that neither folic acid nor any other single chemical substance can be expected to take the place of all the nutrients essential for health. The patients in this study were given a restricted diet in order to test more effectively the antianemic properties of folic acid. A restricted diet is not recommended in the treatment of macrocytic anemia. On the contrary, we prescribe a diet high in protein, minerals and vitamins.

The laboratory observations obtained from frequent examinations of stools and bone marrows will form the basis of a separate report. Suffice it to say that the stools and the bone marrow both tend to approach normal following administration of a satisfactory amount of folic acid.

Despite the fact that there are no published reports confirming this work,[7] the findings are so striking that I have no hesitancy in making the statement that folic acid (synthetic Lactobacillus casei factor), a vitamin present in liver, yeast and other food materials, is a potent antianemic factor in certain types of macrocytic anemia in relapse. Folic acid performs a specific function in the maturation of the various cells of the bone marrow and has other obvious profound effects on our bodies.

---

[7] Since this writing, personal communications from C. A. Doan and his associates at Columbus, Ohio, and from C. V. Moore and his associates at St. Louis have been received confirming the antianemic action of folic acid.

Intracranial Pressure.—Sudden intense increased intracranial pressure is brought about by deformation of the skull and acceleration of the head. The well known observation that the cranial cavity is spheroid in shape and that any change in its diameters would tend to decrease its volume capacity indicates one cause for increased intracranial pressure in closed wounds of the head. Another is the sudden setting of the head to motion or acceleration. Severe circumscribed depressed fractures may be associated with increased pressure due to the plunger effect of the depression. More extensive depressions may be associated with increased intracranial pressure, depending on their extent and the time period of their production. Cannon and Kocher felt that there was an increase in intracranial pressure at the time of the blow, and Scott demonstrated this change by the use of the Hamilton manometer. The increase in pressure is of such short duration that ordinary means of recording do not demonstrate it.—Gurdjian, E. S., and Webster, J. E.: Experimental and Clinical Studies on the Mechanism of Head Injury, in Trauma of the Central Nervous System, Baltimore, Williams & Wilkins Company, 1945.

SEVERE POSTOPERATIVE HYPOGLYCEMIA

DAVID W. BLOOD, M.D.
New York

The clinical state associated with hypoglycemia is assuming an increasing importance in the differential diagnosis of atypical nervous system reactions. Since the first description of this condition by Harris[1] in 1924 there has developed a large body of literature pertaining in particular to etiologic mechanisms. Many organs of the body, including the liver, pancreas, adrenal, thyroid and pituitary, have seemed to play a role in various instances, but there have been certain other cases for which no acceptable explanation was apparent.

In the numerous reports of these cases of unexplained spontaneous hypoglycemia, little has been written concerning a decrease in blood sugar in previously asymptomatic individuals following a surgical procedure. Coma following an operation, while relatively rare, is a disturbing complication and the cases reported here illustrate another etiologic possibility which must be considered in the presence of this perplexing problem. In the past two years we have had 3 examples of such profound hypoglycemia following surgical procedures:

CASE 1.—Mrs. E. K., aged 76, white, a housewife, admitted to the fracture service of the Presbyterian Hospital for the second time on Sept. 16, 1943, complained of pain in the left hip of four months' duration. Her first admission had been in September 1941 for a fracture of the neck of the left femur. This had been successfully treated by fixation with a Smith-Petersen nail. She had been well since that time except for considerable fatigue, which was occasionally accompanied by substernal pressure and moderate dyspnea. Her general health had always been good and she had had no weight loss, headaches, vertigo or fever. She had never had ankle edema, orthopnea, cough or cyanosis. Her son stated that on several occasions she had complained of mild vertigo in the midafternoon or at bedtime. At the age of 22 she had a uterine fibroid removed and had had typhoid at 12. The family history was noncontributory. The patient was thin and nervous. The only positive findings on physical examination were slight narrowing of the arterioles of the fundi, a lower abdominal scar and a blood pressure of 160/88. Reflexes and neurologic signs were not abnormal.

Laboratory examination revealed hemoglobin 14.5 Gm., red blood cells 4.7 million and white blood cells 8,250 with 48 per cent polymorphonuclears, 45 per cent lymphocytes, 4 per cent monocytes and 3 per cent eosinophils. The urine was normal. An electrocardiogram showed low voltage of T_1 and isoelectric T_4F which suggested some myocardial damage. X-ray examination of the heart showed no evidence of cardiac enlargement.

On the fifth hospital day the Smith-Petersen nail was removed from the left hip. The preoperative medication was morphine sulfate 0.006 Gm. and scopolamine 0.0003 Gm. Anesthesia was local with procaine hydrochloride and the total duration of the procedure was forty minutes. No epinephrine or nitrous oxide was used. The patient withstood the procedure well and was returned to her room in good condition. Five hours later she began to feel very weak and thirsty and perspired freely. The lungs were clear and the blood pressure was 160/78. The pulse was irregular. Within two hours she was stuporous and perspiring profoundly but could be aroused. Blood pressure was 140/40. There was no cyanosis, and the lungs were clear. The speech had become sluggish, and she complained of a sense of pressure in the chest. In view of the past history of substernal oppression a myocardial infarction was suspected, but the picture more closely resembled the hypoglycemic state and therefore the blood sugar was determined, 24 mg. per hundred cubic

---

From the Department of Medicine, Columbia University College of Physicians and Surgeons, and the Presbyterian Hospital in the city of New York.

[1] Harris, S.: Hyperinsulinism and Dysinsulinism, J. A. M. A. **83**: 729-733 (Sept. 6) 1924.

centimeters. Following an infusion of 5 per cent dextrose in saline solution the patient gradually improved, so that within six hours she was well oriented and talkative.

Next day the patient had four tonic-clonic convulsions, relieved immediately by intravenous 50 per cent glucose. Her blood sugar during these episodes was as low as 35 mg. per hundred cubic centimeters. Serum bicarbonate was 20.9 milliequivalents per liter and serum chlorides 107.3 milliequivalents per liter. An electrocardiogram taken this day showed changes which suggested an active process in the myocardium. Because of the persistent hypoglycemia the patient was started on a continuous intravenous drip of saline solution alternating with 10 per cent glucose. During the first postoperative day she received 75 Gm. of glucose. In order to increase this, on the following day a Miller-Abbott tube was introduced, and this, plus the intravenous route, allowed an intake of 1,050 Gm. of carbohydrate. Approximately the same regimen was continued. The fluid intake and output were more than adequate throughout.

During the ensuing days it was found that the patient required from 800 to 1,000 Gm. of glucose daily to remain out of hypoglycemia, but even on this regimen the blood sugar was as low as 39 mg. per hundred cubic centimeters. On the fourth postoperative day it was obvious that the patient was losing ground. Her fasting blood sugar was 40 mg. per hundred cubic centimeters; it was also 40 mg. per hundred cubic centimeters before lunch and rose only to 61 mg. per hundred cubic centimeters following the meal. Serum chlorides were 100 mEq./L., bicarbonate was 20.1 mEq./L., and the "calculated serum sodium" 130 mEq./L. The blood count showed only a mild anemia with no leukocytosis. An electrocardiogram taken that day showed further changes diagnostic of myocardial damage. X-ray examination of the chest showed peribronchial consolidation in the middle zone of the right lung. Her temperature had gone to 102.4 F. immediately after operation and to 103 F. on the second postoperative day, and now on the fourth day it rose suddenly to 103 F. A transfusion was given at this time and seemed to improve the general condition. She had considerable diarrhea, believed to be due to the tube feedings of glucose.

Because of the possibility of a pancreatic adenoma, an emergency exploratory operation was done on the fourth postoperative day. At operation there was a moderate amount of amber colored peritoneal fluid. The peritoneum was not inflamed, but the stomach was distended. The liver was smaller than normal, was dark green and showed numerous areas of fibrosis, especially in the region of the gallbladder. The whole organ was much firmer than usual. The gallbladder was normal. No abnormalities were seen or felt in the pancreas after careful examination. By the time the pancreas was exposed the heart beat had become imperceptible, and in spite of continued artificial respiration the patient died. Permission for autopsy was not granted.

Case 2.—V. U., a white man aged 27, a lawyer, was admitted to the urologic service of the Presbyterian Hospital on May 10, 1944 complaining of intermittent hematuria, left inguinal pain and urinary frequency of six months' duration. His past history and family history were noncontributory. There was no history of tuberculosis, acute rheumatic fever, diabetes or heart disease. Seven years previous to admission he had had an operation for intestinal obstruction, and subsequently an ectopic right kidney was removed following a severe attack of pain during the convalescent period. The appendix had been removed fifteen years previous to the present admission. Following the removal of the right kidney the patient had intermittent painless hematuria until six months before admission, when it became associated with left inguinal pain, frequency of urination and vomiting, which continued to the time of admission. There had been a 5 pound (2.3 Kg.) weight loss in two years. On physical examination the patient appeared well developed and in no acute distress. The temperature was 99.6 F., pulse rate 76, respiratory rate 20 and blood pressure 130/80. There were a McBurney incision and lower right rectus scars. The liver and left kidney were palpable but not tender. There was a well healed scar on the lateral aspect of the left thigh and upper part of the leg. Neurologic examination was negative.

Laboratory examination revealed hemoglobin 16.2 Gm., red blood cells 5.22 million, white blood cells 5,600 with 67 per cent polymorphonuclears, lymphocytes 30 per cent, monocytes 3 per cent. The urine showed a specific gravity of 1.011, alkaline reaction, albumin 2 plus, glucose negative and microscopically 15 to 20 red blood cells and 25 to 35 white blood cells per high power field. The Kline reaction was negative. The sedimentation rate was 3 mm. fall in one hour. Blood urea nitrogen was 9.8 mg. per hundred cubic centimeters. Retrograde pyelography demonstrated the presence of renal calculi in a nonrotated hydronephrotic left kidney and an absent right kidney.

In view of these findings a left pyelolithotomy was done on the fifth hospital day. The preoperative medication was morphine sulfate 0.012 Gm. and scopolamine 0.0004 Gm. The anesthesia was nitrous oxide, oxygen and ether by the closed method. The anesthesia was without incident and the duration of the operation thirty minutes. At operation two large stones composed of calcium and ammonium phosphates were removed from the left kidney pelvis. The blood pressure remained normal throughout the operation, and the condition of the patient was satisfactory at the end of the procedure.

Postoperatively the patient was given only 1,500 cc. of isotonic solution of sodium chloride. Ten hours later he was found to be moderately stuporous and within two hours comatose. The blood pressure was 120/55. Both diabetic coma and uremia were considered. Urinalysis showed a specific gravity of 1.013, albumin 4 plus, glucose negative and microscopically a few pus cells. Four hours later the patient was still comatose, had developed Cheyne-Stokes respiration, was perspiring profusely and had conjugate deviation of the eyes to the right with nystagmus to the right. The pupils were fixed to light. Reflexes were equal and active, and the Chvostek sign was negative. Intravenous calcium gluconate was given with no benefit. Blood sugar taken at the time was 38.5 mg. per hundred cubic centimeters, serum bicarbonate 20.5 mEq./L., urea nitrogen 18.2 mg. per hundred cubic centimeters. Fifty cc. of 50 per cent glucose solution was given intravenously, with gratifying improvement. The patient roused immediately and became oriented. The respirations became normal and the pupils again reacted to light. There were no localizing neurologic signs. A continuous intravenous drip of 10 per cent glucose was started, but the patient continued to have recurrent coma and restlessness. The patient was seen later that day by a neurologist, who believed the condition to be a result of hypoglycemia with possible permanent cerebral damage. A lumbar puncture was done. The fluid was crystal clear at a pressure of 196 mm. with normal manometric studies. It contained 4 cells per cubic millimeter, protein was 43 mg. per hundred cubic centimeters and the Wassermann reaction was negative. On the first postoperative day the temperature began to rise and did so steadily. It was considered that the patient possibly had an atypical pancreatic adenoma, and for this reason exploration was done. At the operation the duodenum was mobilized and after careful investigation no pathologic condition could be found in the pancreas. A biopsy of the liver was done at the time, which showed no abnormalities. The patient's blood sugar two hours after operation was 143 mg. per hundred cubic centimeters, but he remained in coma in spite of intravenous 50 per cent glucose solution. Blood sugars before and seventeen minutes after the administration of epinephrine showed no change at this time. There was a leukocytosis of 21,500, with polymorphonuclears 88 per cent. The serum bicarbonate was 21.9 mEq./L., chlorides 103.8 mEq./L. Two 10 mg. doses of desoxycorticosterone acetate were given with no beneficial results.

The patient continued in coma and on the seventh hospital day the temperature suddenly went to 107 F. and he died. Permission for autopsy was not granted.

Case 3.—E. L., a white man aged 55, a photographer, was admitted to the surgical service of the Presbyterian Hospital on Feb. 20, 1945 complaining of abdominal pain of three days' duration. Family and past history were noncontributory. For several months preceding admission he had felt considerable fatigue, particularly in the afternoon, but this was not related to the intake of food. There was occasional mild vertigo with these episodes but no particular perspiration. The patient had been greatly overworking for several months preceding admission. He was well until three days before admission, at which time he developed nonradiating pain in the lower part of the right upper quadrant just to the right of the umbilicus. This pain came on at night and was intense enough to prevent sleep. Accompanying this was a moderate amount of "heartburn" and considerable anorexia but no nausea. Bowel movements were normal. This pain was very persistent and continued to the day of admission. The day before, following the taking of sodium bicarbonate in warm water, he vomited, with some relief. On physical examination he was alert and cooperative and appeared to be in mild distress. There was considerable tenderness in the right upper quadrant and to a lesser degree over the entire right side of the abdomen. There was also a left indirect inguinal hernia and some tenderness in the right subcostal region. Blood pressure was 140/80.

Laboratory examination revealed white blood cells 14,100 with polymorphonuclears 84 per cent, lymphocytes 9 per cent, monocytes 6 per cent and basophils 1 per cent. The urine showed a specific gravity of 1.027, acid reaction, albumin 1 plus, glucose negative and microscopically 5 to 6 red blood cells and a rare white cell per high power field. The Kline reaction was negative. A flat plate of the abdomen showed no urinary calculi.

The patient was observed for two days in the hospital and the abdomen became definitely more tender over the right upper quadrant, but during the second day this tenderness moved down into the right lower quadrant, especially laterally, and it was considered that the appendix was the most probable source of difficulty. Therefore, on the second hospital day an exploratory celiotomy was done under nitrous oxide, ether and oxygen anesthesia by the closed method. The preoperative medication was morphine sulfate 0.012 Gm. and scopolamine 0.0005 Gm. The duration of the anesthesia was one hour and twenty minutes. The procedure was done through a right lower quadrant intermuscular incision. No pathologic condition was found, but the appendix was removed and on section showed only distal occlusion. The patient had vomited once during the induction state of anesthesia but had been in good condition otherwise. After completion of the operation he suddenly became quite cyanotic. The pulse was 84 and of good quality and the blood pressure, which had been 120/70, went only to 130/70. He responded well to oxygen and was supported by this measure for three hours in the operating room. During this period he responded slightly and it was noticed that the right eye was divergent. The left side of the chest showed relative limitation of movement and therefore bronchoscopy was done while he was still in the operating room and a moderate amount of mucus was removed. Aspiration of gastric contents or a cerebrovascular accident was suggested as a possible complication. During the next twenty-four hours the patient responded to a moderate degree but was very drowsy and difficult to arouse. The following morning a blood sugar test was 42 mg. per hundred cubic centimeters and he was again comatose. He had been moderately alert during the preceding six hours. Blood pressure was 120/80, temperature 102 F., pulse rate 88, respiratory rate 12. All extremities were flaccid and there was a slightly positive Babinski sign on the right. The knee jerks were absent. The pupils were small but reacted to light, and there was a right external strabismus. The left side of the chest was still relatively limited in motion. Nonprotein nitrogen was 43 mg. per hundred cubic centimeters. The x-ray of the chest showed peribronchial pneumonia at the right lung base. For this sulfadiazine was given and a level of 7 to .15 mg. per hundred cubic centimeters maintained. Because of the hypoglycemia the patient was put on a regimen of 5 and 10 per cent glucose intravenously and in spite of this was alternately in and out of hypoglycemic shock. A lumbar puncture was done and yielded crystal clear fluid at an initial pressure of 200 mm. The protein was 31 mg. per hundred cubic centimeters and sugar 56 mg. per hundred cubic centimeters. Alcohol and cholesterin Wassermann antigens were negative. X-ray examination of the skull showed no abnormalities.

The patient was continued on intravenous glucose for the hypoglycemia, and oxygen for the persistent cyanosis and dyspnea. The presence of an expanding intracranial lesion was believed to be improbable. Further chemical studies were done in an effort to find a solution. Serum bicarbonate was 29.7 mEq./L., serum amylase 32 units, inorganic phosphorus 4 mg. per hundred cubic centimeters, alkaline phosphatase 5.3 Bodansky units, urea nitrogen 18 mg. per hundred cubic centimeters, serum bilirubin a very faint trace, cholesterol 150 mg. per hundred cubic centimeters, total serum protein 6.5 per cent, albumin 4 per cent, globulin 2.5 per cent, cephalin flocculation negative. There was no anemia or leukocytosis. The sedimentation rate was 66 mm. in one hour. Venous pressure was 76 mm. of saline solution.

During the postoperative course the patient had many blood sugar determinations. The lowest recorded was 21 mg. per hundred cubic centimeters. During the first three days the patient's state of consciousness was well correlated with the degree of hypoglycemia as controlled by glucose injection. At that time he was placed on a regimen of epinephrine in oil intramuscularly 1 mg. every four hours, and a high protein diet. He was given 100 cc. of amigen and 100 cc. of orange juice by stomach tube on alternate hours. On this intake of 1,000 to 1,200 Gm. of carbohydrate in each twenty-four hours his blood sugar was maintained around 80 mg. per hundred cubic centimeters.

On the fourth postoperative day with no change in regimen the blood sugar went to 314 mg. per hundred cubic centimeters and continued in that range, reaching a high of 482 mg. per hundred cubic centimeters. There was an accompanying glycosuria. The following day the amigen diet was discontinued and, as he was then completely conscious and cooperative, a regular diet started. No insulin was given. By the following morning the blood sugar was 64 mg. per hundred cubic centimeters and the patient was again stuporous. However, this state was transient and his blood sugar soon returned to normal limits and he became asymptomatic. It was thought inadvisable to do a glucose tolerance curve. A cholecystogram done just before discharge revealed a definite gallbladder calculus. He left the hospital on the twenty-second day asymptomatic and on a regular diet without supplemental feedings. A fasting blood sugar done two weeks after discharge was 98 mg. per hundred cubic centimeters, and six weeks later he is apparently normal.

COMMENT

Conn[2] has offered a very complete classification of the etiologic mechanisms productive of hypoglycemia, but none of these cases fit into his schema. There was no evidence of disorder in the adrenals, pituitary, thyroid or ovaries. The pancreas as the primary factor must be considered. In the first 2 cases exploration did not necessarily rule out the pancreatic origin of the low blood sugar. Such factors as extrapancreatic islet cell tumors and diffuse hyperplasia of the pancreas[3] should be mentioned. However, with the sudden onset and the previously negative history their existence seems improbable. Harris[4] has shown that a subacute pancreatitis can produce symptoms of hypoglycemia. With the persistent elevation of the sedimentation rate in the third case plus the history of abdominal pain with no surgical pathologic change to account for it, the possibility of such a lesion must be admitted. The atypical history, normal amylase, severity of the hypoglycemia and again the fact that it came on suddenly following a surgical procedure provide evidence to the contrary.

4. Harris, S.: Hyperinsulinism: Definite Disease Entity; Etiology, Pathology, Symptoms, Diagnosis, Prognosis and Treatment of Spontaneous Insulogenic Hypoglycemia (Hyperinsulinism), J. A. M. A. **101**: 1958-1965 (Dec. 16) 1933.

Serious liver damage is a recognized source of hypoglycemia. In case 1 there was evidence of fairly definite cirrhosis, but the liver was not involved in the other 2 cases. However, it is unusual[5] to find clinical or laboratory evidence of hypoglycemia in any but the most pronounced involvement of the liver parenchyma, and such was not the case in the patients in this series.

Patient 3 was known to have cholelithiasis. Coller and Jackson[6] believe that gallbladder disease and involvement of the biliary tract may cause changes in liver function of sufficient intensity to produce hypoglycemia. Conn[2] reported the occurrence of hypoglycemia in a patient with cholecystitis relieved by cholecystectomy. Although a similar situation cannot be definitely ruled out in our case, it again seems improbable in view of the sudden onset and the absence of evidence of acute gallbladder disease.

The possibility of a primary disturbance in the central nervous system must be mentioned. It is known experimentally[7] that stimulation of the right vagus will produce hypoglycemia, but only of a minor degree. Furthermore, Keller[8] found it necessary to sever free the ventral one third to one half of the thalamus in order to produce a hypoglycemic crisis in the dog. With this information in mind and considering the intensity of the hypoglycemia in these cases, it seems unjustified to assume that such a nervous system lesion is the cause of the hypoglycemic state in our patients.

Quirno and Linzoain[9] in 1943 reported a case of hypoglycemia in a woman following a cesarean section. The authors were of the opinion that possible causes were the known diminution in liver glycogen in pregnant women, plus the increased utilization during labor, and the added factor of an absolute lack of carbohydrate intake for forty-eight hours from the time of the operation to the onset of symptoms. The patient subsequently recovered.

Holman, Wood and Stockton[10] in 1943 reported a case of hypoglycemia of severe degree in which recovery occurred spontaneously following pancreatic exploration with negative findings. No explanation was offered for the phenomenon.

Failing to demonstrate in our patients any of the well recognized mechanisms productive of hypoglycemia, the next step is a search for some common denominator. The surgical procedures were in no way similar nor was the anesthesia; local anesthesia was used in only 1 case. The known common factors were morphine, scopolamine and the general shock of an operation. It is difficult to accept these routine therapies as a significant contribution to the production of hypoglycemia, although it is perhaps more than a coincidence that all three followed immediately on a surgical operation.

While in the present state of our knowledge it is idle to speculate as to the cause of the reactions, it is nevertheless worth while to point out that hypoglycemia should be considered when there are unusual responses during or following an operation. Differentiation from surgical shock might at times be a problem. According to Papper and his associates[11] the characteristic differentiating points are those of severe diaphoresis, an increased pulse pressure and a forceful pulse in hypoglycemic shock as opposed to a decreased pulse pressure and thready pulse in surgical shock. Hypoglycemic shock postoperatively is not a common occurrence, and its consequences if untreated are serious. Since it is easily diagnosed and amenable to therapy in its early stages, its recognition is of prime importance.

SUMMARY

1. Of 3 unusual cases of severe postoperative hypoglycemia 2 ended fatally. The third patient recovered and has remained normal to date.

2. In spite of a consideration of the possible etiologic mechanisms, no explanation of the phenomena seems apparent.

3. Although rare, the hypoglycemic state must be considered and a blood sugar level determined in any abnormal central nervous system response following a surgical procedure, even though it is a minor one.

UNCOMMON CLINICAL MANIFESTATIONS OF VIVAX MALARIA

MAJOR HARRY MOST
and
COLONEL JOSEPH M. HAYMAN Jr.
Medical Corps, Army of the United States

The clinical diagnosis of vivax malaria in this country is often not difficult. The patient, in many instances, can suggest the correct diagnosis at the onset of an attack, and this can easily be confirmed by the demonstration of malarial parasites in one or more examinations of blood smears. There is a history of residence in an endemic area and, except for the first attack, there have been previous similar attacks. The symptoms of a "paroxysm" (acute attack) as a rule are quite characteristic, consisting of chilliness followed by a chill of varying severity and high fever of short duration followed by sweating, headache, backache, generalized aching and malaise, weakness, abdominal pain and tenderness and frequently nausea and vomiting. Vague muscular and joint pains, malaise, headache, backache and slight fever may precede the acute attack by several days.

Without treatment, paroxysms recur daily or every other day for a varying period. In a small number of patients spontaneous recovery takes place after one or more days, while in the majority of untreated patients the disease continues its activity for an extended period. With proper treatment there is prompt control of fever and other symptoms, and usually recovery from the acute attack is complete within a week. Complications or sequelae are rare, but one or more relapses follow in a majority of cases.

In studies comprising large numbers of patients with infections due to Plasmodium vivax several distinctly uncommon clinical manifestations have been encountered. Unless one is familiar with such modes of onset the diagnosis of vivax malaria may not be suspected, correct treatment will be delayed, and in some instances other treatment potentially dangerous to the patient may be instituted. Our purpose in this paper is to present briefly a few of the less common clinical manifestations of malaria due to P. vivax.

A. "DELAYED PRIMARY" ATTACKS SIMULATING FEVERS OF UNKNOWN ORIGIN

Military or civilian personnel who have been on duty in endemic areas and have taken quinacrine regularly and in sufficient amounts for effective suppression will give no history of malaria while overseas. Sooner or later after they have returned to the United States they will discontinue taking suppressive medication. Those who have been infected with P. vivax will exhibit clinical signs and symptoms of active malaria within several weeks or months after stopping quinacrine. The onset of the disease in this group as well as in primary attacks when no antimalarial had been taken frequently does not conform to that usually associated with malaria by the general practitioner. The disease may begin insidiously with malaise and headache. The temperature, which is elevated slightly at the onset, rises gradually or abruptly within a few days to 103 or 104 F. and the pattern of the temperature may be completely irregular or of a septic remittent type. Severe shaking chills, which are so characteristic of relapses, may be absent during the first few days of the delayed primary attack despite high fever. Further, and often confusing to the physician, is the fact that one or two routine smears made early may be negative for malaria parasites. We have seen patients with delayed primary vivax malaria who had negative thick smears (less than 1 parasite in 72 squares, 0.1 cubic millimeter) when examined twice daily for two to five consecutive days despite high fever and daily chills before parasites could be demonstrated. When parasites do appear they may be present in relatively small numbers, in contrast to a relapse, in which the smears are usually positive on the first examination and the parasite count is relatively much higher.

We appreciate the quandary of the physician faced with a patient who has been sick for several days with rising fever, vague complaints and little in the way of physical findings. The white blood cell count is usually low, and if the spleen is palpable one may think of typhoid or some other bacterial blood stream infection. The temptation to prescribe sulfonamides or penicillin is great, especially if the first few blood smears are negative for parasites, and we have seen patients with this type of onset who received large amounts of penicillin without benefit.

We suggest that unexplained fever in the returned serviceman should not be treated until a definite diagnosis has been established unless laboratory facilities are not available. Thick smears should be examined twice daily by a trained technician and continued for at least a week. In the meantime, other diagnostic studies can be carried out without compromising the patient's chances of recovery by waiting or withholding therapy. If malaria parasites are demonstrated, the disease has been correctly documented and this is important as a baseline for future recurrences of a similar nature. It must also be remembered that in a few individuals the delayed primary attack may occur as long as a year after suppressive medication has been discontinued. Nevertheless it is helpful in the management of cases of fever of unknown origin as described to know whether the patient has been in endemic malaria areas, when he stopped suppressive medication and whether he has had similar episodes previously controlled with antimalarial medication.

B. SIMULATED PRIMARY ABDOMINAL CONDITIONS

1. *Acute Episodes.*—Attacks of vivax malaria are frequently accompanied by gastrointestinal symptoms and signs of varying severity. Nausea, vomiting and abdominal pain and tenderness are common, usually follow the paroxysm and are rarely of such intensity as to confuse the diagnosis of malaria.

In a small number of patients, however, the abdominal symptoms and signs may precede the paroxysm by a day or two and be of such severity as to suggest a primary acute abdominal condition, particularly acute appendicitis, intestinal obstruction or acute cholecystitis. Unless one is aware of this possibility, needless surgery may be performed.

At this hospital alone we have seen 3 patients who could easily have undergone laparotomy because of severe abdominal signs and symptoms which preceded an attack of malaria by one or two days. Two of these patients were referred to the hospital for surgery from nearby military establishments with the diagnosis of acute appendicitis. The history was identical in the 2 and consisted of abdominal pain followed by nausea and vomiting and localization of the pain in the lower abdomen. There was diffuse tenderness but no rigidity. In 1 the white blood cell count was normal and in the other it was low. Both patients had a slightly elevated temperature. Malaria parasites (P. vivax) were discovered in the thin smear in 1 case while the differential count was being done, and in the other they were found in the thick drop. One patient had a typical chill and other characteristic symptoms of vivax malaria on the same day of admission and the other had his attack the day after he was admitted. Signs and symptoms related to the abdomen disappeared with specific antimalarial treatment. In contrast to the usual findings in acute appendicitis the abdominal pain in malaria is more diffuse, tenderness is present in both lower quadrants, muscular rigidity is absent and rectal examination is not localizing.

A third patient was under observation for two days because of intractable nausea, vomiting, abdominal pain and suspected intestinal obstruction. There was slight fever, the abdomen was diffusely tender and the white blood cell count was 23,000 per cubic millimeter. On the second day the patient volunteered the fact that he had had two previous episodes of severe abdominal pain and vomiting which were followed in from one to three days by an attack of malaria. Thick smears were examined and found to contain a moderate number of parasites (P. vivax). Treatment with parenteral quinacrine was begun. Fluids were given intravenously and nothing by mouth. Later in the day the patient had a typical paroxysm with a rise in temperature to 104.2 F. Quinacrine therapy was continued by the intramuscular route for the remainder of the day. On the following day vomiting had ceased, the temperature and white blood cell counts were normal and specific medication was continued orally. This patient, who was a member of our detachment, had a similar attack of severe abdominal pain, vomiting, leukocytosis and slight fever approximately four months later. At this time the first observed episode was recalled, smears were examined and found positive, and specific treatment was begun with quinacrine intramuscularly. Recovery was prompt and complete.

Gallbladder disease is most apt to be confusing in those cases in which there is slight enlargement and tenderness of the liver with minimal icterus from previous paroxysms. On the other hand, we have seen a patient whose gallbladder perforated while his right upper quadrant pain, nausea and vomiting were attributed to his malaria.

Apropos of simulated acute abdominal conditions due to malaria, it should be remembered that they occur more frequently and with greater severity in acute falciparum infections. We have seen laparotomy performed for suspected intestinal obstruction, cholecystitis and extrahepatic biliary obstruction in 3 cases. At autopsy in each case the primary cause of death was acute falciparum malaria! In these cases the acute abdominal findings overshadowed the possibility of malaria, but careful histories and repeated careful blood examinations could in all probability have established the correct diagnosis.

In a small number of patients an attack of malaria may be preceded by several days or ushered in with a period of brisk watery diarrhea. If fever and vomiting occur before the chill, one may suspect acute gastroenteritis. The smears are almost always positive and within a short time the typical chill, high fever and other symptoms will suggest the correct diagnosis. In many of these cases the symptoms accompany each relapse and a good history is extremely helpful.

2. *Signs and Symptoms of a Chronic Nature.*—Occasionally protracted low grade malarial activity in some individuals with good immunity may be manifested by slight to moderate anemia, slight icterus and enlargement of the liver and/or spleen. Inadequate treatment of frequently occurring mild attacks may also produce the same findings. Either there is no fever or, if present, it is low grade. Parasites are almost always present in the circulating blood, but their density may be very low. In such a combination of findings one may suspect some intrinsic disease of the liver, gallbladder or biliary system or some hematologic disorder rather than malaria. We have seen several such cases with a red blood count as low as 2.2 million per cubic millimeter and in each instance careful study of blood smears proved the underlying condition to be vivax infection. Specific therapy with antimalarial drugs produces a reticulocyte response, recession of the liver, disappearance of signs and symptoms and recovery from the anemia without iron or other drugs.

One of us (H. M.) has seen a Chinese patient with enlargement of the liver and spleen and reduction in all the formed elements of the blood in whom the diagnosis of Banti's syndrome led to splenectomy. Several weeks after recovery from the operation the patient complained of chills and fever. Examination of blood smears disclosed numerous quartan parasites (Plasmodium malariae) and review of preoperative filed blood smears likewise disclosed very rare parasites. While this condition may not occur often if at all in vivax malaria it is worth noting what the effect of protracted low grade malaria infection may be regardless of the species of parasite.

If the possibility is borne in mind that gastrointestinal symptoms and signs of varying intensity or chronicity may be related to underlying infection with P. vivax in some cases the correct diagnosis may be established and needless surgery avoided. It is not suggested that all acute or chronic gastrointestinal conditions occurring in patients who have had malaria are related to that disease. In fact, we have seen a moderate number of patients with a history of prior malaria suffering currently from chills, fever, abdominal or other signs and symptoms who were treated without benefit with antimalarial drugs on the assumption that the findings were due to malaria. Smears were negative and the white blood cell count elevated, which is exceptional in malaria. The conditions subsequently shown to be incorrectly diagnosed as malaria were, in their order of frequency, acute follicular tonsillitis, cellulitis, thrombophlebitis, pyelitis, pneumonia and cholecystitis.

A careful history particularly of previous similar episodes related to proved attacks of malaria, physical and laboratory examinations including careful search for malaria parasites and evaluation of all the findings possibly in conjunction with a surgeon when indicated should lead to a rational plan of management of the individual case.

C. CENTRAL NERVOUS SYSTEM MANIFESTATIONS

Signs or symptoms referable to the central nervous system in malaria occur most frequently in severe infections with Plasmodium falciparum. It is for this reason that there is a tendency to label all central nervous system manifestations occurring in malaria as "cerebral malaria," with the alarming implications and necessity for vigorous treatment which severe falciparum infections carry. The changes in the brain in falciparum infections consist of occlusion of small vessels with parasitized red cells, parasites, pigment and débris, multiple small discrete or ring shaped hemorrhages and other pathologic alterations. No such changes in the brain in vivax infections have ever been described to our knowledge. Furthermore, falciparum infections, if adequately treated or suppressed with quinacrine, rarely relapse. However, if central nervous system systems and signs occur at the onset of an attack of malaria and there is any question about the history or species of parasite observed or if no history can be obtained, the safest procedure to follow is the institution of vigorous parenteral antimalarial therapy until it can be decided whether or not the infection is due to P. falciparum.

We have seen definite and severe symptoms and signs referable to the central nervous system at the onset of attacks of vivax malaria which are worthy of note. Severe headache is common but is not alarming, and symptomatic treatment suffices. Delirium is seen in some patients and is probably an expression of hyperpyrexia in individuals sensitive to high fever. Antipyretics, sponging, parenteral fluids and ice caps to the head usually are effective in controlling this symptom. Acute psychoses may occur during treatment and represent a rare manifestation of quinacrine toxicity unrelated to malaria itself. Severe stiffness of the neck preceding or accompanied by fever and a chill at the onset of an acute attack of vivax malaria may be suggestive of meningitis which must be excluded. The spinal fluid is normal, the white blood cell count tends to be low and the blood smears contain parasites (P. vivax).

Convulsions at the onset of an attack of vivax malaria may be alarming but fortunately occur rarely. We have seen only 3 examples of convulsions in proved cases of vivax malaria in the course of treating several thousand attacks. Brief reference will be made to these cases:

Case 1.—A man seen shortly after a generalized convulsion was perfectly oriented and stated that he had had convulsions during several previous severe attacks of malaria. These were documented in his medical record, and his transfer diagnosis was "recurrent cerebral malaria." No record of the species of parasite for these previous attacks was available. On the day of the current convulsion the patient had a severe paroxysm. Numerous asexual forms of P. vivax were present in the blood smears. The temperature rose quickly to 104 F., but the patient was fairly comfortable. However, within another half hour the temperature had risen to 105.8 F., shortly after which he had the convulsion. Salt and glucose were administered intravenously immediately afterward as well as 1 Gm. of acetylsalicylic acid by mouth. The patient was sponged with cold water and the naked body cooled with two electric fans. The temperature fell quickly and no further difficulty was experienced. In an attempt to prevent a paroxysm the following day, 1 Gm. of quinacrine was given intramuscularly in divided doses on the first day. There was no subsequent fever and the patient received 1.8 Gm. of quinacrine by mouth during the next six days, after which he continued to receive 0.1 Gm. daily for five months. The spinal fluid, neurologic examination, x-rays of the skull and electroencephalogram were normal. On questioning the patient we learned that he had had convulsions during childhood with measles and during early boyhood with scarlet fever and not again until he had his first attack of malaria many years later. In our opinion, convulsions during an attack of vivax malaria in this patient represent a central nervous system reaction to hyperpyrexia.

CASE 2.—This man likewise was returned from overseas with a diagnosis of "cerebral malaria" because of a severe convulsion during an attack of malaria. The species of parasite had not been identified. While under observation in a malaria study group he complained of severe headache and "spasm" of the right hand. X-rays of the skull, neurologic examination and the spinal fluid at an overseas hospital were normal. The patient stated that he had sustained a severe head injury followed by a short period of unconsciousness and subsequently developed constant headache, which he attributed to the head injury. Shortly after arrival in this country and while in the hospital for study he had a severe epileptiform convulsion starting on the right side and quickly becoming generalized. The patient shrieked at the onset, bit his tongue and was incontinent of urine. The convulsion subsided and the patient remained drowsy for about ten minutes, after which he was confused for another twenty minutes. In the meantime, blood smears were examined and reported as containing numerous malaria parasites (P. vivax). The rectal temperature was 102.8 F. Antimalarial and anticonvulsant drugs (diphenylhydantoin [dilantin] sodium and phenobarbital) were administered simultaneously by mouth. On the second day the patient was afebrile and complained only of a severe headache. There was amnesia for the details of the recent convulsion and slight weakness of the right hand; otherwise complete neurologic examination was negative. The spinal fluid was normal in all respects. At the end of a week antimalarial drugs were discontinued. In the meantime it was learned from another patient that the boy who had the convulsion had been observed in the midst of several convulsions outside the hospital. When we confronted our patient with this information he admitted having had convulsions but said that he was reluctant to report them for fear of being branded epileptic or submitted to cranial surgery. Electroencephalograms showed a localized area of abnormal excitability, but air visualization of the ventricular system was normal. The neurologist and neurosurgeon did not believe that surgery was indicated and classified the disease as a post-traumatic convulsive disorder ("postconcussive encephalopathy with focal area of degeneration, left cerebrum, central area"), recommending that anticonvulsant drugs be continued indefinitely. Two months later the patient, while still on anticonvulsant drugs, experienced a severe attack of malaria with a hard chill and high fever without developing any signs or symptoms related to the brain other than severe headache. We believe there is good evidence in this case that the convulsions which occurred during acute attacks of vivax malaria were due to underlying disease of the brain and that the fever or some other factor in the malaria attack acted as a trigger to set off the seizure. The patient was then kept on quinacrine suppression and anticonvulsant drugs without subsequent malaria or convulsive seizures.

CASE 3.—A white man aged 24 was returned from the Southwest Pacific area with a transfer diagnosis of "psychosis, unclassified, severe, manifested by agitation, blocking of thought and auditory hallucinations." His malaria history overseas disclosed that he had four attacks of malaria while in New Guinea and that during the last two he had convulsions and subsequently developed behavior changes for which he was returned to the United States. The only features in the past history which are relevant are the facts that he had criminal tendencies, spending short periods of time in a state reformatory or under parole, that he was poorly adjusted socially and that infrequently he had vague "spells" which could possibly have been "petit mal." It also seems probable from a review of his overseas record that his first serious attack of malaria during which he was in coma and had convulsions was due to infection with P. falciparum. Examination in this country failed to show evidence of any psychosis. Neurologic examination was negative. The spinal fluid on several occasions showed slight elevation in protein. Two electroencephalograms were considered abnormal and were "suggestive of epilepsy or some related disorder." While under observation at another hospital in this country he had one episode related to a vivax relapse during which there were symptoms and signs referable to the nervous system. These consisted of sudden onset of stuporousness and signs of minimal bulbar palsy characterized by nasal regurgitation, drooling and continual clearing of the throat because of impaired pharyngeal reflex. A prior attack of supposed falciparum malaria treated early at the same hospital was not accompanied by signs or symptoms related to the nervous system.

While the patient was under observation at this hospital smears were examined repeatedly and no suppressive medication was given. On Aug. 27, 1945 the patient had a positive smear for P. vivax but had no fever or symptoms. The following day, while lying on his bed trying to have a nap, he had a generalized convulsion. He was seen at once and found unconscious, frothing at the mouth and breathing rapidly for a short time followed by a longer period of apnea. The head was retracted to the left; otherwise the neurologic examination was negative. The rectal temperature was 102.2 F. Following recovery from the convulsion, 0.8 Gm. of quinacrine was given intramuscularly in divided doses and glucose in saline solution by vein. The patient remained confused the greater part of the day, but on the following day he had completely recovered except for not remembering the details of the previous day's attack. A total of 2.8 Gm. of quinacrine was given to terminate the recent vivax relapse.

It is difficult to correlate the patient's central nervous system symptoms solely on the basis of vivax malaria. It seems to us that he may well have had changes in the brain in a general way related to convulsive disorders (epilepsy) prior to his first attack of malaria. Secondly, that the initial attack of severe falciparum malaria overseas either aggravated the underlying condition or in itself induced some permanent changes in the brain. Subsequently vivax relapses resulted in the central nervous system signs and symptoms described, which were due to underlying disease of the brain caused or aggravated by prior falciparum malaria with cerebral localization.

The immediate diagnosis in patients with central nervous system signs and symptoms related to an attack of malaria may be difficult. We believe that central nervous system findings in the presence of a late relapse of malaria are probably associated with vivax infection but that the nervous system manifestations are due to underlying disease of the brain such as may be found in epilepsy, following head injury or in rare cases following prior severe falciparum infections with cerebral localization. Regardless of the species of parasite responsible for the current attack, the management is the same; namely, prompt and vigorous antimalarial therapy parenterally. However, the subsequent treatment of these cases poses a more serious problem. Should one continue suppressive medication indefinitely? Careful studies should be instituted to determine whether there is an underlying pathologic condition in the brain. Anticonvulsant drugs should be continued in those individuals who suffer from convulsive disorders until the malaria infection has run its whole course or has otherwise been eradicated by treatment.

D. ALLERGIC MANIFESTATIONS

Writers from the tropics have in the past referred to "malaria sensitization and malaria asthma." We have not seen asthma which could definitely be attributed to malaria. But we have seen 12 patients with urticaria of varying severity which preceded or accompanied an acute attack of vivax malaria, and these are worthy of note in a general way. The first patient reported to his ward officer because of severe generalized urticaria. The latter prescribed symptomatic treatment and arranged for an allergy consultation. When the allergist phoned on the following day to inquire where the patient was, it was learned that he was in bed with an acute attack of vivax malaria. No serious thought was given to a relation of these events. However, soon afterward another patient was seen with urticaria and on the basis of the first case smears were done and found positive for P. vivax. No treatment was given and later in the day the patient had a paroxysm. Subsequently 10 additional patients were observed who had urticaria for one or two days prior to an attack of malaria or on the day of the attack before drugs were given. In some patients the urticaria was very severe, involving the eyes and face, and in 1 patient probably the larynx was involved. These patients had no other allergic history, and a few who were carefully skin tested were found negative to dusts, pollens, common foods or other antigens.

We presume that these patients have been sensitized by the plasmodia or their products and that, when the former are present in sufficient number to exceed the amount of antibody present, urticaria or some other allergic manifestation follows. The fact that urticaria may precede attacks of vivax malaria is useful, and if blood smears are examined the diagnosis can be made early and time consuming allergy studies dispensed with.

E. MISCELLANEOUS

1. *Respiratory Symptoms.*—Upper respiratory symptoms, especially during winter months, are common in vivax malaria. Likewise, chest pain and rales are not uncommon during an attack. These findings in a patient with a chill and a high fever may suggest pneumonia. The chest x-ray is negative and smears will contain parasites, establishing the diagnosis of vivax malaria. These two diseases are not often confused, but we have seen treatment of pneumonia delayed because it was assumed that the patient had malaria, and conversely we have seen suspected pneumonia treated without effect because the patient actually had malaria. In malaria the elevation of temperature is not sustained beyond a few hours after the chill, and the accompanying symptoms, negative x-ray and positive blood smear for parasites should make the diagnosis simple if both diseases are considered.

We have seen 1 patient with sharp chest pain during an attack of vivax malaria which was due to a spontaneous pneumothorax produced during the chill. This is a very unusual occurrence.

2. *Rupture of the Spleen.*—This serious complication is a very rare occurrence during an attack of malaria and is mentioned only in passing. The symptoms and signs are so dramatic and the abdominal findings such that the diagnosis is usually made. Immediate surgery is indicated, following which the attack of malaria can be controlled with parenteral medication.

3. *Chills and Fever After Injuries or Operations.*—It is well known that trauma, general anesthesia or surgery may induce a relapse of vivax malaria. However, this may occur years after cessation of all malaria activity and the disease forgotten. If this is borne in mind and blood smears are examined for malaria parasites, needless worry about postoperative infection or embolization can be avoided.

4. *Chills and Fever or Jaundice After Transfusions.*—Patients who are receiving repeated transfusions of fresh whole blood for an acute or chronic disease may develop jaundice, anemia or chills and fever. This may be due to activity from transfused vivax parasites rather than infectious hepatitis or hemolytic, Rh or pyrogenic reactions. The latter certainly are more common than transfusion malaria, but this possibility must not be overlooked and smears should be examined for parasites.

COMMENT AND CONCLUSIONS

We have described our experience with the relatively uncommon, though not rare, clinical manifestations of vivax malaria with the thought that appreciation of these findings may lead to a more rational approach in the management of acute or chronic problems in the patient who has had or may have vivax malaria.

1. Fevers of unknown origin in the returned serviceman who has not had malaria before because of effective suppression which has now been discontinued for some time may be due to the onset of the first or "delayed primary" attack of malaria. There may be gradually rising fever or high fever with or without chills for several days, during which time smears may be negative. Patience and carefully studied smears made repeatedly will be rewarded in many cases by a diagnosis of vivax malaria. Useless treatment with penicillin or sulfonamides will be avoided and the disease accurately documented for future reference. Therapeutic trials with antimalarial drugs are not advised if laboratory facilities are available.

2. Acute or chronic symptoms or signs suggesting a primary disease related to the abdominal contents may be present prior to or at the onset of an acute attack of vivax malaria or may be the result of a continuing low grade vivax infection. Before surgery is performed, blood smears should be examined carefully to exclude the possibility of active vivax malaria. A history of similar episodes related to proved attacks of malaria is extremely helpful. The most common findings which may be confusing are severe nausea, vomiting, abdominal pain and tenderness, diarrhea, fever, slight jaundice and anemia, and enlargement of the liver and spleen. The white blood cell count is rarely elevated, smears usually contain parasites (P. vivax). Initial treatment when the correct diagnosis has been made consists in giving antimalarial drugs parenterally when severe vomiting exists and the administration of fluids containing salt and glucose intravenously. Subsequent treatment can be given by mouth until the required total amount of drug has been given.

3. Convulsions may occur with attacks of vivax malaria. These may occur as a reaction to hyperpyrexia or in patients with underlying brain disease. Preexisting epilepsy, head injury and falciparum malaria must be excluded. Treatment of the convulsion is symptomatic, and the current attack of malaria is terminated by vigorous dosage of antimalarial drugs parenterally until fever and parasitemia have been controlled. Attempts should be made in exact species identification of the parasite. Acute psychoses occur rarely and are an expression of quinacrine toxicity. Meningitis may be simulated by a stiff neck and fever, but a normal spinal fluid, low or normal white count, the typical paroxysm and positive blood smear for malaria parasites establish the correct diagnosis.

4. Urticaria or severe angioneurotic edema may precede or accompany acute attacks of vivax malaria. A history of such correlated episodes and examination of blood smears will dispense with time consuming allergy studies in these cases.

5. Chest pain, rales, fever and chill occurring with an acute attack of vivax malaria in the winter months may be confused with pneumonia. History, white count, malaria smears and chest x-ray are helpful in differentiation.

6. Miscellaneous manifestations of vivax infection, as rupture of the spleen, pneumothorax following the paroxysm and corneal herpes, are rare and are mentioned in passing. Chills and fever following trauma or surgery may be due to a vivax relapse long after the disease has ceased to be active. Consideration of this occurrence will dispel worry over postoperative infection or embolization. Chills and fever or jaundice in patients who are receiving transfusions repeatedly may be due to transfused vivax parasites and may simulate hemolytic, Rh and pyrogenic reactions or infectious hepatitis.

7. Not all acute or chronic conditions or chills and fever which occur in patients who have had or may have vivax malaria are due to the latter. Such an assumption will lead to failure or delay in recognition and proper treatment of such common conditions as acute follicular tonsillitis, thrombophlebitis, cholecystitis, pyelitis or pneumonia.

8. Acute manifestations of vivax infection can be controlled by the administration of 2.8 Gm. of quinacrine during seven days. Of this total, 1 Gm. is given on the first day in divided doses either by mouth or intramuscularly if severe vomiting or central nervous system symptoms preclude oral medication. Intravenous salt and glucose are helpful in controlling fluid and salt loss and symptoms in vomiting and hyperpyrexia. Antipyretics, intravenous fluids and artificial cooling of the body are useful in reducing abnormally high fever during an attack.

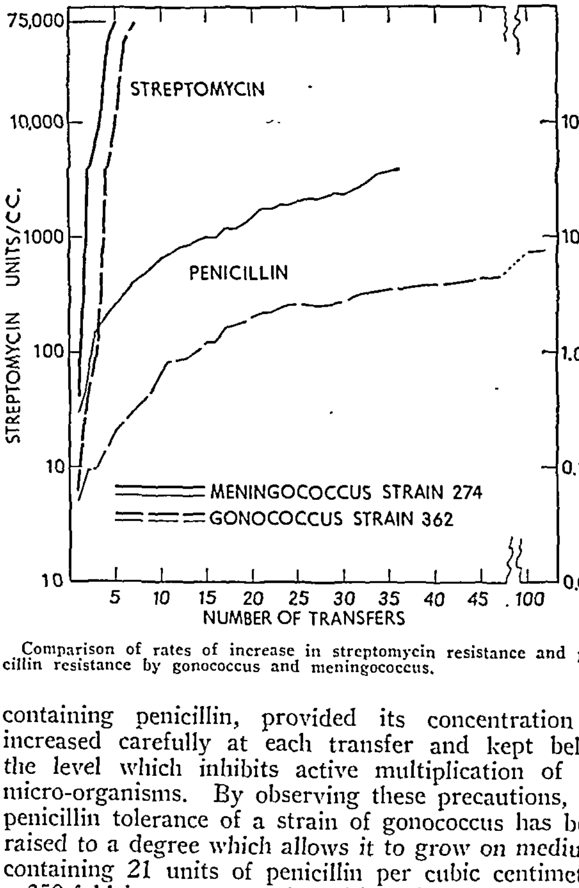
Psychiatric Problems in the Air Forces.—The relation of air sickness to anxiety is interesting in that those who suffer from this malady usually have a good deal of conscious or unconscious anxiety about riding in an airplane. Provided no disease has developed in the internal ear, air sickness in flying personnel not previously afflicted is usually psychogenic and represents an unusual conversion symptom. Yet in civilian life patients during psychoanalytic treatments experience sensations similar to air sickness as symptoms of overwhelming anxiety liberated by the psychic probing.—Grinker, Roy R., and Spiegel, John P.: War Neuroses, Philadelphia, Blakiston Company, 1945.

STREPTOMYCIN RESISTANCE OF GONOCOCCI AND MENINGOCOCCI

C. PHILLIP MILLER, M.D., and MARJORIE BOHNHOFF, B.S.
Chicago

Drug resistance or "fastness," that is the acquisition by micro-organisms of tolerance for chemotherapeutic agents, has long engaged the attention of bacteriologists and parasitologists[1] and has recently become a matter of concern among clinicians and epidemiologists. Resistant strains of micro-organisms usually susceptible to the sulfonamides have been recognized for some time, and penicillin resistant strains are now beginning to appear in clinic and laboratory. The apprehension which might have been caused by the latter is currently being allayed by the introduction of streptomycin.

Experiments which we[2] have recently completed have demonstrated that meningococci and gonococci acquire resistance to penicillin during cultivation on mediums containing penicillin, provided its concentration is increased carefully at each transfer and kept below the level which inhibits active multiplication of the micro-organisms. By observing these precautions, the penicillin tolerance of a strain of gonococcus has been raised to a degree which allows it to grow on mediums containing 21 units of penicillin per cubic centimeter, a 350-fold increase over the initial tolerated concentration. In similar fashion a strain of meningococcus has acquired tolerance for 41 units per cubic centimeter, or 136 times the concentration of penicillin which originally permitted growth. These rates of increase are shown graphically in the accompanying chart.



Comparison of rates of increase in streptomycin resistance and penicillin resistance by gonococcus and meningococcus.

Moreover, the virulence of these penicillin resistant meningococci was retained during a large part of the rise, up to a level of 18 units per cubic centimeter.

From the Department of Medicine and the A. B. Kuppenheimer Foundation of the University of Chicago.

[1] For an early discussion of acquired resistance see Dale, H. H.: Chemotherapy, Physiol. Rev. **3**: 359, 1923.

[2] Miller, C. P., and Bohnhoff, Marjorie: Studies on the Action of Penicillin: IV. The Development of Penicillin Resistance by Gonococcus, Proc. Soc. Exper. Biol. & Med. **60**: 354, 1945; V. The Virulence of Penicillin Resistant Strains of Meningococcus, ibid. **60**: 356, 1945.

Meningococcic infections experimentally produced in mice with these resistant strains required very large doses of penicillin for their control.

The susceptibility of these penicillin resistant strains to streptomycin and the possibility of the development of streptomycin resistance by freshly isolated strains of meningococci and gonococci prompted the investigation here reported.

EXPERIMENTAL

Susceptibility of Gonococci and Meningococci to Streptomycin.—The initial susceptibility of six strains of gonococcus and ninety-six strains of meningococcus were tested for their streptomycin tolerance by inoculating each strain onto a series of blood agar [3] plates containing graded concentrations of streptomycin.[4] The highest concentration on which any colonies developed in forty-eight hours was considered the limit of tolerance for that strain.

Table 1.—*Streptomycin Treatment of Mice Infected with Streptomycin Resistant Meningococci*

In Vitro: Resistance of Meningococci for Streptomycin, Units per Cc.	Number of Mice	Total Dose of Streptomycin * Administered, Units	Results
40	12	50	All died
	18	70	All but 2 survived
	26	100	All survived
10,000	8	9,000†	All died
	8	10,000	All died
	8	15,000†	All died
75,000	8	9,000†	All died
	8	10,000	All died
	8	15,000†	All died

* Given in two subcutaneous injections three and six hours after inoculation; those marked + received three injections two, four and six hours after inoculation.

Table 2.—*Penicillin Treatment of Mice Infected with Streptomycin Resistant Meningococci*

In Vitro: Resistance of Meningococci for Streptomycin, Units per Cc.	Number of Mice	Total Dose of Penicillin * Administered, Units	Results
40	10	10	All but 2 died
	16	20	11 survived
	28	40	All survived
10,000	8	20	4 survived
	8	60	6 survived
75,000	16	20	12 survived
	8	60	All survived
	8	80	All survived

* Given in two subcutaneous injections three and six hours after inoculation.

For the six strains of gonococcus, the streptomycin tolerance varied from 8 to 40 units per cubic centimeter. For the ninety-six strains of meningococcus, it varied from 1 to 40 units per cubic centimeter.[5] All of the strains tested could therefore be classified as susceptible to streptomycin in their original state.

Method of Developing Streptomycin Resistance.—The micro-organisms were grown on freshly prepared blood agar plates containing known concentrations of streptomycin. Each transfer was made onto several plates containing different concentrations of streptomycin to insure abundant growth on at least one. Inoculated plates were placed in a metal box containing a lighted candle and incubated for twenty-four hours, after which they were examined and described. Transfer to the next set of plates was made from the medium which contained the highest concentration of streptomycin permitting growth. Plates which showed no growth at the end of twenty-four hours were returned to the incubator and examined again the following day.

The first few trials showed that both gonococci and meningococci acquire resistance to streptomycin much more rapidly than they do to penicillin.

The rates of increase for a strain of each are presented graphically in the chart, which plots the highest concentration of streptomycin permitting growth in each successive subculture.

All of four strains of gonococcus and nine of meningococcus acquired streptomycin resistance at approximately the same rate; i. e., four to six daily transfers sufficed to raise their resistance to a level which enabled them to grow on mediums containing 75,000 units of streptomycin per cubic centimeter, the highest concentration which was practicable with the supply available.

In contrast with the very rapid rise in streptomycin resistance, penicillin resistance was developed by the same strains at a much slower rate, as shown in the chart.

MORPHOLOGIC APPEARANCE OF STREPTOMYCIN RESISTANT STRAINS

The macroscopic appearance and physical characteristics of colonies as well as the morphology of the individual cells of streptomycin resistant gonococci and meningococci showed none of the changes observed in penicillin resistant strains.

DURATION OF STREPTOMYCIN RESISTANCE

It is too soon to make any statement about the permanence of streptomycin resistance. At present we can only state that it has persisted for three and one-half months.

EFFECT OF STREPTOMYCIN RESISTANCE ON THE VIRULENCE OF MENINGOCOCCI

All of the animal experiments in this study were made with meningococci because they lent themselves more easily to the purpose.

Method of Determining Virulence.—Virulence of meningococci was determined by infecting mice with varying numbers of meningococci suspended in mucin, according to the method of Miller and Castles.[6] By this means less than 10 meningococci of maximal virulence are required to initiate a lethal infection.

The virulence of each strain was determined before and several times during the course of its development of streptomycin resistance. In no instance was there any loss of virulence, and one strain actually increased in virulence to an appreciable degree as it became streptomycin fast.

Determination of the Therapeutic Action of Streptomycin on Experimental Meningococcic Infection.—Mice were infected with standard inoculums of approximately 100,000 minimum lethal doses by the intraperitoneal inoculation of meningococci suspended in mucin and were treated by subcutaneous injection of 0.5 cc. of streptomycin in saline solution three and six hours or two, four and six hours after inoculation. A representative number of the mice dying in each experiment were examined post mortem. Cultures were made of the heart's blood to be sure that death was due to meningococcic sepsis. As will be seen in table 1, infections initiated with 100,000 minimum lethal doses of meningococcus normally susceptible to streptomycin were regularly brought under control by two subcutaneous injections of 50 units of streptomycin, a total of 100 units.

---

[3] The basic ingredient of the agar was a tryptic digest of casein to which 0.065 per cent of cystine was added. Directions for its preparation are given in Miller, Moeller and Bohnhoff (A Method for Production of a Localized Gonococcal Infection in the Rabbit's Eye, Proc. Soc. Exper. Biol. & Med. 58:143, 1945). One-tenth volume of rabbit blood and the appropriate quantity of streptomycin were added at the time the plates were poured and thoroughly mixed before hardening.

[4] Dr. J. M. Carlisle of Merck and Company, Inc., Rahway, N. J., supplied the streptomycin used in these experiments.

[5] It should be remembered that streptomycin units and penicillin units bear no direct relation to each other.

[6] Miller, C. P., and Castles, Ruth: Experimental Meningococcal Infection in the Mouse, J. Infect. Dis. 58:263, 1936.

After the strain had acquired streptomycin resistance in vitro, mice were infected with similar inoculums and treated with streptomycin in the same way. All of these animals succumbed to meningococcic sepsis (proved by cultures of heart's blood) in spite of treatment with streptomycin in doses up to a total of 15,000 units, the largest amount which could be administered without serious symptoms of drug toxicity.

The inability of streptomycin to control infection with streptomycin resistant meningococci was even more strikingly illustrated by the following experiment: Mice were infected with small numbers of streptomycin resistant meningococci (10 to 100 or approximately 10 minimal lethal doses). They were then treated with 15,000 units of streptomycin in three doses. One half of them died, and cultures of heart's blood of all mice examined post mortem were positive for meningococci. This finding confirmed the conclusion drawn from the preceding experiments that meningococci which had acquired streptomycin resistance in vitro were able to produce a fatal sepsis in animals despite treatment by relatively enormous doses of streptomycin.

PENICILLIN TREATMENT OF INFECTIONS WITH STREPTOMYCIN RESISTANT MENINGOCOCCI

The susceptibility of streptomycin resistant gonococci and meningococci to penicillin in vitro suggested the determination of their susceptibility in vivo. Meningococcus was chosen for the experiments because it was better suited to the purpose. Three subcultures of the strain already described were used: one before it had developed any resistance to streptomycin above its initial level of 40 units, and one each after it had acquired resistance to 10,000 and 75,000 units of streptomycin, respectively. Each subculture was used to infect a group of mice, which were then treated with graded doses of penicillin. As will be seen in table 2, very little more penicillin was needed to cure all of the infections in the second and third groups than was required for those in the first group.

When these results are compared with those in table 1, it is obvious that infections with streptomycin fast meningococci which resist treatment with maximum doses of streptomycin yield to small doses of penicillin. In other words, streptomycin resistant meningococci are about as susceptible to penicillin in vivo as they are in vitro.

STREPTOMYCIN SUSCEPTIBILITY OF PENICILLIN RESISTANT GONOCOCCI AND MENINGOCOCCI IN VITRO

Strains of gonococci and meningococci were tested for their streptomycin tolerance in vitro before and after they had become resistant to high concentrations of penicillin. All were found to be at least as susceptible to streptomycin, and one strain of gonococcus became somewhat more susceptible to streptomycin after it had acquired resistance to penicillin than it had been originally.[7]

STREPTOMYCIN TREATMENT OF PENICILLIN RESISTANT INFECTIONS

TABLE 3.—*Comparison of Penicillin and Streptomycin Treatment of Mice Infected with Penicillin Resistant Meningococci*

In Vitro: Resistance of Meningococci for Penicillin, Units per Cc.	Mice Treated with Penicillin			Mice Treated with Streptomycin		
	Number of Mice	Total Dose Administered,* Units	Result	Number of Mice	Total Dose Administered,* Units	Result
0.3	10	10	All but 2 died	12	50	All died
	16	20	11 survived	18	70	All but 2 survived

	8	500	1 died	12	100	All but 1 survived
	16	600	All survived	6	150	All survived

* Given in two subcutaneous injections three and six hours after inoculation.

Mice were infected with meningococci which had been rendered resistant to 10 and 14 units of penicillin per cubic centimeter, and some were treated with penicillin and some with streptomycin. For comparison mice were also infected with cultures of the same strain before it had become penicillin resistant. As will be seen in table 3, very large doses of penicillin were required to cure these infections, showing that the micro-organisms were highly resistant to the action of the drug in vivo as well as in vitro. Nevertheless, these penicillin resistant infections responded favorably to practically the same doses of streptomycin as did infections with nonresistant meningococci.

COMMENT

The initial tolerance of a number of strains of gonococcus and meningococcus for streptomycin was found to vary within very narrow limits, indicating that none of these strains was naturally resistant to the drug. The strains of gonococcus were mostly freshly isolated strains. Those of meningococcus (ninety-six in all) included some recently isolated, many stored in the frozen state since isolation and a few kept under cultivation for months on artificial mediums.

Repeated subcultivation on streptomycin agar induced streptomycin resistance of both gonococci and meningococci at a very rapid rate, so rapid, in fact, that all of the strains subjected to this treatment required only four to six daily transfers to mediums containing increasing concentrations of the drug to permit them to grow abundantly on mediums containing 75,000 units of streptomycin per cubic centimeter, the maximum concentration which could conveniently be employed with the supply at our disposal. This technical limitation prevented the determination of the ultimate limits of streptomycin resistance, a point of considerable importance because it would answer the engaging question whether or not micro-organisms can become completely and absolutely streptomycin fast.

---

[7] Unpublished experiments.

The rate of enhancement of streptomycin resistance becomes even more remarkable when it is compared with that of penicillin resistance on the same strains of gonococci and meningococci by the same methods. The latter proceeded at a much slower pace and never reached levels suggesting the possibility of absolute fastness.

In vitro resistance to streptomycin was confirmed by in vivo experiments which showed that infections with streptomycin resistant strains of meningococci could not be controlled by the largest doses of streptomycin tolerated by the animals, doses which would be equivalent on a weight for weight basis to about 55,000,000 units for a 70 kilogram man.

These streptomycin resistant meningococci were quite susceptible to penicillin in vitro, and infections produced with them were controlled by doses of penicillin equal to or only slightly greater than those required by nonresistant meningococci.

Conversely, penicillin resistant meningococci were normally suceptible to streptomycin on artificial mediums and in the infected animal.

In other words, meningococci resistant to either drug were found to be susceptible to the other in vitro and in vivo. The same correlation was observed in vitro with gonococci.

These observations suggest that streptomycin and penicillin act on these micro-organisms in quite different ways. This conclusion is supported by three other differences in the behavior of gonococci and meningococci toward streptomycin and penicillin: (*a*) the more rapid acquisition of streptomycin resistance, (*b*) the absence in streptomycin resistant gonococci and meningococci of the gross physical change and abnormal microscopic appearance of penicillin resistant micro-organisms and (*c*) the retention or even enhancement of virulence of meningococci after acquiring streptomycin resistance, whereas the development of penicillin resistance tends to lower their virulence somewhat.

It should be pointed out that the observations here described have been made on micro-organisms which have been rendered drug resistant by artificial means and that these findings must not be assumed to apply by analogy to naturally resistant strains if and when they arise. The relation of artificially acquired and naturally acquired resistance to chemotherapeutic agents involves many questions as yet unanswered.

SUMMARY

Streptomycin resistance of gonococci and meningococci was determined by inoculating series of blood agar plates containing graded concentrations of streptomycin and noting the highest concentration which permitted the development of any colonies in forty-eight hours. The original or native streptomycin resistance of six strains of gonococcus was found to be between 8 and 40 units per cubic centimeter and of ninety-six strains of meningococcus 1 to 40 units per cubic centimeter.

Repeated cultivation of gonococci and meningococci on mediums containing increasing concentrations of streptomycin enhanced their streptomycin resistance rapidly —within four to six transfers—to such a degree that growth occurred on concentrations of 75,000 units per cubic centimeter, the highest concentration employed. These streptomycin resistant meningococci remained fully virulent for mice and produced lethal infections with generalized sepsis in spite of treatment with 15,000 units of streptomycin, the maximum dosage tolerated by the animals. Similar infections with the same strains before they had become resistant were regularly cured by doses of 70 to 100 units of streptomycin.

Streptomycin resistant meningococci were susceptible in vitro and in vivo to penicillin, and penicillin resistant meningococci were susceptible to streptomycin in vitro and in vivo.

Gonococci resistant to either drug were susceptible to the other in vitro.

Streptomycin resistant micro-organisms did not show the gross and microscopic abnormalities observed in penicillin resistant strains.

It must be concluded that the mode of action of streptomycin on these micro-organisms differs from that of penicillin.

RHEUMATIC FEVER ON THE ISTHMUS OF PANAMA

COLONEL MAURICE HARDGROVE
MAJOR LAMONT WHITTIER
and
MAJOR ELMER R. SMITH
Medical Corps, Army of the United States

Medical literature leads one to believe that rheumatic fever is an uncommon disease in the tropics. It suggests also that when the disease does occur it is mild and cardiac damage is slight. Manson-Bahr[1] states that "as rheumatic fever is a rare disease in the tropics, rheumatic affections of the valves of the heart are correspondingly rare." J. T. Clarke[2] stated that rheumatic fever is practically unknown at sea level in tropical areas. W. T. James[1] has been quoted by Manson-Bahr as stating that he had not seen a case of rheumatic fever in twenty-four years of practice in Panama. Goetz[3] found rheumatic heart lesions in 3 autopsies on native Panamanians. He also reported 3 cases of chorea and 5 cases of rheumatic fever among 11,000 admissions to Santo Tomas Hospital in Panama City. Chanis[4] gave an excellent description of rheumatic lesions found in 12 native Panamanian patients who died in Santo Tomas Hospital. Acute lesions caused by rheumatic fever accounted for 5 deaths, and cardiac failure resulting from healed rheumatic valvulitis caused death in the remaining 7 patients.

SOURCE OF MATERIAL

The number of cases of active rheumatic fever in Gorgas Hospital prompted this review of the clinical and postmortem records of the hospital. The records were studied separately by each of us and after complete agreement the cases were classified. Only patients having either typical cardiac or joint involvement were included. Those in whom the findings were not clearcut or adequately described, but in whom the diagnosis of rheumatic fever seemed probable, were considered as "possible" cases. If further doubt existed, they were not included in this report.

From the Medical and Pediatric Services of Gorgas Hospital, Ancon, Panama Canal Zone.

ANALYSIS OF CASES

Prior to 1930, only 8 cases meeting the aforementioned requirements were found in 8,905 autopsy records of the Board of Health Laboratory. Five were classified as acute and active rheumatic fever, and the other 3 were found to be healed rheumatic lesions.

The earliest record was that of a Spaniard who died in 1908 at the age of 50 years after a residence of only eight months on the Isthmus. Autopsy revealed a healed mitral lesion. The next patient was a Negro aged 44 who died in January 1919 of active rheumatic fever after living ten years on the Isthmus. He was originally from the French West Indies. The 4 other patients with active rheumatic fever were born and had always lived on the Isthmus. Only 1 of the patients with inactive rheumatic fever was born here.

Table 1.—*Analysis of the Incidence of Rheumatic Fever in 310,718 Hospital Admissions Between Jan. 1, 1904 and Dec. 31, 1930*

Total	170	7	44	34	28	57	

Fourteen cases of well defined active rheumatic fever were found among 310,718 clinical records of the hospital between 1904 and 1930. Seven of the patients were of British West Indian parentage, 3 were Panamanian and 3 were born in the United States. One other was a transient Danish seaman. Eight of the 14 had been born and had always lived on the Isthmus. The earliest well defined case in this group was noted in 1910. The patient was a boy aged 12 years, born in the United States, who had lived on the Isthmus four years. An additional 14 cases resembling rheumatic fever were found during this period (table 1).

There were 228,748 admissions to Gorgas Hospital during the fourteen years that began Jan. 1, 1930 and ended Dec. 31, 1943. The hospital charts reviewed for these years showed a decided increase in the incidence of rheumatic fever. It is with this period that the statistics given here deal. Autopsy records of the Board of Health Laboratory were also studied for the same period. Since 1940 all patients have been seen by one or more of us.

A. *Active Rheumatic Fever.*—Since 1930, 80 persons were considered to have definite acute and active rheumatic fever. Twenty of this group died while in the hospital. All of the deaths were due to acute rheumatic carditis. Seventy-six of the 80 patients had definite rheumatic cardiac involvement. Two others were considered clinically to have possible cardiac involvement, but the remaining 2 had no diagnostic signs of heart damage. Fourteen of the 20 who died and in whom autopsies were performed had acute pancarditis.

Sixty-five of these 80 patients were born and had always lived on the Isthmus. Ten of the remaining 15 were born in the United States, 4 in the West Indies and 1 in Colombia. Forty-six were of West Indian parentage, 21 were Panamanians and 12 were born of white parents from the United States (table 2).

Nineteen of the 20 patients who died were born on the Isthmus. These included 12 West Indians, 5 Panamanians and 2 whose parents were born in the United States. The other one was born in Jamaica but had lived here for twenty years.

Only 5 of the 80 patients were under 5 years of age when first admitted to the hospital with rheumatic fever. Thirty-two were in the age group of 5 to 10 years, 17 were 11 to 15, 13 were between 16 and 20 and 13 were over 20. Fourteen of the deaths occurred between the ages of 5 and 10 years. Four of the 5 who were less than 5 years old died. Thus 18 of the 20 deaths from the disease occurred under 11 years of age (table 3).

Females slightly outnumbered the males, there being 43 females and 37 males. Ten females and 10 males died as the result of acute attacks of rheumatic fever.

There were 109 hospital admissions for rheumatic fever among these 80 patients, an average of 1.36 admissions per individual.

B. *Possible Active Rheumatic Fever.*—Thirty-four patients with possible acute rheumatic fever were studied (tables 2 and 3). Of these, 22 were born and had always lived on the Isthmus. There were 17 West Indians, 4 Panamanians and 1 of white United States parentage. Twelve were born in the United States and had been here from two weeks to two and a half years. Most of this transient group were soldiers.

There were 2 deaths among the 34 patients, but autopsies were not obtained. The 2 who died were West Indian girls aged 4½ and 11 years respectively. They were born on the Isthmus and died on their first hospital admission.

Only 2 patients were 4 years of age or younger at the time of their first admission. Eight were 5 to 10 years of age, 8 were 11 to 15, 7 were 16 to 20 and the remaining 9 patients were more than 20. Twenty-one were males and 13 were females.

C. *Inactive Rheumatic Valvular Lesions (Healed).*—Definite rheumatic valvular lesions were found in 56 patients who showed no evidence of rheumatic activity (tables 2 and 3). There were 28 deaths in this group. The clinical diagnosis of healed rheumatic heart disease was confirmed at autopsy on 20 patients. Ten of these had complications: 6 had subacute bacterial endocarditis due to Streptococcus viridans, 3 had acute bacterial endocarditis due to other organisms and 1 died of malaria. Among the 8 patients who died but on whose bodies autopsies were not held there were 5 who had positive blood cultures for Str. viridans and 1 for pneumococci. Two died in simple cardiac failure. In addition to these 28 deaths, there were 5 other patients among the 56 who had positive blood cultures (4 positive for Str. viridans and 1 for Staphylococcus aureus). However, they left the hospital and there is no record of autopsies. Thus there were 15 patients with subacute bacterial endocarditis (Str. viridans) superimposed on old healed rheumatic endocardial lesions.

The most common ages in which the healed valvular lesions were recognized in the Isthmus born group (32 patients) were between 11 and 20 years (17). All but 24 were born and had always lived in Panama. Fifteen were born in the United States, 7 in the West Indies, 1 in Poland, and the birthplace was unknown in the other. There were 26 males and 30 females in this group.

COMMENT

The patients classified as West Indians were of British or less frequently French West Indian parents who came to work for the Panama Canal either during early construction days or at a later period. Most of the British West Indians were of pure Negro stock, spoke English and had English surnames. Many of those who had rheumatic fever were of the second generation, their parents having been born on the Isthmus.

Panamanians were born locally and were of mixed blood, including combinations of white (usually Spanish), native Indian and black West Indian. These mestizo patients were all of the laboring class.

The isthmus of Panama is located 9 degrees north of the equator. The dry season is from January through April and the wet season from May through December. On the Pacific side of the Isthmus, where Gorgas Hospital is located, the average yearly maximum temperature is 87.3 F.; the average yearly minimum is 73 F. The average relative humidity is 83 per cent. There appeared to be no relationship between the admissions for rheumatic fever and the season of the year (rainy or dry), nor was there a significant yearly variance in the admissions for the disease.

The high percentage of cardiac involvement among the 80 patients with acute rheumatic fever may be due in part to our hesitation in classifying as active rheumatic fever those cases without some indication of cardiac damage. Only 1 patient escaped cardiac involvement of 16 with acute rheumatic fever treated in the colored pediatric ward from January 1941 to July 1943. Three of the 16 patients died of acute rheumatic pancarditis, and ten of the remaining 13 had symptoms and clinical signs of extensive cardiac damage. Nodes were not mentioned in the old charts, and more recently they have been found in only 1 patient. Chorea occurs in native born children, but those cases seen since 1940 have been mild.

Preliminary upper respiratory infections did not occur regularly in recent cases of rheumatic fever. Although scarlet fever occurs here, it is seldom seen in a severe form.[5] There is no record in the cases reviewed of acute rheumatic fever following shortly after scarlet fever.

It is apparent that rheumatic fever occurs in natives as well as in others who come to the Isthmus from elsewhere. This statement applies both to the initial attack and to recurrence of the disease. The mitral and aortic valvular lesions occur in similar proportions to cases seen in the United States (e. g. Wisconsin).[6]

It would appear from the available material that the incidence of rheumatic fever began to increase slowly about 1927 and since 1930 has become a rather common problem in the pediatric and medical wards in this hospital.

There are no tenable explanations for the increase in the incidence of the disease. The ability of the clinicians and pathologists of the earlier day precludes any assumption that the disease went unrecognized. Dr. Deeks, Dr. Darling, Dr. Connor, Dr. H. Clark, Dr. W. T. James, Dr. H. C. Dooling and Dr. L. B. Bates are to mention but a few of the well trained men who were observing cases either at the bedside or at the autopsy table between 1904 and 1930. It does not seem likely that the disease was brought to the Isthmus by workers from the United States. There has always been a regular yearly rate of travel between the Isthmus and the United States as the result of changes in personnel and in connection with vacations. There have been two main periods of influx of new employees in large numbers. The first was during the early construction days from 1904 to 1906, and the second more recent period was during 1940 and 1941. Rheumatic fever was uncommon following the first period and had ceased to be a rarity before the last. The variation in the total population does not explain the increase. The climate has not changed. Milk has not been nor is it now used abundantly by the natives, but it has always been an adequate part of the diet of children of workers from the United States. The native diets are fairly adequate, as frank deficiency diseases are extremely rare. No relationship between associated tropical diseases, e. g. intestinal parasites, malaria and yaws, has been demonstrated. Additional reports on the common occurrence of rheumatic carditis in tropical and subtropical regions have appeared in recent literature.[7]

CONCLUSION

Rheumatic fever is not uncommon in Panama. The course of the disease, as well as the resultant cardiac damage, resembles that found in the United States.

Clinical Notes, Suggestions and New Instruments

SUDDEN DEATH FOLLOWING INTRAVENOUS INJECTION OF THIAMINE HYDROCHLORIDE

IRVING M. REINGOLD, M.D., and FRANK R. WEBB, M.D.
Los Angeles

There have been several reports in the literature of adverse effects following the parenteral administration of thiamine hydrochloride. Most of the untoward reactions were in the nature of hypersensitivity to the vitamin, and in only one report was a death recorded. Recently another death occurred following the intravenous administration of a solution of thiamine hydrochloride, and since vitamins are now being introduced parenterally in large quantities it seems fitting to describe this case and record the autopsy findings.

REVIEW OF THE LITERATURE

Mills[1] reported the first death in man due to an intramuscular injection of thiamine hydrochloride; at autopsy multiple ecchymoses beneath the pia over both cerebral hemispheres, with areas of encephalomalacia and perivascular hemorrhages, were found. Stern[2] described a case of "vitamin B_1 poisoning" of a cat in which 20,000 international units of the vitamin were injected via cisternal puncture. In coming out of the anesthesia the animal became very irritable, with rapid respirations and nystagmus, ending in generalized convulsions. The rapid respirations were interrupted by periods of apnea, which occurred about every four minutes; the animal died in fifty minutes.

Several reactions following the parenteral injections of a solution of thiamine hydrochloride have been observed. Stern[2] found that 15,000 international units injected into the lumbar subarachnoid space was apt to produce weakness, conjunctivitis, loss of appetite, buzzing in the ears, stiffness of the muscles and slight fever. Steinberg[3] noted the development of herpes zoster on the side of the chest in 2 patients who had been given 2,000 international units of thiamine hydrochloride intravenously weekly for several weeks, and in another who had been given 1,200 international units by mouth daily for a period of two weeks. Two other patients given parenteral injections complained of nausea and a sense of constriction of the throat. Mills[4] observed symptoms similar to those of thyroid hyperactivity, namely fine and coarse muscle tremors, rapid pulse and noticeable nervous hyperirritability, in patients taking thiamine hydrochloride orally over a period of time. Laws[5] reported that a woman was given daily, then weekly, subcutaneous injections of thiamine hydrochloride. After many of these injections, and after leaving the physician's office, she would sneeze violently several times, and the site of injection would itch for several hours. Ten days elapsed before her final injection, after which she developed generalized urticaria, edema of the face, dyspnea, cyanosis and wheezing. Intracutaneous and passive transfer tests indicated that the patient was sensitive to thiamine hydrochloride. Stiles[6] observed 2 patients in whom prolonged administration of thiamine hydrochloride produced hypersensitivity to it. One patient complained of nervousness associated with flushing and tachycardia, the other a sensation of heat and profuse perspiration. Schiff's patient[7] collapsed after having received parenteral injections for several months. She had had short bouts of nausea and sneezing after several injections. Intradermal tests indicated that she was sensitive to an aqueous solution of thiamine hydrochloride. Eisenstadt[8] added 2 cases of his own to the literature in which the patients showed allergic reactions to parenteral administration of the vitamin but who were able to tolerate it orally without adverse effects. His patients were positive to the intradermal tests but negative to the passive transfer tests. He suggested, as did Laws,[5] that patients who are about to receive thiamine hydrochloride parenterally should be skin tested as a precautionary measure. One of Leitner's patients[9] developed an asthmatic-like attack with eosinophilia after a long course of parenteral injections; the other had symptoms resembling those of thyroid overdosage. Intradermal tests with thiamine were positive. Stein and Morgenstein[10] report that a young man who received large doses of thiamine hydrochloride parenterally (from 15,000 to 30,000 international units) at first several days apart, and later at approximately monthly intervals, developed itching and a large wheal at the site of inoculation after each injection. After the last injection he collapsed; he perspired profusely, was dyspneic and cyanotic and had wheezing breath sounds. He recovered the next morning, after stimulants had been given. Later an intradermal test with a saline solution of thiamine hydrochloride was positive.

REPORT OF CASE

History.—A white woman aged 25, married, who weighed 155 pounds (70 Kg.) and measured 5 feet 10 inches (178 cm.) in height, whose past history was essentially negative and who had had measles and chickenpox as a child and pneumonia many years previously, had gone to her physician complaining of nervousness, tiredness and moderate low backache. Her physician's examination was essentially negative; the blood pressure was 116/64 and the pulse rate 90.

On Oct. 1, 1945 1 cc. of a solution of 100 mg. of thiamine hydrochloride (33,330 U. S. P. units) with 0.5 per cent chlorobutanol added as a preservative was injected intravenously. Immediately following the injection the patient complained of a generalized burning and perspired moderately. Within a few minutes, however, she stated that she felt fine. She returned to her physician's office on October 4, and after stating that she had had no untoward reactions at home during the interval she was given another injection intravenously of the same preparation. This time she had no ill effects. On October 20 the injection was repeated; again there were no complaints.

On November 6 the patient returned to the physician's office and complained of being jittery. Again 1 cc. of a solution of 100 mg. of thiamine hydrochloride was introduced intravenously. This time the patient complained of a generalized burning sensation; she perspired profusely. Within a few moments she became dyspneic and cyanotic. She was given 1 cc. of a solution of 1: 1,000 epinephrine hydrochloride subcutaneously but soon lost consciousness and died. Her death occurred probably less than ten minutes after the injection of the thiamine hydrochloride had been given. Of importance was the fact that two similar injections from the same bottle had been given to 2 other patients the same day without untoward reactions.

Report of Autopsy.—The body was well developed and well nourished. In the right antecubital fossa was a small, recent area of hemorrhage in the subcutaneous tissue. Testing for air emboli revealed none in the heart. There was moderate dilatation of the right auricle and moderate fatty infiltration of the myocardium of the right and left ventricles. All lobes of the lungs were crepitant; there were a few areas of moderate firmness and granularity. The abdominal organs were hyperemic. In the brain there was a moderate hyperemia.

Microscopically the important features were the dilatation and engorgement of the veins and sinusoids of the viscera and the changes seen in the lungs. Besides the engorgement of the

pulmonary vessels there were areas of emphysema in which the alveoli were overdistended and the septums ruptured. Occasional alveoli disclosed numerous brown pigmented macrophages suggestive of previous hemorrhages. The septums in many areas were thickened and infiltrated with a few polymorphonuclear leukocytes and round cells. The bronchioles were dilated in some areas and collapsed in others: there was some desquamation of the bronchiolar epithelium and infiltration of round cells into the walls.

COMMENT

We believe that this case is an example of death due to anaphylactic shock. The anaphylactogen was thiamine hydrochloride.

In order to achieve active anaphylaxis, the following conditions must be fulfilled: (1) the preparatory or anaphylactizing contact, (2) an appropriate period of latency, during which the organism produces antibodies, and (3) the subsequent, eliciting contact.[11] The allergization takes place as the result of numerous repeated exposures to the antigen.

The requirements for the production of active anaphylaxis, hence, were met in this patient. She had received three previous injections of the anaphylactogen; the necessary period of latency occurred; the eliciting contact was followed by death.

Anaphylaxis in human beings may evoke a variety of clinical manifestations; it is assumed that these manifestations are due to the antigen-antibody reaction either in the smooth muscle or in the capillary endothelium. In the guinea pig the characteristic feature is bronchial constriction and asphyxiation, in the rabbit constriction of pulmonary arteries and right heart failure, and in the dog fall in blood pressure.[12]

Pathologically the anaphylactic shock in this patient probably manifested itself in constriction of the pulmonary arteries with the production of pulmonary engorgement and right heart dilatation and failure. There apparently was an associated constriction of bronchioles and consequently a mild emphysema. Of interest was the finding of small foci of polymorphonuclear leukocytes and round cells in thickened septums, giving the picture of an early interstitial pneumonia. The numerous pigmented macrophages present in several alveoli might have been the result of small hemorrhages occurring after the previous anaphylactizing injections.

It is unlikely that the preservative, chlorobutanol, constituted the anaphylactogen; the amount present in the solution was extremely small. Besides, previous authors [13] had found that their patients were hypersensitive to an aqueous solution of the vitamin but not to chlorobutanol. Furthermore, it is unlikely that pyrogens were present in the vitamin preparation, since 2 other patients had been given the same preparation on the same day without ill effects.

Vitamins, like other foodstuffs, are best taken by mouth. Where parenteral administration of thiamine hydrochloride is justified, skin tests of the patient using the vitamin preparation as the allergen should be done.

CONCLUSIONS

1. Sudden death followed an intravenous injection of a solution of thiamine hydrochloride.
2. The patient had been given four injections at frequent intervals prior to death. Following the last injection she complained of a generalized burning, perspired profusely, became dyspneic and cyanotic and soon died.
3. The death is considered an example of an anaphylactic shock, the thiamine hydrochloride being the anaphylactogen.
4. Pathologically, the anaphylaxis probably manifested itself in constriction of the smooth muscles of the pulmonary arteries and bronchioles, resulting in pulmonary engorgement and right heart dilatation and failure, and in mild pulmonary emphysema, respectively. In addition, small foci of polymorphonuclear leukocytes and round cells were seen in thickened septums of pulmonary alveoli. Foci of pigmented macrophages probably indicated that previous hemorrhages had occurred following an anaphylactizing injection.

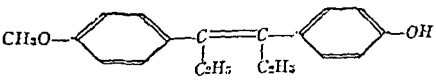
MONOMESTROL.—Mestilbol.—Diethylstilbestrol monomethyl ether. — 3-*p*-Hydroxphenyl-4-*p*-methoxyphenyl-3-hexene. —*a,a'*-Diethyl-4'-methoxy-4-stilbenol. — $C_{19}H_{22}O_2$ (Molecular weight 282.37). Monomestrol may be represented by the following structural formula:



It may be prepared by methylation of diethylstilbestrol or by partial demethylation of the dimethyl ether of diethylstilbestrol. The crude product may be purified by distillation in vacuum and recrystallization from water-alcohol or from benzene-petroleum ether mixtures.

Actions and Uses.—Monomestrol is used for the same conditions for which estrogenic substances are employed, and the contraindications are essentially the same. Like other estrogens, it must be individualized since each patient presents special problems. Patients undergoing treatment should remain under constant medical supervision. Side effects are rare, but when they do occur they are usually mild, although in a few instances it may be necessary to reduce the dosage temporarily.

Dosage.—The average oral dose for the treatment of menopausal symptoms is 0.5 to 1 mg. daily by mouth, although if necessary 10 to 25 mg. may be given parenterally biweekly. Dosage for atrophic genital disorders such as kraurosis vulvae include 1 to 5 mg. daily by mouth or 25 mg. weekly by parenteral injection; for gonorrheal vaginitis of children 0.25 mg. daily; for the prevention of breast engorgement 5 to 10 mg. daily or 25 mg. the first and third days by injection; for suppression of lactation 10 mg. two or three times daily, or 25 mg. daily by injection; for prostatic cancer 2.5 mg. three times daily by mouth. The duration of treatment varies and may last for several months or even two or three years in the treatment of the menopause, a few weeks for gonorrheal vaginitis in children, a few months for atrophic genital disorders, three to five days for prevention of breast engorgement and suppression of lactation or be continuous for prostatic cancer.

Tests and Standards.—

Monomestrol occurs as an odorless, white, crystalline powder, which melts at 116-117.5 C. when recrystallized from benzene-petroleum ether (112-114 C., when recrystallized from alcohol). It is soluble in alcohol, freely soluble in acetone and in ether and practically insoluble in water, in dilute mineral acids and in dilute aqueous solutions of sodium and potassium hydroxide. It may be dissolved in vegetable oils and in dilute solutions of sodium or potassium hydroxide in 50 per cent ethanol.

To 1 mg. of monomestrol dissolved in 5 cc. of alcoholic potassium hydroxide add diluted hydrochloric acid to neutralize the solution and then add 1 cc. in excess. Add 1 cc. of molybdophosphotungstate reagent and shake. Allow to stand ten minutes, dilute to 25 cc. with water and add 5 cc. of saturated sodium carbonate solution: a blue color develops on standing. Add a few drops of 50 per cent solution of antimony pentachloride in dry *alcohol-free* chloroform to a dilute solution of monomestrol in the same solvent: a red colored solution is produced which changes rapidly to purple *(distinction from hexestrol, which gives no color).*

Dissolve 10 mg. of monomestrol in 5 cc. of concentrated sulfuric acid: an orange color is produced which disappears on dilution with water *(distinction from hexestrol and benzestrol, which give no color).*

Dry an accurately weighed specimen of monomestrol at 100 C. for four hours: the loss does not exceed 0.5 per cent. Ignite an accurately weighed specimen of monomestrol after the addition of concentrated sulfuric acid: the sulfated ash residue is not more than 1 per cent.

Transfer 0.1 Gm. of monomestrol to a 100 cc. volumetric flask and dilute to the mark with carbon tetrachloride. Transfer 10 cc. of the solution to a 250 cc. iodine flask fitted with an accurately ground stopper; add the calculated quantity plus 1 cc. of tenth-normal bromide-bromate solution (prepared according to the U. S. P. XII, p. 749); wash the walls of the flask and wet the stopper by the addition of 10 cc. of distilled water. Quickly add 10 cc. of 10 per cent hydrochloric acid and insert the wet stopper. Shake the mixture thoroughly for several minutes, then set aside in the dark at 30 C. and shake intermittently for exactly fifty minutes. At the end of this period place 2 cc. of 40 per cent potassium iodide solution around the stopper. Remove the stopper just enough to allow the potassium iodide solution to enter the flask, shake thoroughly, rinse the stopper and sides of the flask with distilled water, add 25 cc. of carbon tetrachloride and titrate with fiftieth-normal sodium thiosulfate to the disappearance of the pink color in the carbon tetrachloride. Each cubic centimeter of tenth-normal bromide-bromate solution is equivalent to 4.706 mg. of monomestrol. The monomestrol content is not less than 99 per cent.

nature of the reaction between bromine and monomestrol leads to complications unless the conditions of a given procedure are strictly observed. This method of standardization must be considered tentative until more accurate analytic procedures are available.

The following dosage forms have been accepted:

Wallace & Tiernan Products, Inc., Belleville, N. J.

Tablets Monomestrol: 0.25 mg., 0.5 mg., 1.0 mg., 2.5 mg. and 5.0 mg.

Solution Monomestrol 10 mg. and 25 mg. per cc. (in Sesame Oil): 1 cc. ampuls.

PROCAINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1945, p. 97).

The following dosage form has been accepted:

George A. Breon & Co., Inc., Kansas City, Mo.

Solution Procaine Hydrochloride 2% W/V: 30 cc. vials. Each cubic centimeter contains 20 mg. procaine hydrochloride in isotonic solution of sodium chloride with chlorobutanol 0.5 per cent as a preservative.

PERTUSSIS VACCINE COMBINED WITH DIPHTHERIA TOXOID (See The Journal, Jan. 5, 1946, p. 31).

The following dosage form has been accepted:

Parke, Davis & Co., Detroit

Diphtheria Toxoid-Pertussis Vaccine Mixed (Sauer): 6 cc. vials (one immunization) and 24 cc. vials (four immunizations).

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report: Howard A. Carter, *Secretary.*

SUN-KRAFT COLD QUARTZ ULTRAVIOLET RAY THERAPY LAMP NOT ACCEPTABLE

Manufacturer: Sun-Kraft Incorporated, Sun-Kraft Building, 215-217 West Superior Street, Chicago 10.

In the issue of The Journal dated June 19, 1943, page 505, the Council on Physical Medicine published a report setting forth its reasons for proclaiming the Sun-Kraft Lamp unacceptable as a "sun lamp."

In view of the renewed inquiries regarding this device the Council has given further consideration to the acceptability of the Sun-Kraft Lamp, which is now labeled "Cold Quartz Ultraviolet Ray Therapy Lamp."

Construction.—The Sun-Kraft Cold Quartz Ultraviolet Ray Therapy Lamp, Model A-1, consists of a quartz tube about 6 inches (15 cm.) long and about ½ inch (1.2 cm.) in diameter containing a globule of mercury. The quartz tube is supported in a small semicylindric, chromium plated reflector. It is energized by radio frequency current, without internal wires. In the sample tested, when operated on 110 volts alternating current, the lamp consumed 26 watts, in close agreement with the claims made for it.

A small folder entitled "Sun-Kraft Cold Quartz Ultraviolet Ray Therapy Lamp" emphasizes that "it is not a Sun Lamp because its radiation of 95 per cent ultraviolet rays" [presumably the biologically effective component ultraviolet of wavelengths shorter than 3,200 angstroms is meant] are always cold and always constant in intensity, no matter how long or how often it is used." "Sun-Kraft ultraviolet rays are cold, purposely so, because heat dissipates ultraviolet rays"—an absurd claim. The peak of intensity at 2,537 angstroms is stated to be important as "it induces vitamin D production and is a powerful germicidal agent." The following are some of the questionable statements made in this folder: "The intensity is kept low to minimize any danger of overexposure." "Compilation of many years of medical research proves conclusively that ultraviolet rays, invisible to the human eye, kill bacteria, induce vitamin D, strengthen bones and teeth, and help the body resist ailments." "Ultraviolet rays stimulate circulation and aid in relieving discomforts, pain caused by respiratory ailments, such as head colds, sinus, bronchitis, asthma, hay fever, etc." "Medical science also states that ultraviolet rays aid in relieving arthritis and muscular pains. . . ." Some of these claims are either exaggerated or misleading as applied to this lamp; others are not acceptable in sales promotion.

In a booklet on "How to Use Your Sun-Kraft Cold Quartz Ultraviolet Therapy Lamp" indications are given for use of the lamp in (*a*) producing vitamin D; (*b*) treating acne, eczema, psoriasis, athlete's foot; (*c*) treating respiratory conditions, asthma, sinus, bronchitis, hay fever, catarrah and colds, by exposure to ultraviolet rays and, in addition, by *inhaling ozone* by placing the nose close to the back side of the reflector, six to twelve minutes, twice per day; (*d*) treating arthritis, rheumatism and neuritis; (*e*) producing an even facial burn (tanning); (*f*) treatment of hair and scalp; (*g*) irradiation of children; (*h*) activation of vitamin D in milk and food products, and (*i*) sterilization of air. For the latter purpose it is asserted that the ultraviolet rays and activated ozone will sterilize your room, reducing the bacterial content of the air; also that Sun-Kraft serves as a larva destroyer and deodorizer of your wardrobe closet. All of these are unwarranted or exaggerated claims. In this booklet the novel, physically absurd, assertion is made that "powerful 'Sun-Lamps' mix their ultraviolet rays with intense visible light and heat rays, which dissipate most of the ultraviolet rays before they reach the body." It is further asserted that "ultraviolet rays are eagerly absorbed by the air; the further you are from the quartz tube the less effective the rays." The latter part of this assertion is true; but absorption by the air is not the real cause of the loss in effectiveness, which is due to the rapid decrease in intensity with distance from the lamp.

Because of the low intensity it is recommended to operate the lamp at 6 inches or less. To determine the best timing and distance for each individual, an exposure of one minute at a distance of 1 inch from the edge of the reflector is recommended, two minutes at 2 inches and six minutes at 6 inches. This is just the reverse of trials with powerful ultraviolet lamps where a great distance is used in the first trials to prevent burns from overexposure.

Radiometric measurements on a Sun-Kraft lamp, made in a physical laboratory acceptable to the Council, showed that at distances of 6 inches (15 cm.) and shorter the field of irradiation was very nonuniform in intensity because of focusing of images of the quartz tube by the reflector. This nonuniformity was in three long, narrow bands (each one less than 2 cm. in width) differing by 15 to 20 per cent or more in intensity. Moreover, the total field of irradiation was small (about 10 by 20 cm.).

The following intensities, measured at right angles to the cylindric axis of the lamp (on 26 watts), were observed: at 3 inches, 190 microwatts per square centimeter; at 6 inches, 83 microwatts per square centimeter; at 24 inches (which is the minimum acceptable operating distance), 6 microwatts per square centimeter. The latter value is only one sixth of the specified minimum value (36 microwatts per square centimeter for cold quartz lamps) as required for acceptability by the Council for use as a therapeutic lamp. The ultraviolet output is about one tenth of the minimum value acceptable for use as a disinfecting lamp, and only about one fifteenth the intensity of the ultraviolet lamps used for disinfecting purposes. Exposure of the untanned inner forearm at 6 inches (15 cm.) from the lamp produced a minimum perceptible erythema in twelve to fourteen minutes in agreement with the radiometric measurements close to the lamp.

The radiometric findings show that the ultraviolet output of the Sun-Kraft model A-1 lamp, in total intensity, does not meet the Council's requirements for acceptability for use either (1) as a sun lamp (also in spectral quality) for home use or (2) as a therapeutic lamp prescribed by a physician for home use or (3) as an ultraviolet disinfecting lamp.

Furthermore, in addition to the foregoing shortcomings, because of the scientifically incorrect, misleading (even the name "Sun-Kraft" is misleading), and unfair sales promotion; the unsubstantiated claims made; and also because of the recommended inhalation of ozone, which is known to be highly toxic and irritating to the bronchial tract, the Council on Physical Medicine reiterates its declaration of unacceptability of the Sun-Kraft Cold Quartz Ultraviolet Ray Therapy Lamp for inclusion in its list of accepted devices.

SATURDAY, FEBRUARY 23, 1946

THE AMERICAN MEDICAL ASSOCIATION HEALTH PROGRAM AND PREPAYMENT SICKNESS INSURANCE PLANS

At the annual session of the American Medical Association in Chicago in December the House of Delegates adopted a resolution instructing "the Board of Trustees and the Council on Medical Service and Public Relations to proceed as promptly as possible with the development of a specific national health program, with emphasis on the nationwide organization of locally administered prepayment medical plans sponsored by medical societies."

At a series of meetings held in Chicago beginning February 13 the Board of Trustees and the Council on Medical Service completed considerations which made possible a long step toward protecting the American people against the costs of sickness.

The fundamental step in the development of this plan was the establishment of standards of acceptance for medical care plans which have the approval of the Council on Medical Service of the American Medical Association. Any plan which meets the standards of the Council will be entitled to display the seal of acceptance of the American Medical Association on its policies and on all of its announcements and promotional material. In order to qualify for acceptance, the prepayment plan must have the approval of the state or county medical society in the area in which it operates. The medical profession in the area must assume responsibility for the medical services included in the benefits. Plans must provide free choice of a qualified doctor of medicine and maintain the personal, confidential relationship between patient and physician. The plans must be organized and operated to provide the greatest possible benefits in medical care to the subscriber.

Medical care plans may be in terms of either cash indemnity or service units, with the understanding that benefits paid in cash are to be used to assist in paying the costs incurred for medical service. The standards also include provisions relative to the actuarial data that are required, systems of accounting, supervision by appropriate state authorities and periodic checking and reporting of the progress of the plan to the Council.

Coincidentally with the announcement of these standards of acceptance there was organized, as a voluntary federation, an organization known as Associated Medical Care Plans, Inc. This independent association will include as members all plans that meet the minimum standard of the Council on Medical Service of the American Medical Association. The Associated Medical Care Plans will undertake to establish coordination and reciprocity among all of these plans to permit transference of subscribers from one plan to another and use of the benefits in any state in which a subscriber happens to be located. Under this method great industrial organizations with plants in various portions of the United States will be able to secure coverage for all their employees. Moreover, it will be possible for the Veterans Administration, welfare and industrial groups and government agencies to provide coverage for the people in any given area through a system of national enrolment. In addition the Associated Medical Care Plans, Inc., will undertake research and the compilation of statistics on medical care, provide consultation and information services based on the records of existing plans and engage in a great campaign of public education as to the medical service plan movement under the auspices of state and county medical societies.

The Board of Trustees of the American Medical Association also announced establishment of a Division of Prepayment Medical Care Plans with a director and a staff who will administer the activities related to the promotion and development of medical care plans in all the states.

In announcing these proposals for a nationwide provision of sickness insurance on a mutual nonprofit basis, the Board also presented a complete health program with ten points, which include the development of services in the field of preventive medicine, maternal and child health, voluntary prepayment plans for protection against the costs of sickness, compensation for loss of wages due to illness, the care of the veteran and the development of a high standard of housing, nutrition, clothing and recreation.

The American Medical Association last June through its Board of Trustees and Council on Medical Service announced a fourteen point program to improve the health and medical care situation in the United States. In October 1945 the interpretation of these fourteen points and methods of implementation were adopted by the Council on Medical Service. In December 1945 the House of Delegates approved the whole program, suggested its rearrangement and directed the Board of Trusteees to keep the program constantly up to date so that it will stay at least even with and, if possible, a step ahead of the needs of the public.

With this in mind the Board of Trustees has adopted a restatement of the fourteen point program, which clarifies still further the position of the American Medical Association on some of these points and brings into the program more definitely maternal and child welfare, medical research, the medical care of the veteran and the part to be played by the voluntary health agencies.

This restatement follows:

National Health Program of The American Medical Association

1. The American Medical Association urges a minimum standard of nutrition, housing, clothing and recreation as fundamental to good health and as an objective to be achieved in any suitable health program. The responsibility for attainment of this standard should be placed as far as possible on the individual, but the application of community effort, compatible with the maintenance of free enterprise, should be encouraged with governmental aid where needed.

2. The provision of preventive medical services through professionally competent health departments with sufficient staff and equipment to meet commmunity needs is recognized as essential in a health program. The principle of federal aid through provision of funds or personnel is recognized with the understanding that local areas shall control their own agencies as has been established in the field of education. Health departments should not assume the care of the sick as a function, since administration of medical care under such auspices tends to a deterioration in the quality of the service rendered. Medical care to those unable to provide for themselves is best administered by local and private agencies with the aid of public funds when needed. This program for national health should include the administration of medical care, including hospitalization to all those needing it but unable to pay, such medical care to be provided preferably by a physician of the patient's choice with funds provided by local agencies with the assistance of federal funds when necessary.

3. The procedures established by modern medicine for advice to the prospective mother and for adequate care in childbirth should be made available to all at a price that they can afford to pay. When local funds are lacking for the care of those unable to pay, federal aid should be supplied with the funds administered through local or state agencies.

4. The child should have throughout infancy proper attention, including scientific nutrition, immunization against preventable disease and other services included in infant welfare. Such services are best supplied by personal contact between the mother and the individual physician but may be provided through child care and infant welfare stations administered under local auspices with support by tax funds whenever the need can be shown.

5. The provision of health and diagnostic centers and hospitals necessary to community needs is an essential of good medical care. Such facilities are preferably supplied by local agencies, including the community, church and trade agencies which have been responsible for the fine development of facilities for medical care in most American communities up to this time. Where such facilities are unavailable and cannot be supplied through local or state agencies, the federal government may aid, preferably under a plan which requires that the need be shown and that the community prove its ability to maintain such institutions once they are established (Hill-Burton bill).

6. A program for medical care within the American system of individual initiative and freedom of enterprise includes the establishment of voluntary nonprofit prepayment plans for the costs of hospitalization (such as the Blue Cross plans) and voluntary nonprofit prepayment plans for medical care (such as those developed by many state and county medical societies). The principles of such insurance contracts should be acceptable to the Council on Medical Service of the American Medical Association and to the authoritative bodies of state medical associations. The evolution of voluntary prepayment insurance against the costs of sickness admits also the utilization of private sickness insurance plans which comply with state regulatory statutes and meet the standards of the Council on Medical Service of the American Medical Association.

7. A program for national health should include the administration of medical care, including hospitalization, to all veterans, such medical care to be provided preferably by a physician of the veteran's choice, with payment by the Veterans Administration through a plan mutually agreed on between the state medical association and the Veterans Administration.

8. Research for the advancement of medical science is fundamental in any national health program. The inclusion of medical research in a National Science Foundation, such as proposed in pending federal legislation, is endorsed.

9. The services rendered by volunteer philanthropic health agencies such as the American Cancer Society, the National Tuberculosis Association, the National Foundation for Infantile Paralysis, Inc., and by philanthropic agencies such as the Commonwealth Fund and the Rockefeller Foundation and similar bodies have been of vast benefit to the American people and are a natural outgrowth of the system of free enterprise and democracy that prevail in the United States. Their participation in a national health program should be encouraged, and the growth of such agencies when properly administered should be commended.

10. Fundamental to the promotion of the public health and alleviation of illness are widespread education in the field of health and the widest possible dissemination of information regarding the prevention of disease and its treatment by authoritative agencies. Health education should be considered a necessary function of all departments of public health, medical associations and school authorities.

During the coming weeks the Council on Medical Service will announce the activities that will be followed toward promoting the prepayment medical care plan and also the standards of acceptance that have been developed for such plans. The Division of Prepayment Medical Care Plans in the headquarters office will soon be active in aiding the development of plans in areas which do not now have them and in coordinating existing plans.

The policies of the Association as expressed in the National Health Program may well suggest to legislators in the Senate and in the House the point of view of the medical profession as to the part that the federal government can play in extending necessary medical services to those who do not now have them.

ANIMAL EXPERIMENTATION

An intensification of the fight to cripple or destroy medical research by legislative prohibition of animal experimentation met its first defeat recently in the New York legislature. This conflict has been waged perennially; in some states the convening of the legislature is virtually a date to include on the medical school calendar, like the opening of the fall school session or the dates of the Christmas vacation period. Efforts to hamper or prevent animal experimentation by law are now under way in several other states, including Massachusetts and in Washington, D. C. (by Congressional action).

In New York round one was won for medical science by the effective combined efforts of the New York State Medical Society, the New York Academy of Medicine, the New York State county medical societies, the medical schools of the state and others. A telling incident in the publicity campaign was the public awarding of citations by Surgeon General Norman T. Kirk to Trixie and Josie, two dogs descended from those employed by Dr. George H. Whipple in his Nobel prize winning experiments on liver diets in blood regeneration.

The threat to medical progress by interference with animal experimentation should be met at the national level by a strong organization whose influence can supplement and coordinate local activities and maintain a continuous program of educating the public regarding the necessity, the humane character and the fruits of animal experimentation in medicine and biology. Such an organization is now under way. Under the auspices of the Association of American Medical Colleges and with the cooperation of other groups a nationwide organizing board of directors has been selected. This group met in Chicago February 11 at the time of the Congress on Medical Education and Licensure, selected the tentative name National Society for Medical Research, elected Dr. A. J. Carlson chairman and Dr. Andrew C. Ivy secretary and appointed an executive committee consisting of the chairman, the secretary and Drs. C. Sidney Burwell, Eben J. Carey, L. R. Chandler, Victor Johnson and Chauncey D. Leake. The formulation of policies and procedures was also commenced and the decision reached to employ a full time executive secretary. The materials and financial resources of the Friends of Medical Research of the state of New York have been pledged to the new organization, and many medical schools have given support and funds. Additional support must come from other medical schools, state and county medical societies, academies of medicine, national professional organizations in biology and medicine, the ethical drug houses and physicians and scientists generally.

Although medical schools have pledged at least temporary financial aid, the major financial support will be forthcoming from other sources. The experience in New York and elsewhere demonstrated that funds in large amounts can be raised for a national organization.

At the December meetings the House of Delegates of the American Medical Association approved the education of the public in the benefits both to men and to animals from animal experimentation and urged that the people of the United States be completely and thoroughly informed as to these benefits and as to the effect on further progress in research on various diseases, should such animal experimentation be forbidden in any state. Cooperation with the national movement was also urged by the House of Delegates. The Board of Trustees has authorized the development of effective campaign literature and its widest possible dissemination.

FOLIC ACID THERAPY

In 1935 Day and his associates[1] of the University of Arkansas reported that young rhesus monkeys given a diet consisting of casein, polished rice, whole wheat, salt mixture, cod liver oil and ascorbic acid develop a syndrome characterized by anemia, leukopenia, loss of weight, diarrhea and ulceration of the gums. Death usually occurs between the twenty-sixth and the one hundredth day. Supplementation of this diet with riboflavin, nicotinic acid or thiamine hydrochloride, given either alone or in combination, does not prevent the development of this lethal deficiency disease. If the daily deficiency diet is supplemented with either 10 Gm. of dried brewers' yeast or 2 Gm. of liver extract, however, normal body growth and a normal blood picture are maintained over a long period. From these experiments it seemed that yeast and liver extract contain an unknown substance essential to the nutrition of monkeys. For this unknown nutritional factor the Arkansas clinicians proposed the term vitamin M.

---

[1] Day, P. L.; Langston, W. C., and Shukers, C. F.: J. Nutrition 9:637 (May) 1935.

Five years later Snell and Peterson[2] of the University of Wisconsin showed that a certain "norite eluate factor" extractable from yeast or from liver extract is essential for the growth of Lactobacillus casei. It was afterward found[3] that this L. casei factor is curative of vitamin M deficiency in monkeys and necessary for normal growth and hemoglobin formation in chicks. A crystalline folic acid apparently identical with this L. casei factor was recently synthesized by Angier and his associates[4] of the Lederle Laboratories and made available for clinical trial.

The similarities of the sprue syndrome in man to the manifestations of vitamin M deficiency in monkeys led Darby and his associates[5] of Vanderbilt University to test the therapeutic value of synthetic folic acid in 3 human cases. The 3 cases were of moderate severity and had persisted for from three to ten months. Each was characterized by sore mouth, diarrhea, weakness and loss of weight of 34 to 38 pounds (15 to 17 Kg.). There was increased fat in the stools (37 per cent of dried weight), macrocytic anemia and moderate leukopenia. There was impairment of absorption, as indicated by flat oral glucose and vitamin A tolerance curves. The clinical observations otherwise fulfilled all criteria generally accepted for the diagnosis of nontropical sprue.

These patients were given daily intramuscular injections of 15 mg. of synthetic folic acid as the sole therapeutic agent. By the fourth day symptoms of glossitis had disappeared. Definite hematologic improvement was noted by the ninth day, accompanied by regeneration of the lingual papillae, subsidence of the diarrhea and considerable gain in weight. Oral glucose and vitamin A tolerance curves became more nearly normal. The striking and rapid response of these patients led Darby to confirm the belief that synthetic folic acid is identical with, or closely allied to, the substance in liver extract which is effective in the treatment of sprue.

Detailed studies of the therapeutic value of folic acid in other types of anemia are reported in this issue by Spies[6] and his associates of the Hillman Hospital, Birmingham, Ala. These clinicians tested 45 clinical cases. They found that synthetic folic acid given either parenterally or orally is effective in producing significant hemopoietic response in persons with nutritional macrocytic anemia and with macrocytic anemia of pellagra, pernicious anemia, sprue or pregnancy. They found it ineffective, however, with aplastic anemia, iron deficiency anemia and anemia associated with leukemia. Whether or not folic acid is otherwise a full therapeutic substitute for liver extract they were unable to determine from their present clinical data.

THE ARMY'S PHYSICAL STANDARDS FOR INDUCTIONS

In the propaganda for a change in the nature of the practice of medicine, those who support government controlled medical care have emphasized chiefly up to now the number of men rejected by the armed forces as unfit for military service. Even President Truman, in sending his health message to Congress, dwelt considerably on these figures. Now the Army has suddenly lowered the physical standards for induction under the Selective Service; it will accept for induction men with the following physical defects previously listed as unqualified for military service:

> Lateral deviation of the spine from the midline of more than 1 inch and less than 2 inches; history of thyroidectomy for toxic goiter with complete absence of active manifestations for two years; hernia, inguinal, which has not descended into the scrotum; hernia, femoral; individuals with local paralyses such as those due to poliomyelitis or nonprogressive disease of the peripheral nerves of such degree that they disqualify for general military service but have not interfered with locomotion and have not prevented the individual from successfully following a useful vocation in civil life; stuttering or stammering of a degree disqualifying for general military service but which has not prevented the man from successfully following a useful vocation in civil life; mild neuroses; moderate transient psychoneurotic reaction, and mental deficiencies, mild in degree.

Thus the Army suddenly deprives these propagandists of one of their main arguments. The number of men rejected becomes considerably less; many men who would have been rejected under previous standards are now considered fit. THE JOURNAL has insisted again and again that the arguments of Senators Murray and Wagner and Congressman Dingell, who also emphasized the draft statistics, were without scientific foundation. Now the Army has proved them without scientific foundation. When a nation selects the highest standard of fitness for military service that any nation has ever established, people need not be surprised if the number of rejections is greater than those of nations whose standards are considerably lower. The public has little or no knowledge of the measuring stick that was used. Now the fact that the Army can change its measuring stick any time it wants to do so becomes clearly apparent.

Current Comment

NEUROLOGIC COMPLICATIONS OF MENINGOCOCCIC MENINGITIS

Neurologic sequels of meningococcic meningitis such as paralysis; deafness, deaf mutism or aphasic difficulties are frequent. The most common late complication is chronic hydrocephalus. Bailey[1] recently reported 4 cases in which neurologic complications followed the suppression of suppurative meningitis by sulfonamides or penicillin. In all the course of events was much the same: an acute purulent infection was controlled or cured by administration of sulfonamides or penicillin, but death or some serious neurologic disturbance developed. These therapeutic agents, Bailey says, do not exert any restraining influence on the fibroblasts which organize the exudate surrounding the meninges. The result is the formation of a dense scar through which the cerebrospinal fluid cannot circulate. The contraction of this scar tissue may constrict blood vessels and pathways essential to proper functioning of the nervous system. He does not suggest that these drugs be discarded in the treatment of suppurative leptomeningitis but offers a plea for early diagnosis and intensive therapy before a massive exudate has occurred. The prognosis in these cases is uncertain.

SLEEP DISTURBANCES OF CENTRAL ORIGIN

The evidence that lesions at the corticodiencephalic level are responsible for pathologic disturbances in sleep is scanty. Recently Davison and Demuth[1] studied 25 cases in which pathologic disturbances in the sleep mechanism was an important symptom. In 16 of these cases the hypothalamus was compressed and in all of them pathologic changes were found in the nerve cells of the hypothalamus. In 4 additional cases invasion of the hypothalamus with tumor cells had occurred, and in 1 there was partial destruction of the hypothalamus. Two cases showed compression of the hypothalamus with changes in the nerve cells; in 2 there was no compression of the hypothalamus or nerve cell changes. Compression or invasion of the basal ganglions existed in 16 cases in which there was also compression or invasion of the hypothalamus. Tumors were found in the suprasellar region in 3 cases, and these were included because of the involvement of the hypothalamus or its pathways. Increased intracranial pressure was found in 18 cases and was absent in 7. Diplopia, ptosis, weakness of ocular movements and impairment of conjugate deviation were found in 4 cases. Hypothermia was present in 4 cases. As a result of these and other investigations certain afferent and efferent connections concerned with sleep mechanisms were postulated: 1. The medial forebrain bundle (part of the hippocampohypothalamic tract, running between the ventromedial olfactory correlation areas of the cortex and the preoptic and hypothalamic areas; there is some evidence for the passage of a septohypothalamic tract via this bundle. 2. Corticohypothalamic fibers, via the fornix, arising in the hippocampus and ending in the medial and lateral mamillary nuclei and in the adjacent rostral portion of the tuber cinereum. 3. Inferior thalamic peduncle; fibers connecting the cortex and the hypothalamus via this peduncle probably originate in the frontal, temporal and hippocampal convolutions. 4. Hypothalamocortical fibers; such connections have not been demonstrated, but their existence is probable.

NORTH CAROLINA'S PROPOSAL FOR HOSPITAL AND MEDICAL CARE

In a handsome brochure addressed to the people of North Carolina,[1] a commission composed of physicians and leading citizens from other walks of life, including some representatives of the clergy, issue a "statement and appeal to the people of the state." The appeal is based on a number of committee recommendations concerning the proposal for North Carolina of a four year medical school, the meeting of hospital and medical needs of urban and industrial populations, the hospital and medical care of rural populations and the special needs of the Negro population. Each of these areas has been studied by a special subcommittee, and in addition studies were made of hospital and medical programs in other states. The commission concludes that North Carolina has three primary needs: more doctors, more hospitals and more insurance. A convincing case is made in the brochure for the need for more doctors and better distribution. Significant is endorsement of cooperation between North Carolina and adjoining states in establishing a regional medical school for Negroes. The commission also points out convincingly the need for hospitals. Support is given to the Blue Cross hospitalization plan, and the commission expresses its belief that every citizen needs to realize that it is just as important to have insurance against sickness disasters as against fire disasters.

ERYTHROBLASTOSIS FETALIS

Nine cases of erythroblastosis fetalis have been reported by Polayes and Ohlbaum.[1] In each instance the mother belonged to blood group O and the infant belonged to blood group A. The mother's serum showed abnormally high anti-A agglutinin titers. The Rh factor and the Hr antigen were eliminated as possible immunizing antigens in each case. Most of the infants had a relatively mild form of hemolytic disease of the newborn, but 2 of the 9 infants died. Postmortem examination showed the anatomic changes characteristic of erythroblastosis fetalis. The authors believe that erythroblastosis fetalis may result from isoimmunization with the A and possibly the B antigen by a mechanism similar to that already established for the Rh factor.

MEDICINE AND THE WAR

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

REFUSAL TO DEFER PREMEDICAL STUDENTS CONFIRMED

In a letter to Dr. Frank H. Lahey, chairman of the Procurement and Assignment Service, the Office of War Mobilization and Reconversion again refuses to take any action to defer premedical students. The letter follows:

OFFICE OF WAR MOBILIZATION
AND RECONVERSION
Washington, D. C.

Jan. 29, 1946.

Office of the Director

Dear Dr. Lahey:

This will acknowledge your letter of January 15 and the attached statement supporting Dr. Barton's oral presentation of the case for deferring premedical and predental students. Copies of your statement were supplied to all members of the Inter-Agency Committee on Manpower Shortages. After full consideration of the facts which you presented and of the current and prospective manpower situation, we have decided that we cannot ask that special deferment consideration be extended to this group at this time.

This decision is based upon the following considerations:

1. The Army is now in urgent need of replacements for men who have served for long periods. The bulk of all replacements must come from the 18 year old group. In the face of this need, we do not feel that any group of men becoming 18 years of age can be deferred at this particular time.

2. We anticipate that the number of veterans entering various classes of premedical and predental school during the coming year and the following years will be far in excess of the numbers that would be expected if enrolments in the fall term of 1945 were extended as a basis for estimates. Your estimates of premedical and predental students who will be ready to enter medical or dental school during and after 1948 therefore appear low.

3. While there may be fewer doctors and dentists than the nation actually needs during the coming years, this is also true of a number of other professional fields equally essential to the national welfare. We have, for example, recently declined to urge special deferment consideration for students in scientific and engineering fields who have completed less than three years of work. Our policy is to urge special deferment consideration only for advanced students. Premedical and predental students do not fall within this category.

4. In view of the long average periods of active work in professional fields, and the possibility of expansion in medical education, we do not feel that failure to maintain premedical and predental training at capacity for a short period will significantly reduce the number of doctors and dentists available in the coming years.

We shall continue to balance the manpower needs of the armed forces against requirements for the civilian economy. If extension of deferments appears possible in the future, the status of premedical and predental students will be reviewed again.

Sincerely yours,
J. DONALD KINGSLEY
Director for Manpower
and
Chairman, Inter-Agency
Committee on Manpower Shortages.

ARMY

NOMINATE ASSISTANTS TO THE SURGEON GENERAL

The President recently recommended to the Senate the nominations of Brig. Gens. George S. Beach Jr., Raymond W. Bliss and Edward A. Noyes to be assistants to the Surgeon General with the rank of brigadier general for a term of four years.

General Beach has been commanding general of Brooke General Hospital, Fort Sam Houston, Texas, since July 1941. General Bliss, recently appointed Deputy Surgeon General in addition to his duties as Assistant Surgeon General and Chief of Operations Service, has been with the Army since 1912. General Noyes, surgeon of the Fifth Service Command, Fort Hayes, Ohio, since 1944, was formerly commanding general of Cushing General Hospital at Framingham, Mass. He accepted a Regular Army commission in 1916.

APPOINTED COMMANDING OFFICER OF ENLISTED PERSONNEL

Major Edward G. Streidl, formerly executive officer of the Medical Field Service School, Carlisle Barracks, Pa., was recently appointed commanding officer of the enlisted personnel at the Army Medical Center, Washington, D. C. Major Streidl entered the army in 1930.

NUMBER OF MEDICAL OFFICERS RELEASED

The Office of the Surgeon General recently stated that, up to January 26, 23,779 medical officers and 32,395 nurses had been released from service.

ARMY AWARDS AND COMMENDATIONS

Brigadier General Stanhope Bayne-Jones

Brig. Gen. Stanhope Bayne-Jones, Deputy Chief of the Preventive Medicine Service, Office of the Surgeon General, was recently awarded the Distinguished Service Medal for his outstanding "contribution to the maintenance of health within the Army. As administrator of the Epidemiological Board, he directed the extension, administration and military application of the world-wide research and control program conducted by this board and its ten commissions."

General Bayne-Jones graduated from Johns Hopkins University School of Medicine, Baltimore, in 1914. He entered the Medical Reserve Corps in 1915 and served throughout World War I. From 1917 to 1918 he served with the British Expeditionary Forces in France and Italy and later with the AEF in France and Germany, and has been decorated with the British Military Cross, the French Croix de Guerre and the Silver Star with two Oak Leaf Clusters.

Prior to being ordered to active duty in 1942, General Bayne-Jones was professor of bacteriology at Yale University and had held the position of dean of the School of Medicine at that university.

Colonel Hirsh Julian Frachtman

Col. Hirsh Julian Frachtman, formerly of Houston, Texas, was recently awarded the Bronze Star for meritorious service as Chief of Medical Service of the 22d Station Hospital in the Central Pacific Base Command. The citation accompanying the award read: "For meritorious service in connection with military operations against the enemy from Feb. 10, 1944 to July 1, 1945. As chief of Medical Service, 22d Station Hospital, with an acute shortage of personnel and with heavy patient loads, Colonel Frachtman organized and developed the medical service to a peak of operating efficiency. Through his tireless devotion to duty, diligence, ingenuity and superior planning, he contributed materially to the successful operation of the 22d Station Hospital. The outstanding performance of duty displayed by Colonel Frachtman reflects great credit on himself and the military service." Dr. Frachtman graduated from the University of Texas Medical Branch, Galveston, in 1937 and entered the service Nov. 6, 1940.

Lieutenant Colonel Albert B. Sabin

Lieut. Col. Albert B. Sabin of Cincinnati was recently awarded the Legion of Merit "for exceptionally meritorious conduct in the performance of outstanding service in connection with the investigation and control of sandfly fever, dengue fever and Japanese B encephalitis." Dr. Sabin graduated from the New York University College of Medicine, New York, in 1931 and entered the service April 21, 1943.

Lieutenant Colonel Kerwin Armand Fischer

The Legion of Merit was recently presented to Dr. K. Armand Fischer, Louisville, Ky., for his work as chief of the orthopedic section of Billings General Hospital at Indianapolis. As a lieutenant colonel, Dr. Fischer "performed a tremendous number of difficult major orthopedic operations" and trained young officers in orthopedic surgery, saving "many days of hospitalization" for patients at Billings. Dr. Fischer graduated from the University of Louisville School of Medicine in 1926 and entered the service July 8, 1942.

Colonel John H. Talbott

Col. John H. Talbott, commanding officer and director of research of the Quartermaster Climatic Research Laboratory, Lawrence, Mass., was recently awarded the Legion of Merit for his "professional skill, inspirational leadership and comprehensive understanding of the problems of thermoconductivity which enabled him to contribute to the welfare and morale of every combat soldier." Dr. Talbott graduated from Harvard Medical School, Boston, in 1929 and entered the service May 17, 1942.

Colonel Franklin G. Ebaugh

Col. Franklin G. Ebaugh of Denver was recently awarded the Legion of Merit for "organizing the psychiatric services in various general and regional hospitals" in the Eighth Service Command, where he was Neuropsychiatric Consultant. "Colonel Ebaugh also developed an outstanding medical educational program which coordinated the neuropsychiatric field with the other phases of the medical services." Dr. Ebaugh graduated from Johns Hopkins University School of Medicine, Baltimore, in 1919 and entered the service Sept. 15, 1942.

MISCELLANEOUS

UNRRA NEWS

Outfit Twenty-Eight Hospitals in Europe

The United Nations Relief and Rehabilitation Administration is outfitting twenty-eight hospitals, totaling more than 26,000 beds, in three European countries. The hospital outfits have been purchased from army surpluses in the United Kingdom and on the European continent and are being trucked or shipped by sea to Czechoslovakia, Poland and Yugoslavia. The outfits include surgical instruments, beds, blankets, account books and case record charts.

In addition to their work in obtaining the larger units, the UNRRA medical supply men are continuing to comb military surplus stock to obtain equipment for approximately forty-five convalescence centers which will be able to handle less serious cases of illness and those which are enabled after treatment to be moved out of the hospitals to make way for other serious cases.

Public Health Activities in Poland

After a tour of inspection of UNRRA'S public health activities in Poland Dr. W. A. Sawyer, director of health, UNRRA headquarters, reported that he visited Warsaw, Lublin, Cracow, Breslau, Posen and Lodz. Most of his time was spent in consultation with Poland's public health officials and the UNRRA staff and in visiting hospitals, health centers and medical schools. Lectures on the discoveries and new methods in public health and medicine were given in all these cities as the doctors had been isolated for six years from the advances in medicine in the outside world.

In his report Dr. Sawyer stated that the picture presented by Poland today is that of a country recovering from a degree of physical destruction and personal suffering hard to imagine and impossible to describe. The people lack almost everything —food, shelter, clothing—everything except courage and the will to pull themselves up again by their bootstraps. The spirit of Poland is as wonderful as the conditions are appalling.

The most serious health problem is that of preventing the spread of typhoid. Peacetime preventive measures such as chlorinating water supplies have been seriously affected by the destruction of war. The problem of control is aggravated by the tremendous movements of population both within the country and from without. Diphtheria too is giving the health officials great concern. Tuberculosis is widespread as an inevitable result of food shortages, lack of adequate shelter and similar hardships resulting from the war.

Dr. Sawyer further stated that he was greatly impressed by the earnestness and competence of Poland's health officials both in the central Ministry of Health and among health officials in the field. Our relations with them are most satisfactory, and they are doing everything in their power to put the supplies provided by UNRRA to good use among those in greatest need. Although the winter months ahead present critical disease problems, the introduction of supplies, of transportation and of professional health consultants is probably early enough to enable Poland's effective Ministry of Health to cope with the difficulties. UNRRA'S Health Division will do its utmost to make a successful campaign possible.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

INDIANA

Indianapolis City Hospital, Indianapolis. Capacity, 739; admissions, 10,231. Dr. Charles W. Myers, Superintendent (resident—psychiatry).

KANSAS

University of Kansas Hospital, Kansas City. Capacity, 400; admissions, 8,247. Dr. T. G. Orr (resident—anesthesia).

MASSACHUSETTS

Lowell General Hospital, Lowell. Capacity, 188; admissions, 3,068. Miss Carrie B. Knowlton, R.N., Superintendent (2 interns, April 1).

MISSOURI

St. Joseph's Hospital, St. Joseph. Capacity, 150; admissions, 3,623. Sister Catherine, R.N., Administrator (interns, residents—mixed service).

OHIO

Lakewood Hospital, Lakewood. Capacity, 157; admissions, 4,677. Dr. R. B. Crawford, Superintendent (interns, residents—mixed service).

PENNSYLVANIA

Women's Homeopathic Hospital, Philadelphia. Capacity, 210; admissions, 3,765. Miss Mary A. Smith, R.N., Superintendent (interns, April 1).

VIRGINIA

Elizabeth Buxton Hospital, Newport News. Capacity, 181; admissions, 6,947. Dr. Russell Buxton, Superintendent (residents—mixed service).

WASHINGTON

Providence Hospital, Seattle. Capacity, 434; admissions, 11,810. Sister Bernardine, R.N., Superintendent (4 interns, July 1).

THE PUBLIC RELATIONS OF AMERICAN MEDICINE

Morris Fishbein, M.D.
Editor, The Journal of the American Medical Association
CHICAGO

Centuries ago the profession of medicine was little concerned with public opinion. Medical knowledge was concealed in mystery. Latin was used by physicians in their discussions and in their prescriptions. Patients were never admitted into the inner sanctum. Medical books were written in a language difficult to understand. The nomenclature of disease, of drugs and of operative procedure was concocted to preserve secrecy. The medicine of those days had little to give for the public good compared to what modern medicine has to offer. Perhaps concealment of the limitations of medical knowledge was desirable for the maintenance of public respect. Often people admire most that of which they know least.

Medicine was not, however, the only human undertaking that kept from people generally information of its activities. Governments have from time immemorial kept from the people whom they govern the information that the people have needed to evaluate accurately what their governments are doing for them. Great industries have often kept from the consumers of their products and even from the stockholders the intimate details of their activities. The present century, however, has seen a striking change in attitudes. Leaders now realize that public good will can do much toward success in achieving well warranted objectives. The development and maintenance of good will is the fundamental objective of the profession of public relations. However, experience has demonstrated through experimental evidence and through well documented case histories that public relations technic, like any well conceived therapy for any disease that occurs to the human body, is limited in its success by many uncontrollable factors. The legendary case history in the field of public relations is the story of the change in public attitude toward John D. Rockefeller. The early days of the development of Standard Oil and particularly its relations with labor brought upon Mr. Rockefeller a good deal of public condemnation. The pioneer public relations expert Mr. Ivy Lee was summoned. According to legend, Mr. Ivy Lee stated that it would be difficult indeed to create good will for the John D. Rockefeller whom the public had in mind but that it might be possible to create a different John D. Rockefeller who would easily earn public commendation. Thus came the great philanthropist to whom we owe the Rockefeller Foundation, the International Health Board, the University of Chicago and similar agencies. The transition period is still in the minds of many whose period is contemporaneous with that of Standard Oil. The success of Goebbels and Mussolini in swinging entire nations to unification behind beliefs that were essentially unsound might be cited as proof that public relations in a totalitarian nation can sell even an unsound proposal. However, the history of Germany and Italy proves that an unjust or unfair proposal cannot be sold indefinitely. Sooner or later the public becomes aware of the inefficiency or the inadequacy of the product. Thereafter no amount of public relations effort can be successful in maintaining public confidence. In a democracy such as ours not even the government can monopolize a public relations effort. The public relations activities of industries, professional associations, nonprofit philanthropies and governmental agencies are competitive for the good opinion of the people.

REPORT ON PUBLIC RELATIONS

The application of these principles to the relations of American medicine to the medical profession and to the people was carefully considered at a conference called by the Council on Medical Service of the American Medical Association at a meeting in November 1945. From that conference came a report which was presented to the House of Delegates at its meeting in December and which received the approval of the House of Delegates. The report of the special committee of the conference on public relations indicated that two different public relations efforts are essential for American medicine. One is concerned with the members of the medical profession and with various medical organizations; the other is concerned with the relations of medicine to the public.

PUBLIC RELATIONS OF MEDICINE FOR THE PHYSICIAN

Thorough education of the medical profession is a necessary preliminary to the establishment of efficient public relations with the public. It is difficult to get physicians to inform themselves concerning current problems in social medicine and in medical economics. Many physicians will not acquire the necessary information even though it is given to them through national, state or local medical publications. An informed medical profession is, however, essential to unification of effort and to any attempt to acquaint the public with the ideals that underlie our objectives.

By the nature of medical organization in the United States the majority of effort to reach the individual physician with necessary information must be made by the county and state medical societies. The Journal of the American Medical Association is the most widely read of all medical publications. But even in The Journal many readers carefully avoid the proceedings and minutes of official committees and boards and councils. I have watched for thirty years various attempts to induce the American physician to inform himself fully on medical economic matters and to participate fully in the efforts necessary to reach the public and the Congress. The American Medical Association sent a special periodical devoted wholly to medical economics without charge to every Fellow of the American Medical Association. It was not read by enough regularly interested readers to make its maintenance desirable. The Board of Trustees therefore discontinued the publication of the *Bulletin* and restored the discussions of medical economics and medical legislation to the pages of The Journal. The reasons underlying the disinterest of great numbers of the medical profession in these problems that are essential to their welfare are probably the same as underlie the disinterest of a great number of citizens in similar problems that concern them.

The advancement of medical science with the increase in specialization, the formation of great numbers of specialistic medical societies, the installation of the compulsory hospital conferences, the insistence on long internships and residencies which prolong extensively the preparation of the doctor, so that his actual years of practical work are limited, have all contributed to lessening the opportunity of the individual physician to participate fully in the work of his county and state medical societies. This attention has been turned more and more to the strictly scientific aspects of his practice. Perhaps a necessary stimulus to secure his interest in medical economic affairs would be an immediate and violent attack on his pocketbook. The theoretical possibility of such an attack invoked in the establishment of a compulsory sickness insurance system does not particularly disturb him. He appears confident that his organization will look after his interest. Moreover, it is evident, and indeed the promoters of socialized medicine do not hesitate to promise, possibly with tongue in cheek, that under a socialized system the one third of the profession who have the lowest incomes would probably benefit materially.

An intensification of interest of the majority of the medical profession, and particularly of leaders in the various specialties, in the social and economic aspects of medical service is exceedingly desirable. Much of our public relations effort must be directed at the earliest possible moment to securing just such an interest—to securing, in fact, an active participation beyond even the subscription of funds. Every physician should have full knowledge of what is involved in current legislative proposals and should participate fully in the effort to extend such information to the public.

Careful consideration was given by the Board of Trustees of the American Medical Association some years ago to the question of making certain that essential information reached at least the physicians who are primarily responsible for the conduct of the public affairs of American medicine. As a first step in this direction, even before the establishment of the Council on Medical Service, the Board of Trustees developed a letter to be sent regularly without charge to such physicians. In the compilation of the mailing list it was discovered that the number of such men constitutes only a small percentage of the total number of physicians in the United States. Approximately 190,000 physicians are licensed to practice medicine, and of these about 155,000 are actually in practice. Membership in the American Medical Association includes well over 125,000 physicians. The Fellowship in the Association approximates 70,000 physicians. A careful listing of the physicians in the United States who carry on most of the public work of medicine yielded nearly 3,000 names. These are the officers (including the councils) of the state medical societies, the members of the House of Delegates, the officers of national medical associations not rigidly scientific in their objectives and the editors of state medical journals and of important county medical society bulletins. News letters are more extensively read than any other type of informational material thus far developed. More recently the Council on Medical Service has initiated and carried on the news bulletins which it now sends both from Washington and from Chicago to interested and active leaders.

Significant also are the regional conferences conducted by the Council on Medical Service as a means of enlightening medical workers in public affairs. Even though these regional conferences are thrown open to attendance by any member of the medical profession, the attendance seems to be voluntarily and narrowly limited by the will to work of those in the area served.

In choosing the title for this address I carefully made it "The Public Relations of American Medicine" rather than "The Public Relations of the American Medical Association." The American physician has become an important figure in the social and economic life of our country. He does not obtain his information in public affairs and in the field of medical economics solely from the publications of his own organizations. Much of what he hears and reads comes to him through agencies that are not the official agencies of the medical profession. Exactly as he was compelled in a previous era to make his own distinction in the authenticity of scientific data presented in a variety of periodicals, of claims for therapeutic agents offered in original allegedly scientific contributions and in advertising of physical devices, of foods and of educational institutions, so must he now depend on his own ability to evaluate evidence in the field of medical economics. In an earlier day the proprietary medicine manufacturers, the promoters of peculiar physical apparatus, the owners of some 165 medical colleges were the purveyors of highly questionable data which the physician himself had to evaluate. Then came the Councils on Pharmacy and Chemistry, on Medical Education and Hospitals, on Foods and Nutrition and on Physical Medicine, and later the Council on Industrial Health, to study new drugs, new devices and new proposals to assemble all relevant data and to evaluate them and to place on those which seemed to merit approval an indication of their acceptance. In the field of medical economics there was not, until the establishment of the Council on Medical Service, any authoritative agency that could make such an evaluation. The Bureau of Medical Economics of the American Medical Association was charged with assembling data concerning all matters in the field of economics in medicine, and it published during the period of its greatest efficiency before the war, when it was adequately served with personnel, a vast amount of important and reliable data.

DIAGNOSING THE PROBLEM

The accumulation and assembling of sound factual data is fundamental to any public relations effort in the field of medicine or in any other field. In understanding the public relations effort of medicine, an adequate diagnosis of the problem is essential.

Mr. Carl Byoir, well known expert in public relations, calls attention to the fact that current headlines documenting the swing of nation after nation to the left are a warning signal. "Obviously," he says, "capitalism as a way of business and a way of life can survive in our democracy only if enough people are convinced that their best interests are served by it. . . . In the final analysis, public relations is long-range planning." By promoting interest in the medical profession with the general public, public relations will pave the way for better relationships with future employees who will be recruited from the public, with the patients who are the public and with government officials who not only are part of the public but who like to feel that they represent the public's opinion.

The first task of a public relations effort is to determine the public whose favorable opinion is to be sought and to plan a public relations program directed to that public. What do the people who are the patients of the physicians, and the legislators who are not only patients but who also represent people generally, think about medicine? Do they have opinions that are unfavorable to the medical profession? After scientific research into such opinions have revealed their nature and has indicated practices that are unsatisfactory to the people, we must determine whether or not it is possible to change such practices and thereby to change opinion. If the practices should not be changed, the public must be convinced of their necessity.

In the field of medicine it has become clear, both in the United States and in Great Britain, as has already been well established, that the relations of the individual physician to the individual patient are on a substantially sound basis. The public in general does not express resentment against the individual physician. There are, of course, instances in some communities in the United States in which some physicians have been tactless or careless or outright greedy in assessing costs for medical service to their patients. When in any community the general practice of medicine or of any other necessity of human life becomes so costly that it is not generally available to the vast majority of the people, resentment is bound to develop among the people against the purveyor of either a commodity or a service. In the United States as a whole the high standard of living and the average income of the worker have been sufficient to permit him, in the vast majority of cases, to meet the costs of medical care. The difficulty arises, however, as innumerable economists and social service workers have pointed out, when catastrophic illness strikes as an emergency. Even most of our wage earners in the higher levels are often unprepared for a major surgical operation, for a considerable stay in the hospital, for a serious siege of pneumonia or gastric ulcer or for a chronic psychiatric disturbance.

PUBLIC RELATIONS ACTIVITIES FOR THE PUBLIC

The American people do not question the quality of medical service available in the United States. The medical profession has utilized the press, motion pictures, exhibits, the radio and every other means of dissemination of information to educate the Americen people as to the advances of medical science Nothing even approximating this educational effort has been accomplished in any other country in the world. In this work the leadership of the American Medical Association is acknowledged and is recognized by innumerable agencies. Press associations like the Asociated Press, the United Press and the International News Service cooperate fully. The broadcasting chains (particularly the National Broadcasting Company, over whose channels for almost a decade there have gone regularly magnificent programs of health education) have published their recognition of merit. Exhibits disseminated by the Bureau of Exhibits are requested far beyond our ability to supply them. Hundreds of thousands (if not millions) of letters have gone directly to the public from the Bureau of Health Education, the Bureau of Investigation and the various Councils of the Association and indicate public confidence in the information provided. The extension of scientific contributions from all the periodicals of the Association to the press and the radio, the efficient arrangements for extending the scientific advances reported at various scientific sessions of the Association, which have begun to be imitated by other organizations in the field of science, the lectures by the members of the headquarters staff, are additional means that are extensively employed. *Hygeia* is now recognized as the most successful exclusively health periodical ever developed in the United States; today it is more quoted by newspapers, digest magazines and other publications than any other periodical in this country. In all of these ways the American Medical Association has demonstrated its ability to inform the public about the advancement of medical science and the services that physicians can render. Furthermore, through cooperative efforts with the National Education Association, the American Association for Health, Physical Education and Recreation and many similar bodies, health education is now being definitely integrated into the curriculum of our schools. Experts in the field of public relations who have been informed of these efforts and whose advice has been sought are unanimous in their statement that these activities constitute one of the most efficient performances in the field of public relations undertaken by any profit or nonprofit group in our country.

Of course the American Medical Association has not been alone in this effort to educate our people regarding medicine and health. The United States Public Health Service, many of the state medical societies, many public health officials and public health agencies and the great philanthropies, such as the American Cancer Society, the National Tuberculosis Association and the National Foundation for Infantile Paralysis, have contributed notably. Incidentally, all these agencies secure much source material from the American Medical Association. A survey of public opinion reveals that there is general public acceptance of the American Medical Association and its policies as far as concerns scientific progress, health education and protection of the public against inferior medicine and quackery. In one survey a majority of persons who knew of the American Medical Association stated that it was an organization primarily concerned with the advancement of medical science and with the protection of the public against fraudulent medicine.

THE PRIMARY PROBLEM IN MEDICAL PUBLIC RELATIONS

What, then, is the primary problem in public relations of the medical profession in the United States today and how is that problem being solved? When Bismarck introduced social security in Germany in 1883 there were few repercussions in the United States. Our concern with the problem began in 1911 after Lloyd George had converted Great Britain to national sickness insurance as a means of defeating the Labour Party in a British political controversy. The problem came prominently to the attention of the House of Delegates in the years from 1914 to 1916 and a resolution was adopted urging the American Medical Association to act in behalf of molding legislation for compulsory sickness insurance. A committee was appointed to study the problem, and a series of pamphlets, largely favorable to compulsory sickness insurance, was published under the auspices of the Council on Health and Public Instruction of the American Medical Association. However, when the dangers to the public interest of such a system became evident, medical opinion crystallized against state medicine, socialized medicine and compulsory sickness insurance. Medical opinion in the United States has been firmly opposed to such systems of medical care since that time. The majority of medical opinion opposed to compulsory sickness insurance has gained in strength and vigor as the years have passed.

In 1932 the Committee on the Costs of Medical Care offered its proposals for change in the nature of the practice of medicine. These too were officially opposed by the medical profession, which at that time also opposed voluntary sickness insurance as well as voluntary hospitalization insurance. Perhaps a word is necessary now to indicate the reason for that attitude. The medical profession is scientifically trained. Before any new method of treatment is accepted, the value must be demonstrated and the safety of the method must be assured. Medicine as a profession demands equally that social experiments in the field of medical practice prove their value and their safety before they are acceptable and before they are extended to the public. People in general must depend on the physician to protect them from harm in the use of new and untried remedies. People must depend on the medical profession equally to protect them against social experiments in the administration of medical service which may do more harm than good. Until actuarial data became available sufficient to warrant the calculation of risk, it would have been folly to propose hospitalization insurance for general adoption throughout the United States. The history of innumerable hospitalization plans has proved the necessity for careful trial on a small scale of any plan before it is accepted for general adoption. Some of the hospitalization plans which are today among the leaders in membership and in efficient service passed through periods of trial in which their fate hung in the balance and in which the prognosis was grave. In the practice of hospitalization insurance questions still arise as to relationships between the hospitals and the medical profession. The methods of remuneration of physicians, the responsibility of the hospital to the patient, the responsibility of the physician to the patient and the relationship of some technical practices to professional practice still present unsolved problems. Every one of these demands careful consideration not only for the good of the individual patient but also for the ultimate effect of the decision on the advancement of medical science.

The problems in the field of voluntary sickness insurance, either by private insurance companies or by nonprofit voluntary mutual insurance companies, are even more numerous and concern more seriously the advancement of medical science, the quality of medical service and the relationship between doctor and patient. Nevertheless many of these problems are now being solved by the standard technic of trial and error, with correction of error when it is determined. This is the scientific method first propounded by Hippocrates and recognized by philosophers and statesmen as one of the greatest contributions of all time to human civilization.

The American Medical Association is frequently accused by the revolutionists in the field of medical care of fighting a rear guard action against the proponents of changes in the nature of medical practice. The history of medicine contains enough examples of the need of scientific study of new technics before general acceptance to warrant the delaying tactics that have been a feature of the policies adopted by the House of Delegates since 1932. These policies will yield a system of medical care for the American people consistent with democratic government and capable of providing under insurance principles a high quality of medical service. A too ready acceptance of half-baked financially unsound proposals in the field of prepayment plans for medical care would have yielded, as it has already in some other countries, notably New Zealand, only a series of disastrous failures. These would have led inevitably and soon to the taking over by the government of the complete sickness insurance program. This has been the history of sickness insurance up to this time. There is no reason to believe that a repetition of the poorly considered programs that developed in other countries would have led in this country to anything other than a governmentally owned system of medical practice and a deterioration in quality of service.

The present problem of public relations in American medicine in this country is to convince the American people that a voluntary sickness insurance system developed with features peculiar to the American way of life is better for the American people than a federally controlled compulsory sickness insurance system. In the attempt to educate the people regarding this problem and to convince them of the soundness of the point of view of the medical profession, many public relations technics have been employed. These have included, on the part of the American Medical Association, the presentation of data developed by its own Bureau of Medical Economics, policies adopted by its House of Delegates and widely circulated through the press, public debates in which many officials of the American Medical Association have participated, and the use of the press, the radio, periodicals, public addresses, motion pictures and every other medium of public expression. Many of the state medical associations have carried on independent efforts which have been highly efficient in their performance. Some groups of states have participated in such activities. A considerable number of states, however, have failed to be especially active in this regard.

By the American system of government, the ultimate decision must rest with the Congress of the United States. In the history of the American Medical Association now being prepared for the one hundredth anniversary in 1947 some of the record of the activities related to the Congress will be made available. Intelligent men learn from experinece. Previous experience has guided what is now being done. Congressmen are more and better convinced by hearing the views of their own constituents than by printed matter or even by personal interviews from representatives of national agencies. The American Medical Association and other national agencies have made certain that our representatives in the Senate and in the House are fully informed concerning the fundamental data related to medical service and the professional aspects of medical care. They look to the medical profession for authoritative opinions on the medical service aspects of sickness care. They do not look to the medical profession for either data, opinion or argument concerning the costs of such a program, the methods of compensation or the rights of the government in relationship to the provision of funds. Incidentally, just how many measures inimical to the medical profession or the advancement of medical science have ever passed the Congress? For more than thirty years a compulsory sickness insurance bill has been introduced at every Congressional session. Thus far not one has ever reached the likelihood of favorable consideration.

The headquarters of the American Medical Association has established relationships with most of the leading periodicals of the United States, with the press and the press associations, with the radio chains and with every other medium of public expression sufficient to make certain that all of these are available for extending to the people the point of view of American medicine. In these efforts many of the state medical associations and a good many county medical societies participated fully. Certainly the periodicals of the state medical associations have been liberal in the space devoted to such discussions and have in many instances efficiently extended their discussions to the general press in their own states. The American Medical Association has not purchased either radio time or advertising space for the expression of its point of view. The Board of Trustees apparently has not felt that such an action was consistent with the nature of the Association or with the policies advocated by the House of Delegates. Nevertheless this aspect of extension of medical opinion to the public has not been neglected. Recently other agencies have entered the field to meet this need in behalf of American medicine and to carry on a public relations effort sufficient in scope and influence to meet modern concepts.

ORGANIZATIONS ACTIVE IN MEDICAL PUBLIC RELATIONS

The National Physicians Committee has supported the policies of the House of Delegates and has, by a variety of technics, extended its point of view to the American people.

Among the membership of the American Medical Association is a small percentage of physicians who do not agree with the policies of the House of Delegates regarding social aspects of the practice of medicine. Such groups as the Physicians Forum, the Committee of Physicians and the American Association of Physicians and Surgeons from time to time express themselves on such subjects. They compete through press releases or radio talks and in various other ways for public support with the official agencies of American medicine. Naturally their views receive wide publicity in the part of the press favorable to such views.

The Physicians Forum includes in its membership something under 2,000 names, with perhaps 50 active participants in its work. This is purely an estimate, although it is based on communications which have been received from Dr. Ernst Boas, who spearheads this effort in favor of socialized medicine. The Committee of Physicians once included some 400 names and it may now include something under 1,000. Its active body includes not more than 15 and probably 2, namely John Peters and Allen Butler, who do 99 per cent of its work and make its opinions. The American Association of Physicians and Surgeons has, according to fairly well substantiated rumor, received $10 from each of 6,000 physicians who have subscribed to its principles. Just what it has accomplished other than to state its objectives and to get them out in the press is not clearly apparent. This group, however, proposes that the physicians of the United States strike against the sick public in case the government of the United States should establish compulsory sickness insurance. Such an action would be contrary to all of the tradition of medical science covering the responsibility of the physician to the sick. No official body of the American Medical Association has ever ventured even the thought that physicians would neglect to minister to the sick as evidence of their opposition to the law of the nation.

The National Physicians Committee has been most effective of all the organizations striving to mold public and legislative opinion in the field of medical care. Its efforts have been repeatedly endorsed by the House of Delegates of the American Medical Association. This agency has used syndicated newspaper publicity and editorial opinion, newspaper advertising, pamphlets, radio, direct-by-mail solicitation, education and every other technic of public relations in its work. Currently some thousands of representatives of medical industries are encouraging every one whom they meet or interview to communicate directly with the Congress expressing opposition to the compulsory sickness insurance feature of the National Health Program and to the Wagner-Murray-Dingell bill. In many communities joint action by physicians and medical industries has been stimulated to the insertion of advertising in the press, the use of local radio and other public relations work against state medicine. From twelve to fifteen million pamphlets were circulated in the attack on the previous Wagner-Murray-Dingell bill, which passed into innocuous desuetude, and many millions of pamphlets are now being circulated through drug stores, supply houses, hospitals and other medical agencies. Through this group also physicians are being educated as to the details of the proposed legislation, and they will be encouraged to make direct contact with legislators from their own states to make certain that the legislators are fully informed. The budget approximates several hundred thousand dollars and the funds are, as nearly as I can determine, efficiently and economically used. The medical profession owes a great debt of gratitude to the distinguished physicians who serve as the directing board of the National Physicians Committee and to the staff who carry out so effectively the policies that this board establishes.

Recently the Board of Trustees of the American Medical Association has employed competent public relations counsel to survey the activities of the American Medical Association in the field of public relations. Such counsel will evaluate the work, determine which activities are yielding effective results and which perhaps are failing, determine whether other activities should be undertaken and recommend for the American Medical Association a complete program in public relations. This action by the Board of Trustees is in accord with a modern trend toward recognition of the part that public relations plays in the conduct of any industry or public agency. The public relations activities of the American Medical Association are in process of evolution. The various councils, bureaus and committees of the Association were initiated in response to recognition by the House of Delegates of certain needs, and they have grown and evolved to fill the need.

Public relations is still a new profession. Many of its technics are still highly experimental if not controversial. One authority urges participation in public debates as a stimulant of interest; another asserts that public debate tends only to confuse the people and never convinces any one. On social proposals an organization like the American Medical Association may come into direct competition with the government for public favor. On some proposals it may enhance the government's efforts. When the President of the United States alines himself with a social point of view that is opposed by a private agency, that point of view achieves additional weight. Nevertheless in the past other presidents have thrown their weight in behalf of social or economic measures which were opposed both by individual agencies and eventually by the Congress and which, obviously, never became the law of the nation. The present efforts on the part of the federal government to impose compulsory sickness insurance on the American people and on the medical profession is a political procedure made without adequate study and without regard to scientific factors fundamental to the health of the American people. Thomas L. Cotton, a public relations expert in the field of social research, has said "Few American business men welcome increased regulation of their operations by government. Freedom of initiative is circumscribed and the cost of operations usually increased. The opposition of business men to such threatening proposals has not always been well timed or wisely conceived. Oftentimes these regulatory measures for alleged social gains originate in some social agency or civic betterment group. Usually there is a long period of incubation before these ideas are hatched into legislation. During that formative period business men pay little attention to the matter. Of a sudden, legislation is introduced which is so idealistic that business could not live under it and the public relations man finds himself facing a serious problem." Mr. Cotton was concerned with the problem of small loans; yet that paragraph might just as well have been written about socialized medicine.

Today American medicine is in a strong position for the maintenance of a high quality of medical service, for progress against disease, for the development of an American system of medical care which will be free from governmental domination. Many important legislators, probably a majority of legislators, feel that the medical profession must be given its opportunity to meet the challenge before government intervenes. The conference on public relations of the Council on Medical Service concluded: "Antagonism of some elements of the public toward medical organizations seems to rest on the basis that opponents of organized medicine offer a specific program which promises complete medical care on what seems to be a relatively small financial outlay, whereas the medical profession has not yet come forward with a specific program for the extension of medical service on a nationwide basis with a system of payment easily available and sufficiently attractive to insure early enrolment of a large proportion of the public. The task of public relations would be rendered much easier if those concerned could be put in possession of a constructive program which they could promote to the public rather than in a position of continuous defense against programs coming from other sources."

The House of Delegates adopted a resolution recommending that the Board of Trustees and the Council on Medical Service and Public Relations proceed as promptly as possible with the development of a specific national health program. That program is near to completion and should soon be announced to the medical profession and to the people. When available it will become a powerful weapon in the battle against government dominated medicine. The House of Delegates recommended also that the Board of Trustees and the Council on Medical Service emphasize a nationwide organization of locally administered prepayment medical plans sponsored by medical societies. This move toward the development of a standard prepayment plan for medical bills, with an insurance policy recognized anywhere in the United States and bearing the mark of acceptance by the American Medical Association, will be another valuable tool in meeting the needs of the American people. We are developing a system of medical care consistent with the American democracy. Such activity in behalf of the people is the best public relations that could be evolved. Let us use every possible vehicle of dissemination of information to tell the people what we are doing.

DISCUSSION

Mr. John Hunton, Executive Secretary of the California Medical Society: Public relations, as Dr. Fishbein has pointed out, has come into being in the twentieth century and just now is becoming recognized by the medical profession as a problem to be met by the profession. A few years ago at one of our meetings I happened to be in a conversation with two gynecologists, and one of them was talking about the fees that he charged. The other said "Who sets your fees?"

"I set my own fee."

"What do you mean, you set your own fee?"

"Why, I tell every patient what my fee is going to be, and that is what it is."

"Wait a minute! You don't set your own fee. A woman comes to you and you examine her and you say she should have a certain piece of surgery performed. She says 'How much will it cost me?' You say it will be $200, and she replies 'I want to talk it over with my husband.' The next week you see her in a hospital and somebody else is operating on her, and he doesn't charge the high fee that you do. Or she comes in and you say 'My fee is $200.' You operate on her and send her a bill for $200, and she pays you $100. Who sets your fee? The public sets your fee—your patients set your fee. You are not doing it yourself at all."

Not only does the public set the fees, but the public actually controls conditions under which medicine must be practiced. We are recognizing that gradually in some of the states; it has been recognized a little earlier in some other states. There is a realization coming to all of us that the public must be the controlling factor, the factor whose voice is going to be heard and to which we must listen. We see it in our own state; we see it in the national Congress. These proposals for compulsory sickness insurance are not new. We have had them in California since 1918. We have been fighting them violently. We had a terrific battle last year. They represent the voice of one segment of the public, the left wing group: a group which must be recognized and which actually represents a demand of a general character by the public for more readily available medical care on a budget basis at a price which the public can afford to pay. If the medical profession itself cannot provide that type of service, the government is going to do it for the people. We all know the way we want it. We want to do it ourselves and we don't want to do it under government domination.

In any public relations program a public relations expert starts his educational work at what he calls the point of contact. In the bank he will start with the bank tellers, the people who stand behind the wickets and meet the public. To the people coming into the bank the man behind the wicket is the bank. He is the person the depositor talks to; he represents the point of view and the policy of the institution. Unfortunately, in the medical profession, as large and as widespread as it is, and not representing a group of people in the employ of one employer, and therefore not amenable to a company educational program, the attack must be different. The approach has to be of a different nature. However, we still must do our educational work at the point of contact, which is the individual physician who sees his patients. We all know that one physician making a poor impression on a patient can offset the good work that a hundred physicians can do who really go out of their way to represent the medical profession properly and in a true light to the public.

We were recently approached by a group of commercial insurance companies who had a complaint that about 5 per cent of the doctors performing surgery under the indemnification policy as written by that company were making what the insurance company said were gross overcharges. The charge for the surgery was terrifically out of line with the indemnifications outlined by the policy. Ninety-five per cent of the doctors were complying more or less, but their fees were more or less in line with what was allowed under the policies. Five per cent were overcharging to a point where their overcharges were reflected back in the attitude of the individual patients, and they in turn went back to their own groups and their own companies, and the insurance companies found themselves losing business on account of what the small minority of 5 per cent of the doctors were doing. They were doing more harm than the 95 per cent were doing good.

If you are going to start at the point of contact and educate the individual physician in public relations, it is our idea in California that we should start very early; we should start in the medical schools. At one time or other we have had several rather haphazard courses in medical economics in the medical schools; they have not been well organized. They have been disjointed and inconsistent. We will find one school putting on a pretty good course one year, and the next year they will say "It's too much trouble." We have found that when a good course is put on, and when it is voluntary, and an optional course, the students eat it up.

We are now planning to present a series of courses of this type in all of our four medical schools. Ted Wiprud has written a couple of books on the subject. I would like to pay tribute to him and to suggest that it be carefully considered in your own states. We are also having a little experiment in one of our large counties, Los Angeles County, which has a membership of about 3,600 physicians. The council of that society has voted that every new applicant for membership must undergo an indoctrination course and take an examination before he is admitted to membership. The idea is not to set up a barrier to keep him out; the idea is not to flunk a man on his examination; the idea is to make sure that every applicant for membership will go through a course of six meetings, which will include ethics, organization, history, malpractice, legislation and prepayment plans, and to let those applicants for membership know through that series of meetings that they have a responsibility jointly with the rest of the members and that they will be expected, as members, to assume their share of the responsibility and to handle themselves properly with the public—to let them know that they should not go off half-cocked on their own, and do something which will injure public opinion instead of improve it.

As Dr. Fishbein has stated, public opinion leads into legislation. We have had a lot of discussion in the last few years on legislation. We have had the Council on Medical Service and Public Relations established, and the Council is moving rapidly toward the fulfilment of the goal that a great many people throughout the country have had for a long time. Our legislators in our state capitals and in Washington reflect nothing but public opinion. They are representatives of the people. Sometimes I think they are misrepresentatives, but at least they are elected by the public, and fundamentally they are presumed to represent public opinion in the type of legislation which they introduce and which they pass or discard.

Our problem in medical public relations is to build our pyramid in the same fashion, to have the head of the pyramid extended into our legislative bodies so that when the matter of legislation comes up medical public opinion will influence the legislators. When legislation of any character comes up which will affect the practice of public medicine or the public health, then the medical profession as an organization will be well enough recognized and respected by the legislators so that they will take our word when it comes to testimony and when it comes to ideas on this, that or the other type of bill.

Most of us have had a lot of experience in our own states. The American Medical Association has had considerable experience in Washington along this line. That must be our ultimate objective, because after all if legislation of an adverse character is to be passed it is going to be a long time before it will be repealed again.

Dr. Fishbein has paid tribute to the job being done by the National Physicians' Committee. I think we have all seen the vast amount of literature that the National Physicians' Committee has put out. We have all seen that it has been highly effective. We all recognize that the National Physicians' Committee came into being because there was a definite need for it.

In my opinion the excellent work of the National Physicians' Committee could be better carried on if the National Physicians' Committee was actually a part of the American Medical Association.

The House of Delegates of the American Medical Association has given the National Physicians' Committee a nice pat on the back several times; however, it is still the National Physicians' Committee. If it could be the public relations department of the American Medical Association and be welded in as part of the Council on Medical Service and Public Relations, in my opinion it would be a much more effective organization. The same technics, the same formulas, the same personnel which have been effective so far could be made just that much more effective and could be utilized and made a definite part of the American Medical Association.

Mr. Edward Stegen, National Physicians' Committee: We owe a debt of gratitude to Dr. Fishbein for his extremely interesting and informative paper. A sound public relations program implies a careful internal and external analysis, an analysis that includes in its scope the people, the product or service, the need for the product of service, the public acceptance of the product or service, an analysis on the external side of what means and what avenues and what technics can be applied intelligently and legitimately to implement public acceptance, public understanding and public approval of the product or service. On the basis of an adequate analysis of a given problem with which public relations people must deal, planning has been good if the people are competent who are running the program; but frequently the work and the success of a given cycle of the program or effort is limited or liquidated by bad timing. Ivy Lee said that public relations was 50 per cent content and 50 per cent timing. We must think of public relations generally as an evolutionary process; in other words, public attitudes change. There are competitive elements in our society that change public attitude toward any given service or product. In any public relations program we must recognize the cyclic evolutionary aspect of the job.

Another instance of defect in many a good and well planned public relations program is the lack of coordination of effort. In a complicated problem, when you are dealing with many forces and many interests, numerous individual and group expressions, and when you are using all of the regularly accepted mediums to tell your story and to gain public acceptance, coordination is important; it must be a significant phase of planning and of operation. Effort must be made toward a uniformity of opinion and uniformity of expression of the people or the group that is being served. In my limited experience I once had the privilege of working with Mr. Cotton in an attempt to convince the people of this country that so-called remedial lending under the Uniform Small Loans Acts of the various states was a socially acceptable and useful device. The program was moving along satisfactorily until we discovered that all of the things we were saying and that had group acceptance by the people who were in the industry were being liquidated and placed in a critical position in many communities because of the individual expressions of people in their day-to-day job of doing business of lending money.

I don't suppose you can ever accomplish a total similarity of expression or total similarity of opinion. I do not think we are built that way. It is a problem that the public relations counsels and the public relations people must deal with, and an effort must be made constantly toward a uniformity of opinion in the group being served, to crystallize that uniformity of opinion into a uniformity of expression. The individual doctor enjoys such a distinct place in his community, and such a reverence from the people whom he serves, that all the contumely which from time to time has been heaped on the profession or the group by our critics has never actually come down to being a criticism of the individual doctor. The doctor is still an important and respected individual and a servant of his community. I believe that fact is most dramatically illustrated in some of the attacks which have come out of government agencies, where almost invariably and to a pattern the criticism begins "The American doctor is a great servant of his patients, and he is a well trained and effective physician." and then comes the hooker, "but—", and then the criticism of the group.

Dr. Fishbein brought clearly to point the fact that the job of public relations for medicine must begin with that individual who has that high percentage of public acceptance, the individual physician, that it must grow from there into the same kind of acceptance to the group, to the profession as a whole, or to any of the segmental organizations. That is really the problem which medicine faces today—to gain for the profession, for the organizations that represent the profession, the same kind of understanding on the part of the public and the same kind of acceptance which the public has so generously given to the individual doctor.

Mr. Hunton's comments on the relationship of the National Physicians' Committee and the American Medical Association were interesting. Although not identically so, but for pretty much the same reason that the California Medical Association retains public relations counsel and uses an organized professional group to handle these aspects of its problem of public relations, I think organized medicine has found it desirable and eminently useful to have an organization such as the National Physicians' Committee to act pretty much in that professional area and to do certain segments of the job which in every instance are not readily adaptable to the line organization.

Since I have the task of dealing with medical public relations, this observation has struck me as significant: Medicine as such, through its many, many organizations, state and county societies, the American Medical Association, has employed the regular mediums of public expression better and more intelligently than any other organized group I know of, and we can use that great and good acceptance of our expressions, which has grown out of it, as the most effective device to deal with our legislative problem. The legislator, as the author pointed out, is both a member of the public, a government servant if he belongs to your party, and if he isn't he is a bureaucrat, and he believes he can give the most intelligent expression of public opinion because he has been chosen on an elective basis to represent the public. To deal with him we have to lay a groundwork and use all of the mediums of public and mass education. In dealing with the legislator we can show a definite connection between what the people think and what the people want, and what he thinks the people want. I am sure I express the consensus of our opinions that Dr. Fishbein did a marvelous job in dealing with this topic.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Veterans Administration

A bill introduced by Senator Langer, North Dakota, S. 1817, proposes to provide for hospitalization and treatment of veterans in nongovernmental hospitals. It provides that, when any person entitled to medical care, treatment and hospitalization under the laws administered by the Veterans Administration cannot be treated or hospitalized at a government facility within a reasonable distance from the place of his residence, the Administrator of Veterans' Affairs will be authorized to provide for such medical care and treatment by private physicians and for hospitalization in a nongovernmental hospital. The administrator would be authorized to enter into agreements with private physicians and nongovernmental hospitals to provide the necessary medical care, treatment and hospitalization at specified rates determined by him to be fair and reasonable. H. R. 5383, introduced by Representative Barry, New York, proposes an appropriation of $1,500,000 to be expended by the Administrator of Veterans' Affairs in building a new hospital and diagnostic center in the city and state of New York.

Medical Care for the Needy

Senator Langer, North Dakota, proposes by S. 1838 to amend and extend the provisions of title I, title IV and title X of the Social Security Act to provide, among other things, hospital, medical and health services to needy aged persons, to dependent children and to the blind.

Hill-Burton Hospital Construction Bill

Hearings before a subcommittee of the House Committee on Interstate and Foreign Commerce on bills pending before the committee proposing a hospital building program originally scheduled to begin on February 25 have been postponed until March 7.

Miscellaneous

H. R. 5465, introduced by Representative Savage, Washington, proposes to aid the states in establishing and maintaining a scholarship and fellowship program in the colleges and universities. For the fiscal year 1946-1947 an appropriation of $35,000,000 will be authorized, for the fiscal year 1947-1948, $50,000,000, for the fiscal year 1948-1949, $65,000,000, and for each fiscal year thereafter, $80,000,000. H. R. 5353, introduced by Representative Robinson, Utah, would authorize the Secretary of War to convey certain lands situated within the Fort Douglas Military Reservation to the Shriners' Hospitals for Crippled Children.

STATE LEGISLATION

California

Bill Introduced.—S. J. R. 7-X proposes that the President of the United States and the Veterans Administration be memorialized to enter immediately into contracts with the Army and Navy to take over a sufficient number of hospitals, adequately staffed, to furnish hospital facilities for veterans.

Georgia

Bills Enacted.—H. R. 169 became Governor's Act No. 77 of the Acts of 1945 on Jan. 31, 1946. It provides for the submission to the voters of an amendment to the state constitution creating a State Board of Public Welfare. H. 732 became Governor's Act No. 623 of the Laws of 1945 on Feb. 1, 1946. It provides for the creation of a hospital advisory committee and will require all persons operating or in charge of any hospital, sanatorium, infirmary, maternity home, nursing home or similar institution to be licensed by the State Board of Health.

Kentucky

Bills Introduced.—H. 225 proposes that no physician, surgeon or registered nurse shall be denied the right to attend and treat any patient, by whom such physician, surgeon or registered nurse has been employed, in any hospital or institution in the state on account of his race. The proposal would further prohibit the denial to any person, on account of race, of the right to receive postgraduate or in-service training in medicine, surgery or nursing in any hospital or institution in the state.

Massachusetts

Bills Introduced.—H. 801 proposes the creation of a state board of registration of opticians and defines an optician as "a person engaged in the filling, compounding or reproducing of prescriptions of physicians or optometrists for ophthalmic lenses, eyeglasses or other optical appliances intended for the correction or treatment of defective vision or ocular anomalies of the human eye, and the mounting and fitting of the same to frames or supporting materials, and the adapting of such lenses, eyeglasses and appliances to the use of the wearer." Physicians and optometrists are specifically exempted from the provisions of this bill. H. 1417 proposes to authorize the commissioner of mental health to provide hospital facilities and hospital treatment for the care of mentally ill children. H. 1468, to amend the law relating to the restraint of patients in mental hospitals, proposes that "restraints" shall not include chemical or mechanical restraint in cases of contagious disease, during the administration of anesthesia, or following an operation or accident which has caused serious bodily injury, or during the administration of shock therapy, insulin treatment or any other recognized specific therapy.

Michigan

Bill Introduced.—S. 9-X proposes the appropriation of $750,000 to the board of regents of the University of Michigan for the construction and equipment of a new maternity hospital and a new children's unit in connection with the University of Michigan hospital.

Bill Passed.—H. 13-X passed the house February 11. It proposes the approval of a postwar emergency hospital program for the construction and equipment of a number of hospitals for mentally affected persons.

Mississippi

Bills Introduced.—H. 430 proposes the creation of a Mississippi Commission on Hospital Care with the duties, among others, of assisting in developing, promoting and encouraging a voluntary prepayment plan of hospitalization, or hospitalization insurance. H. 431 proposes the creation of a state medical education board to receive and pass upon applications for loans or scholarships made by students who are residents of the state and who desire to become physicians. The purpose of such loans would be to enable the applicants to obtain a standard four year medical education which will qualify them to become licensed, practicing physicians and surgeons within the state. H. 432 proposes an appropriation to the State Medical Education Board to provide loans or scholarships for citizens of the state who desire a medical education which would qualify them to become licensed and practicing physicians and surgeons within the state. S. 155, to amend the law relating to the licensing of nurses, proposes certain standards which a hospital must maintain in order to be recognized and approved as a training school for nurses. S. 181, to amend the law relating to the issuance of marriage licenses, proposes that both parties applying for a license to marry shall submit to a thorough medical examination by an active licensed physician in Mississippi, by a physician licensed to practice in any or all of the other states of the Union or the District of Columbia, by a commissioned medical officer on active duty in the armed forces of the United States, or by a medical officer of the United States Public Health Service, provided that said medical examination may be made free of charge by any full time county health officer licensed to practice medicine in Mississippi if the person examined is unable to pay for same. Medical examinations would include a standard serologic test or tests for syphilis.

Bills Passed.—H. 388 passed the house February 13. It proposes an appropriation to the State Board of Health for the conducting of a program of eradication and control of syphilis and other venereal diseases. S. 90 passed the senate February 11. It proposes to authorize the State Board of Health to maintain injunctive procedures to enjoin any person from the practice of any profession required to be licensed by said board when such person is practicing without first having obtained a license.

Missouri

Bill Passed.—H. 831 passed the house February 5. To amend the law relating to the appointment of deputy state commissioners of health, it proposes to authorize the county courts of any county to appoint as a deputy state commissioner of health a duly licensed qualified physician. The existing law requires only the appointment of a reputable physician.

New Jersey

Bills Introduced.—A. 45, to amend the medical practice act, proposes to admit to examination by the board of medical examiners persons otherwise qualified who instead of being licensed as a physician in some other state had served as an intern for at least two years in a hospital approved by the State Board of Medical Examiners. A. 47 proposes the establishment in the executive branch of the state government of a State Department of Health in which there shall be a Public Health Council authorized, among other things, to promulgate regulations which would constitute the State Sanitary Code. A. 66, to amend the law relating to divorce, proposes to authorize the granting of a divorce when either of the parties to the marriage has become incurably insane, provided that the person has been confined in an insane asylum for at least five years prior to the commencement of the action for divorce and provided further that it shall appear to the satisfaction of the court that the insanity is incurable, such satisfaction being based on the testimony of at least two reputable physicians. A. 90, to amend the workmen's compensation law, proposes, among other things, to authorize an injured employee to select to treat him any duly licensed physician, who must be recompensed by the employer. S. 75 proposes the enactment of an unemployment and cash sickness compensation law. S. 95, to amend the medical practice act, proposes that any applicant for a license to practice medicine and surgery who has been examined and licensed by the examining and licensing board of another state or by the National Board of Medical Examiners may be licensed without further examination provided he furnishes proof that for a period of at least one year within the period commencing Dec. 7, 1941 and ending Aug. 14, 1945 he has, while a commissioned officer of the medical corps of either the United States Army, the Army of the United States, the United States Navy, the United States Naval Reserve or the United States Coast Guard practiced medicine and surgery in the performance of his duties.

Bill Passed.—A. 69 passed the assembly February 11. It proposes to authorize the establishment and maintenance of blood banks to collect, process, store and distribute human blood and the various human blood derivatives, including special therapeutic and diagnostic serums, which are deemed of value in the treatment of sick and injured persons, and the prevention of certain diseases.

New York

Bills Introduced.—A. 896 and S. 830, to amend the law relating to the practice of optometry, propose that applicants must be citizens of the United States or must have declared an intention of becoming such. A. 898 and S. 827, to amend the law relating to the practice of podiatry, propose that applicants must be citizens of the United States or must have declared an intention of becoming such. A. 899 and S. 829, to amend the law relating to the practice of dental hygiene, propose that applicants must be citizens of the United States or must have declared an intention of becoming such. A. 983 and S. 821, to amend the penal law in relation to the right to dissect the dead body of a human being, propose that the husband, wife or next of kin of the deceased, when authorizing a dissection, shall do so by written instrument which shall specify the purpose and extent of the dissection so authorized. A. 1167, to amend the law in relation to hypnotic and somnifacient drugs, proposes to prohibit a pharmacist or druggist from furnishing a copy of the prescription to the patient. A. 1204, to amend the law relating to privileged communications, proposes to authorize a waiver of the privilege to be made in any litigation where the individual interests of the personal representative of a deceased person are deemed by the trial judge to be adverse to the interests of the estate. S. 755 proposes the enactment of a disability benefit law. "Disability" would be defined as "the incapacity on any day of a person to perform any employment because of physical or mental conditions." S. 801, to amend the unemployment insurance law, proposes to remove the exemption of charitable, scientific, literary or educational institutions therefrom. S. 802, to amend the unemployment compensation law, proposes that the illness or disability causing unemployment shall be certified under oath by a physician or surgeon duly licensed to practice in the state of New York or in any other state, territory or possession of the United States. S. 975, to amend the workmen's compensation law, proposes to authorize an injured claimant to have free choice of a duly authorized hospital for treatment of his injuries.

Bill Passed.—S. 556 passed the senate February 11. To amend the law in relation to hospital liens, it proposes that such liens shall not include personal services rendered by a physician or surgeon and that the rates charged by the hospital shall be deemed equivalent to the scheduled rates currently approved by the industrial commissioner and the superintendent of insurance for cases under the workmen's compensation law.

Virginia

Bills Introduced.—S. 149 proposes the creation of hospital authorities to engage in hospital construction, maintenance and operation. S. 166, to amend the law relating to hypnotic drugs, proposes that the words "dangerous drugs" shall include, in addition to preparations already so included, "Hormones, or hormone drug preparations, whether of natural origin, prepared from the so-called glands of internal secretion or endocrine glands, or whether synthetically produced, by whatsoever trade name or designation, or any compound or mixture thereof; except preparations intended for external use containing hormones in combination with other ingredients unfit for internal administration." No person would be able to sell or give away any such drug except on the prescription of a doctor of medicine, doctor of dental surgery or doctor of veterinary surgery, lawfully practicing his profession, and prescriptions for hormones could, on written authorizations on the face of the prescription by the prescriber, be refilled a definite number of times as indicated.

Washington Letter

(From a Special Correspondent)

Feb. 18, 1946.

Controversial Legislation Before Congress

Among controversial items of legislation slated for consideration by Congress during the coming week are extension of the Office of Price Administration past June 30, universal military training and the federal school lunch program. The House Military Affairs Committee today begins the final week of hearings on universal military training legislation. There is considerable opposition to the bill to make permanent the federal school lunch program, being considered by the House. Opponents consider it the first definite step toward federal control of public schools. Hearings will continue on efforts of President Truman to have Edwin Pauley nominated as Undersecretary of the Navy, which has already resulted in resignation of Interior Secretary Ickes.

Use of Hospital Ships for Veterans Proposed

Until the hospital program of the Veterans Administration provides more beds, floating hospital ships are the answer to the acute shortage of facilities for veterans, according to Senator Mead, Democrat of New York. He said that both the Army and the Navy have excess hospital ships which could be used. Some ships are now being used to transport war brides to this country. War Secretary Patterson authorized General Omar N Bradley to announce that army engineers will take over the bulk of construction on the agency's $448,000,000 "skyscraper" hospital building program. Bradley described it as "the most gigantic hospital building program in the history of the world" and estimated that with the help of the engineers the hospitals could be completed in eighteen months to two years. Veterans are to have 183 permanent hospitals with a capacity of 151,500 beds. General Bradley also proposes a nationwide system of home town medical and hospital care for disabilities traceable to military service.

Red Cross Sees Busy Peacetime Role

The Red Cross estimates that its services to discharged veterans of the war will not reach their peak until 1975, basing this on the fact that veterans of 1918 are still asking help from the Red Cross in larger numbers than ever before. The organization reports that since Pearl Harbor 500,000 victims of domestic disasters have been given food, clothing, shelter and medical care. A total of $7,200,000 was spent meeting their needs. Through Red Cross educational programs 1,400,000 certificates were issued to students in home nursing, 700,000 in nutrition and 1,200,000 in water safety.

Lack of Progress in Preventing Deafness

Failure of the medical profession to make progress in preventing deafness was deplored by Vice Admiral Ross T. McIntire, Surgeon General of the Navy, addressing the twenty-fifth anniversary meeting of the Washington Society of the Hard of Hearing. Admiral McIntire said that virtually no headway had been made in this field in fifty years except in deafness related to disease. He reported that the Navy is now engaged in research at the Philadelphia Naval Hospital, where hard of hearing patients among naval and Marine Corps personnel are treated.

Army Cuts Physical Standards to Obtain 75,000 Men

The U. S. Army has lowered its physical standards so that 75,000 men once rejected can be called up for manpower needs, the War Department announces. The men will be obtained from the pool of 1,250,000 nonfathers from 18 through 25 years of age. These are classified mostly in 4-F but also include some classes in 2-A-L, 2-A-F, 2-C-L and 2-C-F.

Refutation of Charges of Cruelty in Animal Experimentation

Although one segment of the local press is agitating for antivivisection legislation in the District of Columbia, another newspaper has produced evidence that a dog on an operating table for experimental purposes received scientific pain prevention equal to that administered to a human being. The Army is quoted as follows: "No research capable of inflicting pain or suffering may be undertaken unless the animals are suitably anesthetized, or other steps have been taken to prevent suffering." Friends of Medical Research is quoted: "There is always anesthesia in an operation on a living creature. . . . Doctors study dogs to learn about human beings. . . . The law now safeguards all animals used in research. A laboratory dog is prepared for an operation with the care accorded a human being. It is also pointed out that army research is conducted in connection with established medical centers whose rules and regulations govern the investigators.

"Quick" Treatments Blamed for Increase in Venereal Disease

Dr. William P. Herbst, president of the Social Hygiene Society, stated here that quick, comparatively painless treatments for venereal disease have removed the "fear deterrent" and caused a "noticeable increase in reinfection." Dr. Ross Taggart, director of the Venereal Disease Bureau, also stated that since quick cures had been used an increasing number of patients had been returning for treatment as often as six times a year.

Extension of Planned Parenthood Urged

An international policy to balance population growths of the world was urged by D. Kenneth Rose, executive director of the Planned Parenthood Association of America in a luncheon meeting here. He advocated continued efforts to spread the planned parenthood doctrine in the United States, where he said increasing abortions currently are responsible for two thirds of maternity deaths and where two thirds of the children are born in the lowest economic group.

Surplus Medical Supplies for Veterans' Hospitals

The U. S. Army will retain enough surplus medical supplies and equipment for 100,000 veterans' hospital beds, it is reported here. A stockpile valued at $30 million includes about fifty critical materials. The Veterans Administration will get the materials for five years but will be allowed only twelve months' supply at a time to permit release of some for civilian medical uses.

Coming Medical Meetings

Aero Medical Association, Chicago, April 7-9. Dr. David S. Brachman, 1016 Dime Building, Detroit 26, Secretary.

Alabama, Medical Association of the State of, Birmingham, April 16-18. Dr. Douglas L. Cannon, 519 Dexter Ave., Montgomery 4, Secretary.

American Association of Anatomists, Cleveland, April 4-6. Dr. Eliot R. Clark, University of Pennsylvania School of Medicine, Philadelphia 4, Secretary.

American Association of Pathologists and Bacteriologists, Chicago, March 8-9. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland, Secretary.

American Physiological Society, Atlantic City, March 11-15. Dr. Wallace O Fenn, 260 Crittenden Blvd., Rochester 7, New York, Secretary.

American Society for Experimental Pathology, Atlantic City, March 11-15. Dr. Harry P. Smith, 630 W. 168th St, New York 32, Secretary.

American Society for Pharmacology and Experimental Therapeutics, Atlantic City, March 11-15. Dr Raymond N. Bieter, University of Minnesota Medical School, Minneapolis, Secretary.

American Surgical Association, Hot Springs, Va, April 2-4. Dr. Warfield M Firor, Johns Hopkins Hospital, Baltimore 5, Secretary.

Arkansas Medical Society, Little Rock, April 14-15. Dr. W. R. Brooksher, 602 Garrison Ave, Fort Smith, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, March 5-8. Dr Warren W. Furey, 30 North Michigan Ave., Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, March 18-21. Dr. John G. Young, 1719 Pacific Avenue, Dallas 1, Director of Clinics.

Federation of American Societies for Experimental Biology, Atlantic City, March 11-15. Dr D. R. Hooker, 19 West Chase Street, Baltimore 1, Secretary.

Iowa State Medical Society, Des Moines, April 17-19. Dr. John C. Parsons, 406 Sixth Ave., Des Moines 9, Secretary.

Medical Library Association New Haven, Conn, March 25-27. Miss Frida Pliefke, 2000 Medical Arts Bldg, Minneapolis 2, Secretary.

Missouri State Medical Association, St. Louis, March 24-26. Dr. Ralph L Thompson, 634 N. Grand Blvd, St Louis 3, Secretary.

New Orleans Graduate Medical Assembly, New Orleans, April 1-4. Dr. Joseph S. D'Antoni, 1430 Tulane Ave, New Orleans 13, Secretary.

Postgraduate Institute of the Philadelphia County Medical Society, Philadelphia, April 9-12. Dr. George P. Muller, 301 S. 21st St, Philadelphia, Director.

Southeastern Surgical Congress, Memphis, Tenn, March 11-13. Dr. Benjamin T. Beasley, 45 Edgewood Ave. S E, Atlanta 3, Georgia, Secretary.

Tennessee State Medical Association, Knoxville, April 9-11. Dr. W. M. Hardy, 706 Church Street, Nashville, Secretary.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

New Bureau of Hospital Inspections.—Dr. Julius B. Askew, on assignment to the California Department of Public Health by the U. S. Public Health Service, has been appointed chief of a new bureau of hospital inspections.

Personal.—Dr. Donovan O. Kraabel, formerly medical director at the Santa Rosa army air base, has been appointed medical director of the Sonoma County Hospital.——Dr. Allen E. Stamler has been appointed health officer of Corcoran in Kings County, succeeding Dr. Ernest C. Foster.——Dr. Rudolph B. Toller, Benedict, has been appointed superintendent of the Stockton State Hospital, succeeding Dr. Margaret H. Smyth, and Dr. Melvin J. Rowe superintendent of the Norwalk State Hospital, succeeding Dr. Edwin Wayte. The changes will take effect March 1, after which both Dr. Smyth and Dr. Wayte will be retired.

Changes in State Health Department Staff.—Dr. Malcolm H. Merrill, San Francisco, has been appointed deputy director of the California Department of Public Health, continuing as chief of the division of laboratories, a position he held since 1941. Dr. Merrill joined the department in 1937 as chief of the then newly formed bureau of venereal diseases. The position of chief of the division of medical services is now occupied by Dr. Robert Dyar, Stockton, recently released from the Army Air Force. Prior to his entering service in April 1942 Dr. Dyar directed the joint syphilis epidemiologic study in San Joaquin Local Health District, which was sponsored by the international health division of the Rockefeller Foundation, the health district and the state department of public health. Dr. Philip K. Gilman, San Anselmo, president of the California Medical Association, has been appointed chief of hospital surveys of the department.

ILLINOIS

Study of Dental Caries.—Fluorine will be added to the drinking water in Evanston in a new study conducted jointly by the Evanston Health Department, the Walter G. Zoller Memorial Dental Clinic, University of Chicago, and the department of public health dentistry of the Illinois State Health Department to study its effect on the incidence of dental caries. The superintendents of the schools have agreed to cooperate in making dental examinations of school children. The study in Evanston is based largely on the 1939 epidemiologic studies of the U. S. Public Health Service of school children of Evanston, Oak Park and Waukegan, communities which use fluorine-free Lake Michigan water; and Aurora, Elmhurst, Joliet and Maywood, which obtain their water from deep wells containing approximately 1 part per million of fluorine. Their findings indicate that those using fluorine-free water experienced about 2 6 times more dental decay than those drinking water containing fluorine. In order to determine the present incidence of tooth decay in Evanston, all school children in the age range of 6 to 8 and 12 to 14 years inclusive will be examined before fluorine in the concentration of 1 part per million is added to the drinking water. Reexaminations will be made at one or two year intervals and the results compared as the study progresses. The study will be continued until at least one group of children who have been exposed to fluorine throughout their entire life—prenatal and postnatal—have reached the age of 14. Each examination is to be made with care in order that as many as possible of the very early carious lesions of the proximal surfaces may be found and recorded. An x-ray examination is to be made at the time of the clinical examination. This is for the purpose of discerning those carious processes which are too small to be recognized by clinical methods. Chemical analyses of the food available in Evanston markets will be made from time to time in order to determine the fluorine content. Very frequent chemical analyses for the determination of the fluorine content of the water obtained in all parts of the city will be made. Samples of deciduous teeth which are shed and permanent teeth which must be extracted will be used to determine the amount of fluorine deposited in the dental tissues. The study as well as the methods employed has been approved by the appropriate committees of the North Suburban Branch of the Chicago Dental Society and the North Suburban Branch of the Chicago Medical Society. It is to be hoped that such a detailed study will give considerable information of value on the control of dental decay by the use of public health methods

Chicago

Clinical Conference.—The Chicago Medical Society will hold its second clinical conference at the Palmer House, March 5-8. Among the speakers will be:

Dr. Stanley Gibson, The Significance of Heart Murmurs in Children
Dr. Albert C. Furstenberg, Ann Arbor, Mich , Conservation of Hearing
Dr. Wingate M. Johnson, Winston Salem, N. C , The Management of Patients with Ulcer.
Dr. Charles C. Lund, Boston, Burns
Dr. Kendall Emerson, New York, Tuberculosis.
Dr Robert L Sanders, Memphis, Tenn , The Management of Obstructive Lesions of the Colon
Dr. Irvine H Page, Cleveland, Hypertension
Dr. Eben J. Carey, [illegible] Muscular Dystrophy.
Dr. Roger I Lee, [illegible]
Dr. Elexious T B[illegible]
Dr Peter C Kron[illegible] Should be Recognized by General Practitioners.
Dr Theodore L Squier, Milwaukee, Hay Fever and Asthma
Dr Joseph H. Chivers, Coordination of the Activities of the Industrial Physician and the Private Physician
Drs Woodruff L Crawford, Nordahl O Gunderson and Edward H. Weld all of Rockford, Ill , Polio Epidemic at Rockford.
Ancel B. Keys, Ph D , Minneapolis, Experimental Studies of Starvation on Men.
Dr Walter C. Popp, Rochester, Minn , X-Ray Therapy of Acute Infections.
Dr Edward Tolstoi, New York, The Management of the Healthy and Sick Diabetic.
Dr. Herman L Kretschmer, Kidney and Ureteral Stones.
Dr Priscilla White, Boston, Diabetes and Pregnancy.
Major W Allen Conroy, M C , Anesthesia
Dr Henry H. Turner, Oklahoma City, Endocrine Problems of Childhood
Dr Charles Mazer, Philadelphia, Endocrine Regulation of Menstruation and Me[illegible]
Dr Jean P. P[illegible] Disorders of Pregnancy
Dr. Ernest P. [illegible] Climacteric—Male and Female
Dr. Owen H. W[illegible] The Surgeon and the Ulcer Problem
Dr Earle B. Mahoney, Rochester, N Y., Shock.
Dr Robert Elman, St. Louis, Preoperative and Postoperative Care
Dr Sidney Farber, Boston, Some Chronic Diarrheal Disorders in Young Children.
Col Thomas T. Mackie, M. C., Washington, D. C , Tropical Diseases
Dr Roy R. Grinker, Indications for Specific Types of Psychiatric Treatment.
Dr. Hobart A. Reimann, Philadelphia, Antibiotics.
Dr. Claude S Beck, Cleveland, Surgery of the Heart.
Dr. Harrison H Shoulders, Nashville, Tenn , The Soul of Medicine
Dr Louis Schwartz, Bethesda, Md , Vocational Dermatoses
Lieut Col James J. Callahan, M. C , Washington, Treatment of Fractures
Dr. George T. Pack, New York, The Extension of Radical Surgery in the Treatment of Cancer.
Dr. William D Stroud, Philadelphia, Coronary Disease
Dr Edward W. Boland, Los Angeles, Rheumatoid Arthritis of the Spine.

A panel on hematology will be presented with Dr. Robert W. Keeton as moderator and the following speakers: Drs Howard L. Alt, Israel Davidsohn, Raphael Isaacs, Louis R. Limarzi and Steven O. Schwartz. A feature of the conference will be the presentation of certificates of appreciation to three "veterans of medicine in Chicago," Dr. Ludvig Hektoen, 82 years of age, emeritus professor of pathology, Rush Medical College; Dr. Isaac Arthur Abt, 78 years of age, emeritus professor of diseases of children, Northwestern University Medical School, and Dr. James B. Herrick, 84 years of age, emeritus professor of medicine, University of Illinois College of Medicine On Thursday evening the principal dinner speaker will be Col Philip Cochran on "Experience in Burma." The program also includes a luncheon each day with round table discussions by speakers from the morning session

KANSAS

Changes in Health Personnel.—Dr. Leon Bauman has been appointed full time health officer of Labette County, succeeding Dr. Oscar Harvey, Parsons, who was transferred by the U. S. Public Health Service to Sioux Falls, S. D. Dr. Donald E. Bux, Manhattan, who was recently released from military service, has been named health officer of Cherokee County. Ferrin B. Moreland, Ph D., Iowa City, has been placed in charge of the department of chemistry, division of public health laboratories, Kansas State Board of Health

Health Education Workshop.—A health education workshop sponsored by the state department of education, the state department of health and Kansas State University will be held at the university, Lawrence, July 8-12. The purpose of this workshop is to provide teachers, parents, supervisors, custodians and students an opportunity for intensive study of school and community health problems affecting the health and cation of the child. Study groups and individual conferences may be planned wherein school, home and health personnel may discuss common problems with the hope that a better understanding of the total health education program may result.

KENTUCKY

Commonwealth Fund Visiting Professorships.—Dr. John W. Moore, dean of the University of Louisville School of Medicine, on February 5 announced a group of commonwealth visiting professorships that have already participated in the current school year:

Capt. David B. Foster, M. C., Battle Creek, Mich., visiting professor of neurology and neurologic surgery.
Dr. Carl J. Wiggers, Cleveland, visiting professor of physiology.
Lieut. Col. Brian Blades, Washington, D. C., visiting professor of surgery.
Dr. Carl C. Speidel, Charlottesville, Va., visiting professor of anatomy.

All visiting professors have given special lectures to the students and staff on subjects chosen from their own studies. Those of them with clinical interests have held special clinics and ward rounds, while the visitors with laboratory interests have given laboratory demonstrations of special technics. All visiting professors have been selected as guest speakers at the regular meetings of the Jefferson County Medical Society.

MARYLAND

Winford Smith Leaves Johns Hopkins Hospital.—Dr. Winford H. Smith, since 1911 director of Johns Hopkins Hospital, Baltimore, has announced his retirement, effective March 31. Dr. Edwin L. Crosby Jr., assistant director since 1940, has been named to succeed Dr. Smith. The latter graduated at Johns Hopkins University School of Medicine in 1903 and Dr. Crosby at Albany Medical College in 1933.

MISSOURI

Society to Receive Bequest Under Physician's Will.—The will of Dr. Paul F. Stookey, Kansas, who died in November, provided that after his widow's death half of the estate should go to St. Mary's Hospital and half to the building fund of the Jackson County Medical Society.

Loan Fund Named for Iberia Physician.—Iberia Junior College recently created a loan fund to assist young men and women to become physicians and nurses in memory of the late Dr. John L. Benage, one of the alumni of the college. The physician, who died in June 1945, graduated in a class of five at the college in 1895. In 1901 he graduated at St. Louis College of Physicians and Surgeons, entering private practice in Iberia the same year. In 1914 he moved to Lebanon.

State Medical Meeting.—The Missouri State Medical Association will hold its scientific meeting at the Jefferson Hotel, St. Louis, March 24-26 under the presidency of Dr. Arthur S. Bristow, Princeton. Included in the program, which has been divided into four sessions, on blood, on the chest, on the kidney and hypertension and on electrolyte and water balance, are:

Dr. Harry Agress, St. Louis, Experiences with Blood Banking in Europe and Application of Blood Banks to Civilians.
Dr. Henry C. Allen, St. Louis, Clinical Significance of the Rh Factor.
Dr. Leo J. Wade, St Louis, Recent Observations on Anemia in Scurvy.
Dr. Carl V. Moore, St. Louis, The Antianemic Activity of Folic Acid.
Dr. Jay A. Myers, Minneapolis, Tuberculosis.
Dr. Ralph A. Kinsella, St. Louis, The Pneumonias.
Dr. Evarts A. Graham, St. Louis, Chest Tumors.
Dr. James L. Mudd, St. Louis, Chronic Suppurations.
Lieut. Col. Brian B. Blades, St. Louis, War Injuries to the Chest.
Dr. Leroy Sante, St. Louis, X-Ray of Chest.
Dr. Burton E. Hamilton, Boston, The Heart in Pregnancy.
Dr. William H. Olmsted, St. Louis, Recent Advances in Renal Function Tests.
Dr. Edward Massie, St. Louis, Clinical Correlations Between the Kidney and Hypertension.
Dr. Dalton K. Rose, St. Louis, Renal Lithiasis: Recent Advances in Treatment.
Dr. Edward H. Reinhard, St. Louis, Renal Insufficiency in Extrarenal Disease.
Dr. Raywood O. Muether, St. Louis, Normal Mechanisms and Methods of Administration and Dangers.
Dr. Alexis F. Hartmann, St. Louis, Problems in Pediatrics.
Dr. Robert Elman, St. Louis, Problems in Surgery.
Dr. James B. Stubbs, St. Louis, Problems in Medicine.

NEW JERSEY

Society of Surgeons.—The Society of Surgeons of New Jersey held its annual meeting in Plainfield January 30. Among the speakers were:

Dr. William B. Fort, Plainfield, Gynecology in the Child Bearing Period.
Dr. Paul Geary, Plainfield, Surgical Treatment of Thoracic Disease.
Dr. Nathaniel B. Stanton, Plainfield, A Device to Simplify End to End Anastomosis of the Large Bowel.
Dr. Thomas M. Morris, Plainfield, Urologic Accidents During Abdominal Surgery.

Treatment of battle casualties in World War II was discussed by Drs. Charles A. Hoffman, Plainfield, Charles T. Steffens, Dunellen, and Spencer T. Snedecor, Hackensack. Major Gen. Norman T. Kirk, surgeon general of the Army, addressed the dinner meeting on "The Remaining Task." Dr. Joseph H. Oram, Paterson, was elected president of the society and Dr. Walter B. Mount, Montclair, reelected secretary.

NEW YORK

Physician Honored for Twenty-Five Years' Service.—Dr. David B. Jewett, Rochester, was given a tea January 16 to observe his recent completion of twenty-five years' service as chief of the medical service of Genesee Hospital. According to the Rochester *Democrat and Chronicle* Dr. Jewett, who has been associated with Genesee Hospital since he served his internship there, has been named emeritus director of medicine, a newly created position. Dr. Charles Boller, Rochester, formerly a member of the medical staff, is the new medical director.

Spa Water Used in Therapy of Rheumatic Disease.—A long term experiment on treatment of chronic rheumatic ailments at the Saratoga Spa was inaugurated January 16 by Dr. Walter S. McClellan, Saratoga Springs, medical director. A group of patients with various rheumatic conditions will receive a series of treatments involving use of natural spa mineral water and water fortified with additional radioactive substances. The Saratoga Spa is owned by the state.

Public Meeting on Cancer.—February 28 has been designated cancer teaching day in Jamestown. The program, which is presented under the auspices of the Medical Society of the County of Chautauqua, the Jamestown Medical Society, the Medical Society of the State of New York and the state division of cancer control, will be conducted by:

Dr. Louis C. Kress, Buffalo, What the Public Should Know About Cancer.
Dr. Clyde L. Randall, Buffalo, Malignancies of the Uterus.
Dr. Samuel J. Stabins, Rochester, Cancer of the Breast.

Prizes to Be Awarded.—The Merrit H. Cash Prize and the Lucien Howe Prize will be open for competition at the next annual meeting of the Medical Society of the State of New York. The Lucien Howe Prize of $100 will be presented for the best original contributions on some branch of surgery, preferably ophthalmology. The author need not be a member of the Medical Society of the State of New York. The Merrit H. Cash Prize of $100 will be given to the author of the best original essay on some medical or surgical subject. Competition is limited to the members of the Medical Society of the State of New York who at the time of competition are residents of New York. All essays must be presented not later than April 1 and sent to Dr. Gordon Heyd, chairman of the committee on prize essays of the Medical Society of the State of New York, 292 Madison Avenue, New York 17.

New York City

Rabies Quarantine Extended.—The New York City State Department of Health has continued its antirabies quarantine in the boroughs of Brooklyn and Queens for a period not exceeding six months from February 3.

The Rothschild Lecture.—Selman A. Waksman, Ph.D., microbiologist, Agricultural Experiment Station, New Brunswick, N. J., will give the eighth Marcus A. Rothschild Lecture at Beth Israel Hospital, March 6, on "Streptomycin: Isolation, Nature and Application."

The John Wyckoff Lectures.—Dr. Eugene M. Landis, George Higginson professor of physiology, Harvard Medical School, Boston, gave the John Wyckoff Lectures on "Interactions of Vascular Volume and Circulatory Function" at the New York University College of Medicine. The first lecture was given January 17 on "Quantitative Aspects of Vascular Volume and Acute Circulatory Failure" and the second January 18 on "Cardiac 'Competence,' Venous Pressure and Vascular Volume in Relation to Exercise and Plethora."

Beth Israel Hospital Joins New York University in Postgraduate Work.—Beth Israel Hospital, under the direction of Dr. Maxwell S. Frank, medical director, is now participating in the postgraduate division of New York University College of Medicine. Dr. William Goldring, associate professor of medicine at the medical school, has been appointed liaison officer between the college and the hospital. For many years undergraduate elective courses in internal medicine have been given at Beth Israel Hospital. Under the more active affiliation, postgraduate courses may be offered in all services of the hospital. Plans are also being considered whereby residents at the hospital can secure training in the sciences at the college.

Personal.—Dr. Arthur C. Allen, who has served in the Army of the United States for the past three and a half years as pathologist at the Army Institute of Pathology, Washington, D. C., has been appointed associate professor of pathology at New York Medical College, Flower and Fifth Avenue Hospitals.——Dr. Eleanor M. A. Campbell, co-founder of the Judson Health Center, was guest of honor at a reception January 15 given in recognition of the twenty-fifth anniversary of the establishment of the health agency. Dr. Campbell founded the center twenty-five years ago with the late A. Ray Petty, pastor of the Judson Memorial Church.——Dr. Michael Lake has returned from a military leave of absence to his position of medical director of Macy's.

Premedical Society Affiliates with Alpha Epsilon Delta.—Skulls, premedical society of Cornell University Medical College, on January 12 became affiliated with Alpha Epsilon Delta, national honorary premedical fraternity, on installation as the New York Alpha chapter. The initiation of twenty-three active and five honorary members was conducted by Hugh E. Setterfield, Ph.D., associate professor of anatomy at Ohio State University College of Medicine, Columbus, and national president of Alpha Epsilon Delta, and Maurice L. Moore, Ph.D., assistant director of research, Frederick Stearns and Company Division, and national secretary. Skulls was organized at Cornell during the fall of 1927 under the auspices of Dr. James W. Papez, professor of anatomy, Cornell University Medical College, and with its installation became the thirty-fifth chapter of Alpha Epsilon Delta.

NORTH CAROLINA

Personal.—Dr. Basil T. Bennett, Jr., Trenton, Tenn., has been appointed medical director of Highland Hospital, Asheville, to succeed Dr. Robert S. Carroll, founder of the hospital. Dr. Otto Billig, Asheville, has been named clinical director. The hospital was founded by Dr. Carroll in 1904 under the name of Carroll's Sanitarium; in 1912 its name was changed to Highland Hospital and in 1940 the hospital was given to Duke University School of Medicine, Durham, to be used in connection with its department of psychiatry.——Dr. Roy McKnight, Charlotte, is the new president of the North Carolina State Board of Medical Examiners.

William Fleming Goes to Boston.—Dr. William L. Fleming, research professor of syphilology of the University of North Carolina School of Public Health, Chapel Hill, since 1939, resigned on Dec. 31, 1945 to become chief of the genito-infectious clinic and associate professor of medicine at the Boston University School of Medicine, Boston, effective January 1. Dr. Harold J. Magnuson, Baltimore, passed assistant surgeon of the U. S. Public Health Service, has been appointed research professo: [illegible] medicine in the School of Public Health, [illegible] Dr. Magnuson has been first assistant to Dr. Harry Eagle in the experimental syphilis laboratories at Johns Hopkins University since 1943.

OHIO

Claude Perry Named Acting Chairman of Department.—Dr. Claude S. Perry, Columbus, has been named acting chairman of the department of ophthalmology, Ohio State University College of Medicine, Columbus, with the rank of associate professor. Dr. Albert D. Frost, professor and head of the department of ophthalmology, died Nov. 15, 1945.

Personnel Changes of State Association.—Mr. George H. Saville, who joined the headquarters staff of the Ohio State Medical Association in May 1935 as assistant executive secretary, has been named director of the department of public relations of the association, effective January 1. The position has been vacant since March 1, 1943. Mr. Saville, who will continue as assistant executive secretary, has been serving also as news editor of the *Ohio State Medical Journal*. Mr. Hart F. Page has been named to fill this position and serve as assistant to the director of public relations. Mr. Page was recently released from the navy.

Mental Health for Every One.—The Welfare Federation of Cleveland devoted four sessions to the discussion of mental health at its fourth annual health and welfare institute in the Carter Hotel, Cleveland, February 19. "Mental Health for Every One" was the theme of the sessions. At one session on "Mental Health in the Wake of War" Dr. Douglas D. Bond, director of the division of psychiatry at University hospitals, Cleveland, was chairman, and speakers included Lieut. Col. Oscar B. Markey, Cleveland, consultant in psychiatry for the United States 10th Army; Dr. Ewing H. Crawfis, Lima, superintendent of Cleveland State Hospital and consultant to Selective Service boards, and Dr. Edward J. Humphreys, assistant director of the Ohio state division of mental hygiene.

PENNSYLVANIA

Geisinger Hospital Receives $100,000.—The George F. Geisinger Memorial Hospital, Danville, has received a gift of $100,000 from Mr. C. S. Woolworth, recent chairman of the board of the Woolworth stores. The gift is an outright one and is to be used for any purpose to which the trustees wish to put it. Mr. Woolworth has been a member of the advisory board of the hospital for many years.

Secretaries' Conference.—The Medical Society of the State of Pennsylvania will conduct a Secretaries-Editors Conference at the Penn-Harris Hotel, Harrisburg, March 7-8. The program will include the following speakers:

Drs. Francis F. Borzell, Philadelphia, Joseph W. Post, Philadelphia, and Louis W. Jones, Wilkes-Barre, Public Relations à la 1946.
Dr. Louis H. Bauer, Hempstead, N. Y., Medical Care for the American People Through Implementing the Profession's Program.
Major General Paul R. Hawley, M. C., Washington, D. C., Medical Care—Shall the Veteran Have Free Choice of Physician?
Dr. John A. Daugherty, Harrisburg, Pa., Medical Service Association of Pennsylvania.

Philadelphia

Hospital Provides Space for Returning Staff Members.—The Pennsylvania Hospital has established the Clinton Street Building to provide office space for members of its staff and especially returning medical officers connected with the institution.

Appointments at Temple.—Dr. Curtiss B. Hickox, Hartford, Conn., has been appointed professor and head of the department of anesthesiology at Temple University School of Medicine and Hospital. Dr. Dean A. Collins has been named professor of physiology, of which department Dr. Morton J. Oppenheimer is head.

Joseph Hughes Named Professor of Psychiatry.—Dr. Joseph T. Hughes, who has been serving in the U. S. Navy since 1943 and recently as chief of the neuropsychiatric service at the Philadelphia Navy Hospital, has been appointed professor of psychiatry at the Woman's Medical College of Pennsylvania to succeed the late Dr. Harold D. Palmer. Dr. Hughes graduated at the University of Pennsylvania School of Medicine in 1929.

Centennial Meeting of Society.—The Northern Medical Association of Philadelphia, second oldest medical society in the city and founded in 1846, will celebrate its centennial anniversary December 5 under the presidency of Dr. Myer Solis-Cohen, assistant director of health of Philadelphia. A special centennial committee has been named, of which Dr. Maurice S. Jacobs is the general chairman. The committee consists of the 1946 officers and the past presidents of the society. The 1946 president, Dr. Solis-Cohen, is the son of the late Dr. Jacob Solis-Cohen, who was president in 1875.

The Diabetic Survey.—Between December 1 and January 15, 296 diabetic patients were given x-ray examinations at the photofluorographic unit installed in the Maloney Building of the University of Pennsylvania Hospital as a part of the survey of diabetic patients carried on by Philadelphia health authorities (THE JOURNAL, Nov. 10, 1945, p. 758). Of the group x-rayed, 230 have been clinic patients and 66 private patients. Arrangements have been made for the diabetic clinic patients at Woman's Hospital and Presbyterian Hospital to be x-rayed while the unit is in the Maloney Building, where it will be located through February 28, when it will be moved to the metabolic division at the Philadelphia General Hospital.

TEXAS

Alpha Omega Alpha Lecture.—Dr. Edward L. King, professor of obstetrics, Tulane University of Louisiana School of Medicine, New Orleans, delivered the annual Alpha Omega Alpha Lecture at the University of Texas Medical Branch, Galveston, January 31 on "Clinical Aspects of the Rh Factors."

Personal.—Dr. and Mrs. J. G. Dodge, Abilene, observed their golden wedding anniversary recently.——Dr. Edward B. Rickey, Shafter, has been appointed director of the Jim Wells-Duval County Health Unit, Alice.——Dr. Sidney W. Bohls, Austin, director of the bureau of laboratories for the Texas State Department of Health, has resigned.

Special Society Election.—At a meeting of the Texas Society of Pathologists in Dallas, January 27, Dr. David A. Todd, San Antonio, was named president-elect. Other officers are Dr. May Owen, Fort Worth, president; Dr. Sidney W. Bohls, Austin, vice president; Dr. Charles T. Ashworth, Dallas, secretary, and Dr. Atticus J. Gill, Dallas, assistant secretary. The next meeting of the society will be held in Galveston, May 5.

VERMONT

Grants for Research.—The University of Vermont College of Medicine, Burlington, announces the following grants to its department of biochemistry: Armour and Company of Chicago have given a $2,000 grant to Edwin E. Hays, Ph.D., St. Louis, for studies on anemia. Grants given to the department of biochemistry for studies to be conducted under the direction of Harold B. Pierce, Ph.D.; assisting in the studies are Drs. Chester A. Newhall, Thomas B. Tomasi and Theodore H. Harward, all of Burlington. Miss Susan B. Merrow has been appointed nutritionist, R. F. Krause and Mrs. Ruth Law chemists and Mrs. M. B. Shepard assistant in the department. Milbank Memorial Fund, $17,700 for a two year study of the nutritional status of Vermont children. Merck and Company, Inc., $6,300 for a one year study of folliculosis among children.

VIRGINIA

Hospital Board Awards Prizes.—The Virginia State Hospital Board recently awarded prizes to physicians in the several state hospitals for meritorious papers submitted on varying subjects. Dr. Edgar L. Crumpacker, Roanoke, who is now on leave from the Eastern State Hospital in military service, and Dr. Walther Riese, Williamsburg, pathologist for the hospital, won first prize of $225 for a paper on "Studies in Brain Tumors." Dr. Paul Zwick, Manon, of the Southwestern State Hospital, won second prize of $125 for a paper entitled "Study of a Case of Fire Setting," and Dr. Vincent E. Lascara, Petersburg, of Central State Hospital, third prize of $50 on "A Study of the Use of Penicillin in the Treatment of Neurosyphilis." This is the second award made by the board (The Journal, Feb. 27, 1943, p. 693).

WASHINGTON

Personnel Changes in State Health Department.—Dr. Ralph R. Sachs, Richland, was appointed head of the field consultant section in the division of local health services, Washington State Department of Health, effective January 14. He was formerly public health supervisor for the Hanford Engineer Works, Washington's atomic bomb project. He graduated at Wayne University College of Medicine, Detroit, in 1937. Mr. Ralph L. Nielsen was recently appointed director of the hospital survey and health center facilities throughout the state as a prerequisite for formulating a plan for the coordinated development of hospital facilities. Mr. Nielsen was formerly assistant agriculture economist for the southwest region of the U. S. Department of Agriculture and was stationed at Berkeley, Calif.

WEST VIRGINIA

Annual Health Conference.—The annual state health conference will be held at the Prichard Hotel, Huntington, May 2-4. The state health department has already arranged for exhibits at the conference, and local health workers will be asked to provide displays. An institute for clerks of local health departments will be conducted in connection with the meeting to provide an opportunity for group discussion of current problems.

Personal.—Dr. Henry H. Hancock, Union, has been appointed by Governor Clarence W. Meadows as superintendent of the Andrew S. Rowan Memorial Home for aged and infirm white men and women at Old Sweet Springs, Monroe County, to succeed Dr. George P. Evans, Iaeger, who resigned effective February 1. Dr. Evans has served as superintendent since July 1, 1945. Previously he had been engaged in industrial practice at Iaeger in McDowell County.

Thomas Nale Goes to New York.—Dr. Thomas W. Nale, South Charleston, medical director at the South Charleston plant of the Carbide and Carbon Chemical Corporation, has been transferred to the New York office of the parent company, Union Carbide and Carbon Corporation, and will assume his new duties there shortly after the first of March. In New York Dr. Nale will be associated with Dr. Arthur G. Cranch, New York, toxicologist for the Union Carbide Company and serving as consultant in medical and toxicology problems for the medical directors of the various plants owned by the company. Dr. Nale has been medical director at the South Charleston plant since 1941. Previously he was connected with the state health department at Charleston.

Changes in Health Personnel.—Dr. Don V. Hatton, Williamson, has been appointed by the Public Health Council as full time county health officer for Mingo County. He succeeds Dr. Sixtus G. Bando, who is taking a course in public health at Johns Hopkins University School of Medicine, Baltimore. Dr. Charles Scott McKinley, Charleston, director of the bureau of industrial hygiene of the West Virginia State Health Department since May 1943, has resigned to accept appointment as medical director and plant physician for the Bakelite Company at Boundbrook, N. J., effective February 1. Dr. Clarence I. Butte Jr., Matoaka, recently returned from military service, has been appointed health officer for the city of Matoaka to succeed Dr. Frederic C. Goodall, who has moved to Princeton.

GENERAL

Examinations in Dermatology and Syphilology.—The American Board of Dermatology and Syphilology announces that the next oral examination for both A and B candidates will be held in San Francisco, June 28-29. The written examination for Group B will be held on April 22. The closing date for applications is March 1. Dr. George M. Lewis, 66 East 66th Street, New York, is secretary.

Planning Service for Children.—At least six state legislatures have set up special bodies to deal with services for youth. The states are Georgia, Illinois, Kentucky, Michigan, Missouri and New York. The program is being done in line with the proposal made by the National Commission on Children in Wartime in its recent recommendations for overcoming obstacles in planning for postwar needs.

Tests for Technicians.—The next examination by the American Orthoptic Council will be held in September and October. The written examinations will be held at various cities in the country, September 6. Only those passing the written examinations will be permitted to take the oral and practical tests, to be given in Chicago, October 12. Applications on official forms must be received before July 1. Address the American Orthoptic Council, 23 East 79th Street, New York 21.

The Kellersbergers Plan Tour for Mission to Lepers.—Dr. and Mrs. Eugene R. Kellersberger, New York, general and promotional secretaries respectively of the American Mission to Lepers, will begin a tour to certain points of the Western Hemisphere and Africa in March. They plan to return to the United States in the end of September. The tour is being made at the request of the board of directors of the American Mission to Lepers to strengthen the existing work and obtain more detailed information about it.

Director of Physical Medicine for Crippled Children.—Lieut. Col. George D. Wilson, on terminal leave from the army and formerly of Kernersville, N. C., has been appointed director of physical medicine for the National Society for Crippled Children and Adults, 11 South La Salle Street, Chicago 3. The appointment marks another step in the expanded program of the national society. Dr. Wilson will act in an advisory capacity in the society's program to assist communities throughout the country in meeting the medical problems posed by handicapped persons.

Meeting on Psychosomatic Problems.—The American Society for Research in Psychosomatic Problems will hold its annual meeting at the Hotel Pennsylvania, New York, May 11-12. The morning of the first day will be devoted to "Contributions of Military Medicine to Psychosomatic Medicine" and the afternoon session to "Psychosomatic Aspects of Orthopedic Practice." The annual dinner will be addressed in the evening by Dr. Bertram D. Lewin, New York, on "New Advances in Psychosomatic Investigative Technics." The headquarters of the American Society for Research in Psychosomatic Problems is located at 714 Madison Avenue, New York 21.

Symposium on Premedical Advisory Problems.—Alpha Epsilon Delta, national honorary premedical fraternity, in conjunction with the section on medical sciences, is arranging a special program on premedical advisory problems for the meeting in St. Louis of the American Association for the Advancement of Science. The meeting will be held at the Coronado Hotel, March 29. Dr. Carlyle F. Jacobsen, assistant dean, Washington University School of Medicine, St. Louis, will present a thorough discussion of the use and measurement value of the various objective methods of investigating the educational backgrounds of the student, and Dr. George T. Harding, Ohio State University College of Medicine, Columbus, will discuss the personality traits to be found and recognized in recommending students for the study of medicine. The second half of the program will deal with the length and content of the premedical curriculum. Dean Stanley Dorst, University of Cincinnati School of Medicine, will present the point of view of the medical school and Dr. William C. Cole, Rutgers University, New Brunswick, N. J., that of the liberal arts college.

Red Cross Field Directors in Veterans' Hospitals.—Red Cross field directors are now stationed at thirty-five Veterans Administration hospitals and others will be appointed to additional hospitals in the near future, it was announced January 28. Forming part of the recently established Red Cross Service in veterans' hospitals, these field directors work closely with Red Cross Gray Ladies, arts and skills instructors, motor and canteen corps workers, nurse's aides, dietitian's aides and others serving such institutions, to develop well rounded programs for disabled veterans. In addition they assist with distribution of athletic and other special equipment and supplies provided by the Red Cross production corps, camp and hospital councils and Junior Red Cross to cheer and comfort patients. Veterans Administration hospitals throughout the nation are being staffed by the Red Cross with permanent field directors as fast as they can be trained and assigned. The Veterans Administration has ninety-seven hospitals and homes in operation, and this number will grow as the construction program develops in the next few years.

Special Society Elections.—At the annual meeting of the American Otological Society, Inc., in 1944 Dr. Gordon Berry, Worcester, Mass., was elected president and Dr. William E. Grove, Milwaukee, vice president. The 1945 session of the society was canceled and the officers were held over. However, when Dr. Isidore Friesner, New York, secretary-treasurer of the society, died in September 1945, the council appointed Dr. Gordon D. Hoople, Syracuse, N. Y., secretary-treasurer pro tem to fill the unexpired term. The 1946 meeting of the society will be held at the Drake Hotel, Chicago, May 31-June 1.——Dr. Daniel C. Elkin, Atlanta, Ga., was named president of the Southern Surgical Association at its meeting in December at Hot Springs, Va. Dr. Alfred Blalock, Baltimore, was in 1943 elected to a term of five years as secretary. The next annual session will be held at the Homestead, Hot Springs, Va.——The American Congress of Physical Medicine is continuing its officers until the next annual meeting at the Hotel Pennsylvania, New York, September 4-7. Dr. Walter S. McClellan, Saratoga Springs, N. Y., is president-elect and Dr. Miland E. Knapp, Minneapolis, president. Marion G. Smith, B.Sc., 30 North Michigan Avenue, Chicago 2, is executive secretary.

Preceptorships in Pediatrics and Ophthalmology.—The American Board of Pediatrics announces that preceptorships will not be acceptable as preliminary pediatric training but may be used as refresher work and accredited time in practice by those who have completed their preliminary training. The board wishes to correct any other impression that has been made concerning preceptorships. The American Board of Ophthalmology announces that, with regard to the substitution of a preceptorship for residency in an ophthalmic hospital, it has always accepted such training in favorable cases. During the present overcrowding of facilities the board expects to take a liberal attitude regarding the requirements for training. It should, however, be pointed out that neither a residency nor a preceptorship suffices in itself to meet the requirements of the board. Each case will still be judged on its merits in determining fitness for examination. In entering on preceptorship certain conditions should be kept in mind. First the student will profit most after a sound course in the basic sciences of physiology of the eye and of vision, optics, pathology, bacteriology, chemistry, pharmacology, the relation of the eye to general disease; anatomy, embryology and neurology. This is essential for a residency, more so for a preceptorship. While men have been accepted from preceptors not specialists accredited by the board, it is obvious that the board has more information about those teachers who have passed its examinations.

Medical Science and Industry.—Section N of the American Association for the Advancement of Science will devote its meeting in St. Louis, March 27-30, to a symposium on medical science and industry. It is organized in cooperation with the Council on Industrial Health of the American Medical Association. A tentative program lists the following speakers:

Joyce C. Stearns, Ph.D., St. Louis, Atomic Disintegration.
Dr. Andrew H. Dowdy, Rochester, Controlled Nuclear Energy. Its Attendant Hazards and Benefits.
J. M. Dallavalle, New York, Health Protection in the Production and Use of Atomic Energy.
Dr. Burrill B. Crohn, New York, Trauma in Relation to the Gastro-intestinal Tract.
Dr. George G. Ornstein, Staten Island, N. Y., Trauma in Relation to Lungs and Pleura.
Dr. Alfred P. Solomon, Chicago, Traumatic Neuroses in Industry.
Dr. Paul D. White, Boston, Trauma and Heart Strain.
Major Gabriel Seelig, St. Louis, Compensation in Single Trauma Car-cinoma.
Dr. Robert Elman, St. Louis, Recovery and Convalescence as Related to Traumatic Injury.
Dr. Thomas H. D. Storms, Toronto, Canada, Functional Rehabilitation.
Orlo L. Crissey, Flint, Mich., Selective Job Placement.
Dr. Hyman Meltzer, St. Louis, Personality Problems as They Occur in Management Group.
Dr. Hugh Ross, Montreal, Quebec, Canada, The Psychiatric Component in Personnel Problems.
Dr. Raymond Hussey, Detroit, Scope of Occupational Health and Medicine.
Dr. Carl M. Peterson, Chicago, Program of the Council on Industrial Health of the American Medical Association.
Dr. Paul A. Neal, Bethesda, Md., The Toxicity of DDT to Man.
Dr. Warfield T. Longcope, Baltimore, The Importance of Researches on War Gases to Clinical Medicine.

Rockefeller Grant to National Health Council.—A special grant of $78,500 has been made to the National Health Council by the Rockefeller Foundation to support a program of coordination of the voluntary health agencies of the country, it was announced February 4. This grant, covering operations of the council for 1946, will be used to strengthen and unify the work of the nation's 20,000 privately supported health societies whose activities have been the subject of a study by the council over the past four years. Under a new director, who will head the organization, and with its own qualified field services, the council will be able to assume the leadership for which the national situation as well as the local agencies have been calling, it was stated. The Rockefeller Foundation's aid in 1921 made possible the establishment of the National Health Council and financed the Gunn-Platt study begun some four years ago to estimate the value of the existing voluntary agencies (The Journal, Dec. 8, 1945, p. 1037). The organization of a Citizen Planning Committee marked the first step to obtain lay sponsorship for the program (The Journal, February 2, p. 298). Under the Rockefeller Foundation grant the National Health Council plans for the coming year will include facilities for joint planning, joint activities and joint services for the national agencies, the organization of new and the strengthening of established health councils in cities throughout the country, and an active field service to give practical counsel to local agencies on their organization problems. In order to demonstrate the soundness of its program, the council hopes to finance demonstrations in the coordination of health agencies in a number of cities and in one state. It will cooperate closely with the Community Chests and councils and will study the possibilities of one unified fund raising campaign, based on the National War Fund technics for such of the national health agencies as wish to join in a united effort.

FOREIGN

New Indian Department of Health.—The government of India established on September 1 a department of agriculture, a department of health and a department of education in place of the existing single department of education, health and lands, it is reported. Sir Sardar Jogendra Singh, minister in charge of the conjoint department in the viceroy's executive council, will for the time being take charge of all three departments.

Proposed National Health Service.—During December a set of principles was drawn up and agreed on for a proposed national health service by the negotiating committee representing the British Medical Association, the Royal College of Physicians of London, the Royal College of Surgeons of England, the Royal College of Obstetricians and Gynaecologists, the Royal Scottish Medical Corporation, the Society of Medical Officers of Health and the Medical Women's Federation. The *British Medical Journal* states that all government proposals for a national health service should be looked on in terms of these principles, and when the principles are infringed in any one particular the medical profession should be able to unite itself in opposition. As long as none of these principles are infringed the profession should find no difficulty in cooperating with the government in working out the administration of a national health service. The principles are:

The medical profession is, in the public interest, opposed to any form of service which leads directly or indirectly to the profession as a whole becoming full time salaried servants of the state or local authorities.

The medical profession should remain free to exercise the art and science of medicine according to its traditions, standards and knowledge, the individual doctor retaining full responsibility for the care of the patient and freedom of judgment, action, speech and publication without interference in his professional work.

The citizen should be free to chose or change his or her family doctor, to choose, in consultation with his family doctor, the hospital at which he should be treated, and free to decide whether he avails himself of the public service or obtains independently the medical service he needs.

Doctors should, like other workers, be free to choose the form, place and type of work they prefer without governmental or other direction.

Every registered medical practitioner should be entitled as a right to participate in the public service.

The hospital service should be planned over natural hospital areas centered on universities in order that these centers of education and research may influence the whole service.

There should be adequate representation of the medical profession on all administrative bodies associated with the new service in order that doctors may make their contribution to the efficiency of the service.

CORRECTION

Bacillary Dysentery.—The title of Major L. A. Smith's paper published in The Journal, January 5, should have been "Bacillary Dysentery" rather than "Shiga Dysentery."

Deaths

Mazyck Porcher Ravenel ⊕ Columbia, Mo.; Medical College of the State of South Carolina, Charleston, 1884; born in Pendleton, S. C., June 16, 1861; professor of medical bacteriology and preventive medicine from 1914 to 1936 and since 1936 emeritus professor at the University of Missouri School of Medicine, where he had been director of the public health laboratory; bacteriologist, state live stock sanitary board from 1896 to 1904; chief of the laboratory of the Henry Phipps Institute in Philadelphia from 1904 to 1907 and formerly assistant medical director; professor of bacteriology at the University of Wisconsin in Madison from 1907 to 1914 and director of the state hygienic laboratory of Wisconsin from 1908 to 1914; first lieutenant in the medical reserve corps of the U. S. Army from 1910 to 1917, major in 1917 and lieutenant colonel in the medical corps of the U. S. Army from 1917 to 1919; in 1913 delegate from the Section on Preventive Medicine and Public Health, American Medical Association and chairman 1913-1914; member of the National Advisory Health Council, Public Health Service, American Philosophical Society, National Society for the Study and Prevention of Tuberculosis, serving as president, 1911-1912, American Public Health Association, president, 1920-1921, National Committee for Mental Hygiene, Wisconsin Anti-Tuberculosis Association and past president, American School Hygiene Association, and member of its council, International Association Against Tuberculosis, National Commission on Milk Standards, International Commission on Control of Bovine Tuberculosis and the U. S. Live Stock Sanitary Association, serving as president, 1911-1912; in 1922 appointed chief associate examiner in public health for the National Board of Medical Examiners and member of the council for the district of St. Louis; in 1933 made an honorary member of the Royal Sanitary Institute of Great Britain; in 1934 appointed a member of a committee to confer with federal authorities concerning a nation wide study of nutritional values of foods; in 1930 appointed consultant in public health and medical education to the Missouri State Board of Health; his former students presented to the University of Missouri School of Medicine an oil portrait of him; for sixteen years editor and editor in chief of the *American Journal of Public Health* of which he had been made editor emeritus in 1941; died January 14, aged 84, of pneumonia.

Andrew Francis McBride Sr., ⊕ Paterson, N. J.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1889; born on Jan. 4, 1869; served as mayor of Paterson and as state commissioner of labor; past president of the Passaic County Medical Society; a trustee of the Medical Society of New Jersey and in 1929 its president; member of the House of Delegates of the American Medical Association from 1938 through 1944; fellow of the American College of Surgeons; resigned in October 1945 after fifty-five years of service on the staff of St. Joseph's Hospital, where he interned; served during World War I; chairman of the board of directors of the Paterson Savings Institution, where in 1943 the "McBride Room" was dedicated to him and an oil portrait was unveiled; a member of the board of directors of the Citizens Trust Company; life member of the chamber of commerce; in 1939 created a Knight of the Order of St. Gregory the Great, Civil Class, by Pope Pius XII; died January 3, aged 76.

Henry Turner Brooks, New York; Albany Medical College, 1887; born in Baltimore in 1861; formerly instructor, adjunct professor and professor of pathology at the New York Post-Graduate Medical School; consulting pathologist to the New Rochelle (N. Y.) Hospital, Liberty (N Y.) Sanitarium, St. Mark's Hospital and Beth Israel Hospital; honored in 1945 by the Albany Medical College Alumni Association with a citation for fifty years of meritorious service to humanity; civil referee for the eastern division of the medical branch of the army during World War I; author of "Manual of Clinical Microscopy and Chemistry," translated from the German, in 1904, "Use of Microscope," "General and Special Pathology" and "Trichinosis"; editor of the *New York Post-Graduate Medical Journal* from 1902 to 1912; died in the New Rochelle (N. Y.) Hospital January 1, aged 84, of bronchopneumonia, cerebral hemorrhage and cerebral arteriosclerosis.

David Clark Hilton ⊕ Lincoln, Neb.; Rush Medical College, Chicago, 1903; born near Dorchester, Neb., April 23, 1877; formerly professor of surgical anatomy at the Nebraska College of Medicine and Surgery and professor of biology at the Cotner University; fellow of the American College of Surgeons; member of the American Association for the Advancement of Science and the Nebraska Ornithological Union, of which he was a past president; one of the organizers of the 110th Medical Regiment of the Nebraska National Guard in 1923, at which time he was commissioned a lieutenant colonel; later promoted to a full colonelcy and placed in command of the regiment; in 1940 placed on the inactive list with the rank of brigadier general; surgeon, Bryan Memorial Hospital; consulting surgeon, Veterans Administration Facility; died December 12, aged 68, of coronary sclerosis.

John Smith Wilson, Poughkeepsie, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1887; member of the American Medical Association; past president of the Dutchess County Medical Society; served during the Spanish-American War and World War I; chairman of the local draft board during World War II; served as health officer of Poughkeepsie and as alderman from the Sixth Ward; for fourteen years school commissioner and in 1919 president of the board of education; served on the staffs of the Wassaic State School, Wassaic, Matteawan State Hospital, Beacon, Harlem Valley State Hospital in Wingdale, Hudson River State Hospital, St. Francis Hospital and the Vassar Brothers Hospital, where he died January 1, aged 80, of cerebral hemorrhage.

Philip Hale Pierson ⊕ San Francisco; Harvard Medical School, Boston, 1913; born in China in 1886; clinical professor of medicine (tuberculosis) at the Stanford University School of Medicine; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; vice president of the National Tuberculosis Association, which he served as a member of the board of directors; consultant in diseases of the chest, Community Hospital of San Mateo County, San Mateo, Hassler Health Home in Redwood City and the Veterans Administration Facility; chief of the department of tuberculosis, San Francisco Hospital and the Stanford University Hospital, where he died January 17, aged 59, of cerebral thrombosis.

Archibald Delap Smith ⊕ Garden City, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1902; member of the American Academy of Pediatrics; fellow of the American College of Physicians; past president of the Brooklyn Academy of Pediatrics and the Brooklyn Pediatric Society; member of the draft and appeal boards during World War I; head of a civilian defense medical unit in Garden City during World War II; consulting pediatrician, Rockaway Beach (N. Y.) Hospital and Dispensary and the Brooklyn Hospital, where he died November 22, aged 69, of coronary thrombosis.

Maximilian Stern ⊕ Daytona Beach, Fla.; Columbia University College of Physicians and Surgeons, New York, 1900; past president of the Volusia County Medical Society; fellow of the American College of Surgeons; attending urologic surgeon, Halifax District Hospital; consulting urologist, Deland Memorial Hospital, Deland, Harry Anna-Crippled Children's Home, Umatilla, the Hospital for Joint Diseases and the Harbor Hospital in New York; inventor of the "resectoscope," an instrument for the transurethral prostatic resection; died January 19, aged 68.

Waite Adair ⊕ Lorain, Ohio; Starling-Ohio Medical College, Columbus, 1911; served during World War I; died November 3, aged 60.

Fred Ernest Angle ⊕ Kansas City, Kan.; University of Kansas School of Medicine, Kansas City, 1926; at one time an officer in the U. S. Navy; fellow of the American College of Physicians; associate in medicine at his alma mater; attending physician, Providence, Bethany and St. Margaret's hospitals; died in the University of Kansas Hospital October 30, aged 45.

Robert Hodges Ariail ⊕ Laurens, S. C.; Medical College of the State of South Carolina, Charleston, 1929; interned at the Greenville City Hospital in Greenville; died November 12, aged 40, of angina pectoris.

Frederick E. Bauer ⊕ New York; University of the City of New York Medical Department, New York, 1888; one of the founders and director of the physical therapy department, Lutheran Hospital; at one time head of the physical therapy department at Fordham Hospital; died October 30, aged 80.

Ethel Remington Beede ⊕ Faribault, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1909; for many years on the staff of the Minnesota School for Feebleminded; died in Cheyenne, Wyo., October 13, aged 63, of coronary occlusion.

Robert B. Bennett, St. Charles, Mich.; Saginaw Valley Medical College, Saginaw, 1897; died in the Saginaw General Hospital, Saginaw, November 7, aged 73.

William Birnbaum ⊕ Tulsa, Okla.; University of Minnesota Medical School, Minneapolis, 1940; died in the Springfield Baptist Hospital, Springfield, Mo., November 9, aged 39, of injuries received in an automobile accident.

Sam Shirley Blackman Jr., Baltimore; Johns Hopkins University School of Medicine, Baltimore, 1926; associate professor of pathology at his alma mater; member of the American Association of Pathologists and Bacteriologists; associate pathologist at the Johns Hopkins Hospital; accidentally drowned November 6 in Chesapeake Bay, aged 44.

Edwin A. Bowerman ⊕ Buffalo; College of Physicians and Surgeons, Baltimore, 1895; an Affiliate Fellow of the American Medical Association; past president and secretary of the Buffalo Academy of Medicine; physician for the city police department for many years; died in Lancaster, Pa., October 22, aged 74, of cerebral hemorrhage.

Horace Russell Boyer ⊕ Glendale, Calif.; University of Maryland School of Medicine, Baltimore, 1903; on the staff of the Physicians and Surgeons Hospital; died November 9, aged 68, of coronary thrombosis.

Clarence Walden Brown ⊕ Rolling Prairie, Ind.; Indiana University School of Medicine, Indianapolis, 1931; interned at St. Catherine's Hospital in East Chicago; died November 1, aged 48, of acute auricular fibrillation and coronary occlusion.

Gilbert Thómpson Brown ⊕ Dayton, Ohio, Starling Medical College, Columbus, 1895; fellow of the American College of Physicians; on the staffs of the Miami Valley and St. Elizabeth's hospitals; medical director of the Gem City Life Insurance Company; died November 17, aged 76, of coronary thrombosis.

Harry Seth Bull ⊕ Auburn, N. Y.; Syracuse University College of Medicine, 1908; past president of the Cayuga County Medical Society; member of the Radiological Society of North America, Inc.; served during World War I; served on the staffs of the Mercy Hospital and the Auburn City Hospital, where he died January 4, aged 61, of carcinoma of the throat.

Archibald McDowell Burfoot, Fentress, Va.; Baltimore Medical College, 1906; member of the American Medical Association; past president of the Seaboard Medical Association; died November 25, aged 61, of angina pectoris and hypertension.

William Henry Burroughs ⊕ St. Louis; St. Louis University School of Medicine, 1923; died in St. John's Hospital October 19, aged 55.

John LeRoy Burton, Buhl, Minn.; University of Minnesota Medical School, Minneapolis, 1936; village health officer of Buhl and Kinney; treasurer of the school board; on the staff of the Virginia Municipal Hospital in Virginia and the Range Hospital; died October 31, aged 41, of injuries received in an automobile accident.

William Edward Code, Chicago; Illinois Medical College, Chicago, 1904; member of the American Medical Association; died October 29, aged 67.

Alfred Peters Cole, Ironton, Ohio; College of Physicians and Surgeons, New York, 1891; served during World War I; formerly medical director of the Hamilton County Home and Chronic Disease Hospital in Cincinnati; died October 29, aged 78, of coronary thrombosis.

William James Coleman, Newport, Ky.; Jefferson Medical College of Philadelphia, 1909; died in the Baptist Hospital, Memphis, Tenn., November 13, aged 61.

Lubie G. Colley, Farmington, Ky.; University of Louisville Medical Department, 1897; member of the American Medical Association; died November 1, aged 71.

Olive Jerome Crawford, Los Angeles; College of Physicians and Surgeons, Los Angeles, 1913; died November 2, aged 66.

Ralph P. Cummings, Conway, Ark.; Meharry Medical College, Nashville, Tenn., 1914; died October 14, aged 65, of chronic myocarditis.

Arthur Tappan Reed Cunningham, Honolulu, Hawaii; Western Reserve University Medical Department, Cleveland, 1900; member of the American Medical Association, North Pacific Surgical Association and the Washington State Medical Association; fellow of the American College of Surgeons; served on the staff of St. Luke's Hospital in Spokane, Wash.; died October 21, aged 72, of lymphatic leukemia.

Percy William Mark Curry, Cleveland; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1916; served with the Royal Army Medical Corps during World War I; on the staff of the Hawthornden State Hospital, Macedónia, Ohio; died in South Euclid November 20, aged 55, of carcinoma.

Byron Daniel ⊕ Sardis, Ga.; University of Georgia Medical Department, Augusta, 1900; died in Augusta in November, aged 70.

John Calhoun Davidson, Bryan, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1886; died November 4, aged 85.

James Joseph Derwin ⊕ Winsted, Conn.; Georgetown University School of Medicine, Washington, D. C., 1930; interned at St. Francis Hospital in Hartford; died in Boston September 9, aged 41, of septicemia.

George Washington Desrosier ⊕ Colusa, Calif.; Cooper Medical College, San Francisco, 1894; county physician; served as city and county health officer; on the staff of the Colusa Memorial Hospital; died October 25, aged 72, of heart disease and arteriosclerosis.

Charles G. Dick, Elwood, Ind.; Keokuk (Iowa) Medical College, 1895; died in Indianapolis November 25, aged 79, of hypostatic pneumonia.

Henry Charles Eichacker, Brooklyn; Long Island College Hospital, Brooklyn, 1914; member of the American Medical Association; past president of the Medical Society of Queens County; president of the Queensboro Surgical Society; member of the Brooklyn Gynecological Society; on the staffs of the Lutheran Hospital in Brooklyn and the Queens General Hospital in Jamaica; consultant to the Rockaway Beach (N. Y.) Hospital; died November 4, aged 54, of arteriosclerotic heart disease.

Gabriel M. Epstein ⊕ Philadelphia; Temple University School of Medicine, Philadelphia, 1929; on the staffs of the Philadelphia General, St. Luke's and Children's hospitals; interned at the Mount Sinai Hospital, where he was a member of the staff and where he died November 1, aged 41, of carcinoma.

Earl Fairbanks, Luther, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1888; served as state senator and mayor; on the staff of the Mercy Hospital and Sanitarium in Manistee; died in Kalamazoo November 16, aged 85, of myocardial degeneration.

Floyd F. Farnsworth, Milton, W. Va.; Maryland Medical College, Baltimore, 1904; member of the American Medical Association; major, medical corps, U. S. Army, during World War I; affiliated with the U. S. Public Health Service from 1919 to 1923; for many years a member of the state board of medical examiners; first president and formerly director of the bureau of venereal diseases, state board of health; served as mayor of Milton; died January 2, aged 76, of heart disease.

Manning Cromwell Field, Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1916; member of the American Medical Association and the American Academy of Pediatrics; specialist certified by the American Board of Pediatrics, Inc.; served during World War I; attending pediatrician at the Brooklyn Hospital and visiting pediatrician at Cumberland Hospital; died November 29, aged 54.

Percy Coupland Fisher ⊕ Ridgewood, N. J.; University of Vermont College of Medicine, Burlington, 1921; past president of the Ridgewood Medical Society; served during World War I; member of the courtesy staff of St. Joseph's and Paterson General hospitals in Paterson and the Hackensack (N. J.) Hospital; died in the Presbyterian Medical Center, New York, November 28, aged 51, of peritonitis following duodenal ulcer.

Thomas J. Gaffney, Lakeville, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1897; died in November, aged 76, of nephritis.

William Gauch, Newark, N. J.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1895; member of the American Medical Association; fellow of the American College of Surgeons; served during World War I; attending gynecologist and past president of the medical staff of the City Hospital; director of clinic, gynecologic department, Newark City Dispensary; on the staffs of St. James, Presbyterian and St. Michael's hospitals; died November 13, aged 72, of cerebral thrombosis and arteriosclerosis.

James Philip Goray ⊕ Fitchburg, Mass.; Harvard Medical College, Boston, 1891; specialist certified by the American Board of Ophthalmology; for many years member of the city school committee; on the staff of the Burbank Hospital; died November 12, aged 78, of arteriosclerosis and bronchopneumonia.

Arthur Rogers Grant, Utica, N. Y.; New York University Medical College, 1897; served overseas during World War I; fellow of the American College of Surgeons; for many years on the staff of the Utica Memorial Hospital; died in Pasadena, Calif., November 6, aged 73, of coronary thrombosis and generalized arteriosclerosis.

James Lonas Hardin, Sacramento, Calif.; Cooper Medical College, San Francisco, 1893; died November 18, aged 78, of coronary occlusion.

James Harkins Sr., Mount Pleasant, Pa.; Eclectic Medical Institute, Cincinnati, 1886; also a druggist; served as an officer in the Pennsylvania National Guard; veteran of the Spanish-American War; formerly county coroner, member of the borough council and school board; died in the Henry Clay Frick Memorial Hospital October 30, aged 82, of injuries received when he was struck by an automobile.

Charlton Sidney Harris ⊕ Indian Rocks, Fla.; Birmingham Medical College, 1914; served overseas during World War I; formerly physician for the Republic Steel Corporation in Sayreton, Ala.; died in the Veterans Administration Facility, Bay Pines, November 13, aged 60, of acute anemia and gastric hemorrhage due to ulcer.

William Mathias Hoel, Los Angeles; University Medical College of Kansas City, Mo., 1906; served in France during World War I; died October 28, aged 63, of coronary thrombosis.

John Henry Hohnstedt ⊕ Fort Thomas, Ky.; University of Louisville Medical Department, 1908; served during World War I; on the staffs of the St. Elizabeth and Booth Memorial hospitals in Covington and Speer's Memorial Hospital, Dayton, where he died October 28, aged 72, of coronary occlusion.

Evan Marshall Hutchins, North Wilkesboro, N. C.; North Carolina Medical College, Davidson, 1896; member of the American Medical Association; died October 30, aged 75.

Walter Kleberg ⊕ Galveston, Texas; University of Texas School of Medicine, Galveston, 1906; served as health officer of Galveston, died in November, aged 64.

Leon M. Kysor ⊕ Hornell, N. Y.; University of Buffalo School of Medicine, 1903; served as president of the Lake Keuka Medical and Surgical Association; veteran of the Spanish-American War and World War I; on the staffs of the Bethesda Hospital and St. James Mercy Hospital, where he died October 17, aged 73, of congestive heart failure and uremia.

Kathryn Rose Lavin, Flint, Mich.; Loyola University School of Medicine, Chicago, 1932; member of the American Medical Association; on the staffs of the Women's Hospital, Hurley Hospital and St. Joseph's Hospital, where she died October 21, aged 47, of carcinoma of the ovaries.

Frank Robert Lee ⊕ North Andover, Mass.; Tufts College Medical School, Boston, 1927; interned at the Lawrence General Hospital in Lawrence; died October 15, aged 41, of coronary thrombosis.

Marion Bates Leverett ⊕ McGehee, Ark.; University of Arkansas School of Medicine, Little Rock, 1934; interned at the Little Rock City Hospital, Little Rock, where he served a residency; on the staff of the Dermott Hospital in Dermott; died October 19, aged 36, of injuries received in an automobile accident.

Gomer S. Llewelyn ⊕ Mayview, Pa.; Chicago College of Medicine and Surgery, 1912; superintendent of the Mayview State Hospital; died in St. Margaret Memorial Hospital, Pittsburgh, November 21, aged 59, of cancer of the left kidney.

Thomas Ignatius Lynch ⊕ Louisville, Ky.; University of Louisville School of Medicine, 1925; died in the SS Mary and Elizabeth Hospital November 9, aged 45, of hypertensive heart disease.

John Malcolm MacLeod ⊕ Quincy, Mass.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1906; served as school physician and as city physician; for many years on the staff of the Quincy City Hospital; died October 19, aged 72, of coronary occlusion.

James Durant Macon, Meridian, Miss.; Meharry Medical College, Nashville, Tenn., 1912; died September 26, aged 62, of lobar pneumonia.

Frank T. Marr ⊕ Chillicothe, Ohio; College of Physicians and Surgeons, Baltimore, 1901; died October 28, aged 68, of cerebral hemorrhage.

Charles Summers Marsden ⊕ San Diego; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1903; died October 13, aged 72, of carcinoma of the cecum.

Emit Luther McCafferty, Mount Vernon, Ala.; Atlanta College of Physicians and Surgeons, 1902; member of the American Medical Association and the American Psychiatric Association; in 1939 a citation was voted to him by the Medical Association of the State of Alabama for early attempts at production and transmission of pellagra in 1907-1908; affiliated with the Searcy Hospital; died in an infirmary in Mobile, January 14, aged 68.

William James McCausland ⊕ Quincy, Mass.; Harvard Medical School, Boston, 1900; fellow of the American College of Surgeons; physician to the city board of health; member of the consulting staff of the Quincy City Hospital, where he died November 5, aged 70, of cerebral hemorrhage.

William Kenneth McCoy, Gum Spring, Va.; Medical College of Virginia, Richmond, 1900; died October 30, aged 72, of encephalitis.

Rogers William McKean ⊕ Fort Worth, Texas; Fort Worth School of Medicine, Medical Department of Texas Christian University, 1917; died in the Gladewater Hospital, Gladewater, October 7, aged 57, of cirrhosis of the liver.

Frank E. McKim ⊕ Marietta, Ohio; Medical College of Ohio, Cincinnati, 1884; life member of the Ohio State Medical Association; died October 20, aged 84.

Hugh Clark McRee, Hartselle, Ala.; University of Nashville (Tenn.) Medical Department, 1898; member of the American Medical Association; formerly engaged in special work under the supervision of the bureau of preventable diseases of the state department of health; served as health officer of Lee and Marion counties; died in St. Vincent's Hospital, Birmingham, October 7, aged 69, of ruptured aneurysm of the abdominal aorta and generalized arteriosclerosis.

Jouett Menefee, Bonita Springs, Fla.; University of Louisville (Ky.) Medical Department, 1906; died October 26, aged 65, of mesenteric thrombosis.

Nelson B. Michael, Belington, W. Va.; Maryland Medical College, Baltimore, 1904; on the staff of the Tucker County Hospital, Parsons, where he died October 28, aged 70, of hypertensive heart disease with nephritis.

Caroline I. Peterson Mitchell, Orange, Texas; (licensed in Texas under the Act of 1907); died October 3, aged 72.

George Andrew Moore ⊕ Palmer, Mass.; College of Physicians and Surgeons, Boston, 1910; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; on the staffs of the Monson State and Wing Memorial hospitals; died October 6, aged 74, of arteriosclerotic heart disease.

Edgar L. Morrill ⊕ Fort Collins, Colo.; John A. Creighton Medical College, Omaha, 1902; charter member and past president of the Larimer County Medical Society; served during World War I; eye, ear, nose and throat consultant for the county draft board during World War II; consultant in eye, ear, nose and throat to the Larimer County Hospital; died January 19, aged 69, of coronary thrombosis.

Andrew Nelson, Iron Mountain, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1900; died in the Veterans Administration Facility, Bay Pines, Fla., October 25, aged 75, of hypertensive heart disease.

Evertt Allen Oliver ⊕ Richland, Mo.; Marion-Sims-Beaumont Medical College, St. Louis, 1902; also a graduate in pharmacy; on the staff of the Waynesville (Mo.) Hospital; died October 6, aged 72.

Richard Willis Oliver, Louisville, Ky.; Louisville National Medical College, Medical Department State University, 1903; member of the staff of the Red Cross Hospital; died in Danville, Va., September 15, aged 70.

Sidney Nuttall Parkinson ⊕ Piedmont, Calif.; University of Pennsylvania School of Medicine, Philadelphia, 1926; interned at the Knickerbocker Hospital and the Manhattan Eye, Ear and Throat Hospital, both in New York; member of the Pacific Coast Oto-Ophthalmological Society; began active duty as a lieutenant commander in the medical corps of the U. S. Naval Reserve on July 18, 1942 and service terminated in June 1943; specialist certified by the American Board of Otolaryngology; died October 31, aged 46, of carcinoma of the lung.

Carl Richard Peterson ⊕ Chicago; Jenner Medical College, Chicago, 1906; Bennett Medical College, Chicago, 1913; died in Thomasville, N. C., November 7, aged 70, of cardiovascular disease.

Francis Xavier Pidgeon, New York; Albany (N. Y.) Medical College, 1896; served during World War I; for many years had been on the medical staff of the New York Central Railroad; died in the New York Post-Graduate Hospital October 31, aged 72.

Frances Elizabeth Potter, Upper Darby, Pa.; Temple University School of Medicine, Philadelphia, 1932; member of the American Medical Association; served on the staff of the Norristown State Hospital in Norristown; died November 3, aged 50.

tions to be noted are 2 instances of temporary albuminuria, 2 of urticaria, 2 of abscesses, 1 of dermatitis and 10 of transient stomatitis. This success with bismuth is more significant as arsenic resistance increases. Up to 16 per cent of the cases treated in a Lyons dermatology clinic have been resistant to arsenic compounds.

STOCKHOLM, Jan. 15, 1946.

Seventy-Six Grants for Research in Medicine

On December 7 considerable sums of money were granted by the Therese and John Andersson Foundation to seventy-six medical research workers and institutions. The largest amount, 7,000 kronor, was given to Dr. L. Engstrand of Stockholm for research into intra-abdominal blood circulation with special reference to the portal blood and oxygen supply of the liver and its relation to the function of the liver under certain surgical conditions. Large sums were granted for research in a study of blood-building factors by Dr. G. Ågren of Uppsala University, a study of hypertension by Dr. P. Edman of Stockholm, a study of the importance in coronary diagnosis of heart function tests, particularly the hypoxemia test, by Dr. G. Nylin of Stockholm, a study of the toxic and therapeutic effects of dextran, the blood plasma substitute, by Dr. G. Thorsén of Stockholm, an investigation of the production of sexual hormones by the adrenal glands by Dr. Miriam Furuhjelm of Stockholm, an investigation by Dr. J. Agner of Stockholm of the formation and significance of verdoperoxidase, a study of the respective roles of the respiratory center and the peripheral chemo receptors in acclimatizing to oxygen deficiency by Dr. H. Bjurstedt of Stockholm, a study of osseous development in infancy by Dr. B. Malmgren of Stockholm and a study by Dr. E. Wassén and Dr. G. Zander of the effect of dicumarol on experimentally produced arthritis and other inflammatory conditions.

Swedish Hospital in Poland

In the little Polish town of Otwock, a few miles southwest of Warsaw, Swedish money and effort are combining to build a hospital to help relieve the suffering of Poland. The hospital consists of thirty-two buildings, it has beds for 300 patients, and it will cost about 3 million kronor. It is to be primarily a tuberculosis hospital but will also have a general medical division. Every bit of material for the actual building as well as the equipment and medicines have been sent from Sweden. Swedish engineers are directing the construction of the buildings and Swedish doctors the medical aspects of the project. In January a completely equipped tuberculosis dispensary, including the latest types of x-ray apparatus, left Stockholm headed by Dr. H. Neumüller, a specialist in this field. With him were a pediatrician, a nurse and an x-ray technician. A Polish tuberculosis specialist, Polish nurses and office help will assist Dr. Neumüller. The Swedes plan to run the hospital for a year and then turn it over to the Poles for future work.

Heavy Carbon Produced in Sweden

When news of the success of American scientists in producing heavy carbon reached Sweden, it was revealed that at the Wennergren Institute investigators have been working on this problem for several years and have also been successful in producing carbon 13. According to Professor John Runnström, the Swedish scientists built their apparatus according to the method developed by the American Nobel Prize winner Harold C. Urey and were able to produce small quantities of the substance. This led to investigations into albumin synthesis of micro-organisms. Unfortunately there is not as yet a mass spectrometer in Sweden, so that it has been necessary to forward preparations to the United States for analysis. However, this type of spectrometer is now being built and is expected to be ready in the near future.

Courses for "Sports Physicians"

The critical attitude of Swedish physicians has been evidenced in one of the greatest popular movements of this age, athletics. Because the physicians have refused to maintain that sports prolong life or protect from illness they have been accused of obstructing the progress of sports and of indifference to improving the health of the public. The result has been the development of quackery in connection with the physiology of athletics, training methods, diet and so on. Last year saw the development of closer cooperation between physicians and the sports movement, and far less indifference in Sweden. An important milestone was the opening of a so-called sports clinic at the Stockholm stadium in 1944, where a continuous control has been kept on athletics. Another measure of importance is the "ski doctors" course held during the winter at Storlien, the Swedish ski resort. In June 1945 the first summer course for doctors interested in athletics was held at the Athletic College at Bösön, Stockholm. The opening session was attended by fifteen pioneering physicians representing all ages and categories, from beginners to older army doctors. Those taking part in the course participated in most of the sports themselves, receiving instruction from experts in each field on training, exercising, diet and theory. Lectures were held on medical problems in athletics, especially heart ailments. There was discussion concerning problems connected with the medical care of athletes and those indulging in sports in general. The course was pronounced a success, an enterprise to be continued and broadened.

Increase of Syphilis in Sweden

In Sweden as in all other countries the incidence of venereal disease has increased in recent years. Formerly Scandinavia had an excellent record in this respect, but the war has had its effect here also. A recent report disclosed that from 1940 to 1943 the number of cases of gonorrhea in Sweden doubled, with about 20,000 new cases. In 1945, however, there were 15,590 cases, a decrease of about 4,000 from the previous year. This decrease is probably due to the new methods of treatment, including sulfonamides, fever and penicillin.

Since 1941 the number of cases of syphilis has increased fivefold, the figure in 1944 being 1,310 new cases, with even more in 1945. The Swedish health authorities are using arsphenamine and heavy metal salts in their treatment of syphilis and feel that Americans are overoptimistic on the basis of too little experience with penicillin to justify abandoning the older methods. Penicillin is used only when the orthodox treatment is not possible.

Large Donation to Institute for Cytologic Research

Professor Torbjörn Caspersson, chief of the Swedish Institute for Cytologic Research, has announced that the institute has received a gift of 336,000 kronor for a new building at the Karolinska Hospital in Stockholm. Although it has been doing remarkable work in cell research, the institute has been carrying on in rather primitive and cramped quarters; the new building will permit a larger staff and greater activity. Professor Caspersson has recently returned from a three months trip to the United States, where he had been invited by an organization for cancer research to take part in its convention and to report on his own work.

Swedish Physician to Lecture in the United States

Dr. Gunnar Bauer, who has achieved international recognition because of his heparin treatment for thrombosis, has been invited by American physicians to lecture in the United States. He plans to leave at the beginning of February and remain in the United States for about two months; then, at the invitation of the Danish Surgical Association, he will lecture on his treatment in Copenhagen.

Gonococcus Culture

According to a recent resolution of the Swedish parliament, any doctor may now requisition culture tubes from various bacteriologic laboratories and after taking a specimen submit it for analysis at the government's expense. From the northern part of the country, where there are no laboratories, the specimens are flown to Stockholm within twelve hours.

Unusual Operation by Stockholm Physician

Dr. Clarence Crafoord, chief of the Sabbatsberg Hospital in Stockholm, recently performed for the sixth time an operation for which he is receiving a good deal of recognition. He has operated on the aorta in cases of "coarctatio aortae" and has been extremely successful.

BRAZIL

(From Our Regular Correspondent)

Rio de Janeiro, Dec. 31, 1945.

Hyperthyroidism and Goiter

Dr. Mariano de Andrade and Dr. Raymundo Britto have published a review covering a ten year period during which they treated 900 patients with thyroid disease, of whom 563, or 62.5 per cent, had manifestations of hyperthyroidism. Predominant among the thyroid diseases without toxicity were puberty goiter (87 cases, or 9.7 per cent), the adenomas (72 cases, or 8.0 per cent) and nontoxic nodular goiter (59 cases, or 6.5 per cent). A simple analysis of the cases disclosed that 96.6 per cent of the patients with hyperthyroidism presented goiter, while toxic forms without definite enlargement of the thyroid occurred in 3.4 per cent. Among the patients with toxic goiter the diffuse form was present in more than half (53.7 per cent), or 51.7 per cent of all the patients presenting hyperthyroidism. In the class of diffuse toxic goiter the authors included exophthalmic goiter (Basedow-Graves syndrome). Of 293 cases which were specially studied 170, or 58.0 per cent, showed all degrees of exophthalmos. The exophthalmos was bilateral in 162 patients (95.3 per cent), unilateral in the left eye in 6 (3.5 per cent) and in the right eye in 2 (1.2 per cent). The number of cases of hyperthyroidism was unevenly divided between the two sexes, 84.9 per cent in women, when all the forms of the disease were taken into consideration. Predominance in women was still higher (94.7 per cent) when thyrotoxicosis was considered alone. Andrade and Britto emphasized the point that the color distribution was very significant, since 81.9 per cent of the patients were white. However this does not allow for the difference in the distribution of color in the population, from which the patients may represent a peculiar sample. The largest number of patients were from 20 to 40 years of age, particularly between ages 25 and 35. Hyperthyroidism was not common before age 10 or after 60. Of the 900 patients studied 377, or 41.9 per cent, were treated surgically; 375, or 41.7 per cent, were treated medically; 6, or 0.7 per cent, were treated by x-rays, and 142, or 15.8 per cent, refused any treatment. The deaths were 13 in all, 9 of them after operations.

In another paper, A. A. Sampaio presented the results of the goiter survey which he made over a period of several years in a sample of sixteen counties of the state of São Paulo, especially in the school population. He found a total of 16,843 cases of the disease. There are extensive districts where the incidence is between 20 and 30 per cent, but particular areas in the high plateau region have an incidence of 70 and even 80 per cent. In a general manner the incidence steadily increases with age. The disease in the state of São Paulo has decreased in the last hundred years. The author believe that this is due to improvement in health conditions of the general population which accompanied the improvement in economic conditions. Sampaio points out that the extension and the intensity of the disease in many counties of the state should lead the authorities to an attempt to remedy this situation.

A. L. Pereira published the results of an experiment carried out during the last two years with the use of iodized table salt in areas of endemic goiter in the state of Minas Gerais. He says that, from a general average of 44 per cent, the incidence decreased to an average of 27 per cent.

Special Medical Courses

A series of lectures under the general title of "Recent Progress of American Medicine," sponsored by Dr. Beatrice Berle, wife of the United States ambassador to Brazil, has been organized at the center of medical studies of the Misericordia Hospital of Rio de Janeiro. These lectures are being delivered by Brazilian alumni of American universities. The course, to be completed during the month of December, includes lectures on recent advances in the serology and treatment of syphilis (Dr. A. Severo da Costa), cardiology (Dr. A. Araujo Villela), nutrition (Dr. Benjamin Albagli), gastroenterology (Dr. E. Figueiredo Mendes), orthopedic surgery (Dr. Henrique de Gois), urology (Dr. Paulo de Albuquerque), anesthesia (Dr. Oscar V. Ribeiro), pediatrics (Dr. Luis T. Barbosa), otorhinolaryngology (Dr. Waldemar Salem) and allergy (Dr. Ulysses F. Alves).

Dr. Flavio A. de Souza, associate professor of clinical psychiatry at the University of Rio de Janeiro, is now giving a special course on the principal subjects of psychosomatic medicine. Dr. Mira y Lopez of Barcelona, Spain, will deliver a lecture included in the course on the subject "Psychosomatic Medicine versus Integral Medicine."

Personal

Dr. Raul Leitão da Cunha, professor at the School of Medicine of the University of Rio de Janeiro and president of the university for several years, has been appointed minister of health, succeeding Hon. Gustavo Capanema, who held this post for more than ten years during the administration of President Getulio Vargas.

Dr. Hugo Pinheiro Guimarães has been appointed dean of the Medical School of the University of Rio de Janeiro, succeeding Dr. Froes da Fonseca.

Dr. Roberval C. de Farias has been appointed director general of the National Department of Health, succeeding Dr. J. de Barros Barreto, who had held the post since 1942.

Dr. J. Velho da Silva has been appointed secretary general of health of the Federal District (city of Rio de Janeiro), succeeding Dr. A. de Oliveira Lima, who had occupied this post since March of last year. The secretary of health has under him the Department of Hospitals and the Department of Public Health.

Marriages

John Lippincott Guerrant, Callaway, Va., to Miss Laura Elizabeth Bailey of McConnellville, S. C., in Charlottesville, November 30.

Thomas Joseph Murphy, Columbus, Ohio, to Miss Elaine McKinney of Waverly, Ala., at Rossville, Ga., October 13.

Marion Calvin Martin, Miami, Fla., to Mrs. Elizabeth Purse Clinton of Chattanooga, Tenn., December 13.

Alva Richard Taylor, Fort Lauderdale, Fla., to Dr. Garland Marian Johnson of Jackson, Tenn., September 29.

Paul Ward Robinett, Huntington, W. Va., to Miss Shirley Harwood Kersey of Richmond, Va., December 31.

Karl Crawford Jonas, Marion, N. C., to Mrs. Bonnie Babcock Brooks in Philadelphia, November 24.

Robert E. Stowell, St. Louis, to Miss Eva Mae Chambers in Jacksonville, Ill., December 1.

James J. Ledgard Jr., Maynard, Mass., to Miss Dana Lee Catt of Brooklyn, October 4.

Anne Louise Hendricks, Fort Lauderdale, Fla., to Mr. Robert McCurdy recently.

Jack M. Levin, Atlanta, Ga., to Miss Adele Segall of Miami, Fla., October 18.

Correspondence

CORONARY OCCLUSION AND THROMBOSIS AND MYOCARDIAL INFARCTION

To the Editor:—The discussion by Blumgart, Boas and others and by Master regarding the effect of effort on the incidence of coronary occlusion, coronary thrombosis and myocardial infarction shows the need of more precise use of these terms.

Blumgart (THE JOURNAL, July 14, 1945, p. 775) contributes a report on the relation of effort to "attacks" of acute myocardial infarction as he saw it in army training camps. Acute myocardial infarction does not occur as an "attack" per se but is a result of sudden deprivation of an area of heart muscle of its blood supply by occlusion of the main supplying artery or a sufficient number of its branches. Arteriosclerosis is generally the underlying cause of the narrowing of the artery, but this is never a sudden process. The occlusion caused by atheromatous intimal thickening may reach a point where a slight increase in myocardial effort will result in cardiac collapse. This, however, does not necessarily include anemic infarction unless a state of anemia exists in the area and for a sufficient time. This can be accomplished quickly by the addition of thrombotic elements to an atheroma, completely sealing off an already greatly narrowed lumen. Sudden hemorrhage into an atheroma during the systolic rise involved in sudden severe effort might conceivably result in complete arterial block, but in the course of careful gross and microscopic study of infarcted hearts in a period of twenty-five years this intra-atheromatous hemorrhage has rarely impressed me as sufficient to produce complete arterial occlusion.

"Coronary thrombosis" has a fairly definite meaning to the internist, with its suddenness, the severe pain, the obvious collapse of ventricular power, and in addition the electrocardiographic picture. To the pathologist there is no thrombosis unless an actual thrombus is demonstrable. How long does it take for a thrombus to form in an organ like the heart which is shaking itself in systole and diastole 100 to 150 times a minute during strenuous work or exercise? No one knows. Presumably it will not develop at all when (1) the arteries are normal or (2) the current of the blood stream is not excessively slowed. However, assuming that an atheroma has been formed in the course of time near the base of a main stem coronary artery and following extension of the degeneration so as to injure the intima a partially occluding thrombus has been laid down at this point, what might be the effect of sudden severe effort on the ability of the thrombus to stay put? I think I have proved satisfactorily in a few cases that such a thrombus has been torn loose at the time of the exertion and forced distally about 0.5 cm. to occlude completely the anterior descending branch of the left coronary artery, resulting in anemic infarction. This proof of the relation of exertion to myocardial necrosis is rarely obtained because of a common technical error in postmortem dissection of the heart. The usual insertion of a scissors blade into the mouth of an artery and cutting distally will disclose the thrombus but often at a point beyond the former site of the clot, because it is apt to be pushed forward out of its original position. Careful removal of the "roof" of the artery by lifting a longitudinal wedge will disclose the clot in situ vero. I described this method in the *Transactions of the American Clinical and Climatological Association* for 1932 in an article by L. W. Gorham and others.

It is of great immediate importance that medical experts show more unanimity on such a basic matter as the effect of exertion on the arteriosclerotic heart. Compensation courts daily hear statements that a claimant while lifting a heavy object felt a severe pain in his midchest, collapsed and in an hour was dead, with autopsy showing cardiac infarction, old atheromatous arterial narrowing and fresh coronary thrombosis. The expert on the opposite side may swear that there is no relation between the heavy lifting and the cardiac collapse. The referee is more inclined to accept a causal relationship between the exertion and the fatality and, in my opinion, is more apt to be right than wrong. Rest and not exertion is the basic component of cardiac therapy. While compensation courts with the greatest self assurance have settled to their own satisfaction the cause of cancer as related to trauma, I think they are on sound ground generally in insisting that excessive exertion has a bad effect on the arteriosclerotic heart. The fact that coronary occlusion can occur during sleep (when the systolic pressure is normally at its lowest ebb) does not in the least invalidate this principle.

The term "coronary occlusion" as the internist has come to employ it does not convey any idea of its cause. An artery can be occluded in many ways, for instance by intimal sclerosis or atheroma, which requires years or at least months, by thrombosis, which can be relatively sudden, or by embolism, which is the most sudden of all. Master assumes that coronary occlusion can be caused only by arteriosclerosis, but he is contradictory when he speaks of ". . . the hundreds of cases that the cardiologist has had in which coronary occlusion transpired during sleep, rest or mild and usual activity." (THE JOURNAL, Sept. 1, 1945, p. 90). It takes many sleeps indeed to produce arteriosclerotic occlusion.

VICTOR C. JACOBSEN, M.D., Troy, N. Y.

CAFFEINE WITH SODIUM BENZOATE FOR ACUTE ALCOHOLISM

To the Editor:—At the psychiatric division of Professors Wagner Jauregg and Poetzel in Vienna in 1937 and at the admitting room of St. Joseph Hospital from 1940 to 1945 I had the opportunity of studying alcoholism in its various manifestations. Ordinarily we used to resort to paraldehyde, restraints and seclusions for the disturbed resistive violent alcoholic addict, and we used to give various stimulants for the patient in an alcoholic coma. For the last two years we have not admitted acute alcoholic addicts to the wards of St. Joseph Hospital in Paterson, N. J., except patients in deep coma complicated by respiratory failure.

Immediately after arrival in the emergency room every alcoholic addict either violent or in coma received 15 grains (1 Gm.) of caffeine with sodium benzoate intravenously, the rate of injection being about ten seconds. The administration of caffeine with sodium benzoate to these patients was followed by improvement in the clinical state in forty-five seconds. Such improvement manifested itself in the arousal of the comatose patients in forty-five seconds and sedation of the excited group due to general stimulation of the central nervous system and inhibitory centers.

FRITZ F. ADLER, M.D., Paterson, N. J.

AMYELOIDEMIA VS. AGRANULOCYTOSIS

To the Editor:—Since the term "agranulocytosis" chosen by W. Schultz for the syndrome of diminished leukocytes in the blood means in its strict sense an increase in the nongranular leukocytes, it appears that a better term is necessary to designate this medical entity.

Neutropenia is displacing the term granulocytopenia, which may occur in a mild or severe form with angina. It may be wise for clarity to substitute the term amyeloidemia for agranulocytosis when it refers to a complete absence of the myeloid series of white cells in the blood. Since all the cells of the myeloid series are involved in this syndrome the coined terms of aneutremia or aneutrophilemia, signifying the absence of neutrophils in the blood, is not warranted.

The term amylemia, referring to the presence of hypothetical starch in the blood, appears in Stedman's Dictionary. The possible presence of amyloid in the blood, amyloidemia, is a similar potential word. These are distinguishable by spelling and pronunciation from amyeloidemia.

BERNARD SELIGMAN, M.D., Brooklyn.

Bureau of Investigation

CEASE AND DESIST ORDERS

Abstracts of Certain Federal Trade Commission Releases

The work of the Federal Trade Commission in helping to protect the public against misrepresentation or fraud in the medical as well as other fields, has been greatly extended by the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act. The Food, Drug and Cosmetic Act of 1938 increased the Food and Drug Administration's control of the advertising claims and statements made on the label of a medicine or on the carton or in the accompanying leaflet, whereas what might be termed collateral advertising, that which appears in circulars, newspapers and magazines and over the air, comes more actively under the purview of the Federal Trade Commission by virtue of the Wheeler-Lea Amendment.

THE JOURNAL has at various times commented on the activities of the Federal Trade Commission in this connection, even before the Wheeler-Lea Amendment gave it its added powers. In some cases the Commission may accept from the person or concern involved a stipulation that the objectionable practices or claims cited will be discontinued. In other cases the Commission issues what is known as a Cease and Desist Order, in which the individual, manufacturer or distributor cited is ordered to cease and desist from practices which have been declared objectionable. In some cases the claims cited have been discontinued by the firms several months (or even longer) before the issuance of the order. Abstracts of some of the orders issued in 1943, 1944 and 1945 follow in this form: name of product, name of distributor, date of issuance of complaint, date of issuance of Cease and Desist Order and terms of order.

Allmentone.—Thomas E. Collins, trading as Thomas E. Collins Company, San Francisco; complaint issued August 24, 1942; order issued Nov. 1, 1943. Order directed the respondent to cease representing that his product expels mucus from the body, affords relief for catarrhal conditions generally, aids in fortifying mucous membranes against infection, possesses any value in the treatment of inflammation of the mucous membranes, eliminates toxic substances or deposits from the body, or is a cure or remedy for colds The findings were that the preparation is composed of powdered wheat embryo, powdered dried skim milk and vegetable concentrates, and that though it may have some food value, it is wholly without effect as a therapeutic agent.

Cuproloid.—Charboy Products, Inc, Red Bank, N. J.; complaint issued May 7, 1942, order issued Jan 24, 1944 Order directed the concern to discontinue any advertisements which represented product as being of value in treatment of, or constituting a cure or remedy for pimples, acne, surface ulcers, burns, poison ivy, athlete's foot and some other skin disorders, or possessing sterilizing or healing properties, keeping the skin healthy, being approved by competent medical authorities or prescribed by the medical profession.

McFadden 3 Sisters Springs Mineral Waters.—Roy A. Whipple and Mrs. Ruth Carter Whipple, trading as McFadden 3 Sisters Springs, Hot Springs National Park, Ark; complaint issued April 17, 1943; order issued Dec. 7, 1943 Order directed the respondents, who reside in Winnetka, Ill, to discontinue advertisements representing that their waters or any other products of substantially similar composition will eliminate poisons from the system to any significant extent, or will be effective in removing excess acids and impurities through the kidneys and bladder, that the use of these waters will maintain a proper balance of minerals in the body or that any of the waters is a cure or remedy for the various ailments and diseases enumerated in the advertisements. These consisted of more than twenty, and included arthritis, neuritis, Bright's disease, diabetes, anemia, nervous prostration, high or low blood pressure, gallstones and sinusitis.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS
EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Board in Specialties were published in THE JOURNAL, Feb. 16, page 445.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Mar. 19 21. Sec. Dr. B. F. Austin, 519 Dexter Ave., Montgomery 4.

ALASKA: Juneau, March 5. Sec, Dr. W. M. Whitehead, Box 140, Juneau.

ARIZONA:* *Examination.* Phoenix, April 2 3 *Endorsement.* Phoenix, April 6 Sec, Dr. J. H. Patterson, 826 Security Bldg, Phoenix.

ARKANSAS:* *Medical* Little Rock, June 6 7. Sec, Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana *Eclectic.* Little Rock, June 6 Sec, Dr. C. H Young, 1415 Main St, Little Rock.

CALIFORNIA: *Written* Los Angeles, March 11-14. Sec, Dr. Frederick N. Scatena, 1020 N St, Sacramento 14.

COLORADO:* Denver, April 2 5. Final date for filing application is March 18. Sec., Dr. J. B Davis, 831 Republic Bldg, Denver.

CONNECTICUT.* *Medical Examination.* New Haven, March 12-13. *Endorsement* New Haven, March 26 Sec to the Board, Dr. Creighton Barker, 258 Church St, New Haven. *Homeopathic.* Derby, March 12 13. Sec, Dr Joseph H. Evans, 1488 Chapel St, New Haven.

DELAWARE: *Examination* Dover, April 9. *Reciprocity.* Dover, April 16. Sec, Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St, Dover.

DISTRICT OF COLUMBIA:* *Reciprocity.* Washington, March 11. Sec., Commission on Licensure, Dr G C. Ruhland, 6150 E. Municipal Bldg, Washington 1.

FLORIDA:* Jacksonville, June 24-25. Sec, Dr. Harold D. Van Schaik, 2736 S W. Seventh Ave, Miami 36

GEORGIA. Atlanta and Augusta, March 27-28 Sec, State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta 3

IDAHO. Boise, July 9. Dir., Bureau of Occupational Licenses, Miss Agnes Barnhart, 355 State Capitol Bldg, Boise.

ILLINOIS: *Examination.* Chicago, April 2-3. *Reciprocity.* Chicago, April 4 Supt of Registration, Department of Registration & Education, Mr. Philip Harman, Springfield.

INDIANA: Indianapolis, April 25 27. Sec, Board of Medical Registration & Examination, Dr. W. C. Moore, 301 State House, Indianapolis 4.

IOWA.* Iowa City, March 25 27. Dir., Division of Licensure & Registration, Mr. H. W. Grefe, Capitol Bldg, Des Moines 19.

KANSAS: Kansas City, March 12-13. Sec, Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. Seventh St, Kansas City 10

KENTUCKY: Louisville, March 25-27. Sec, State Board of Health, Dr Philip E Blackerby, 620 S Third St, Louisville 2.

MAINE: Portland, March 12-13. Sec, Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.

MARYLAND: *Medical* Baltimore, March 19 22. Sec, Dr. J. T. O'Mara, 1215 Cathedral St, Baltimore 1. *Homeopathic.* Baltimore, June 18-19. Sec, Dr. J. A. Evans, 612 W. 40th St, Baltimore.

MASSACHUSETTS Boston, March 12 15. Sec, Board of Registration in Medicine, Dr. H. Q Gallupe, 413 F State House, Boston.

MICHIGAN:* Detroit, March 26 28 Sec, Board of Registration in Medicine, Dr. J. E McIntyre, 100 W. Allegan St, Lansing 8.

MISSISSIPPI. June Asst. Sec, State Board of Health, Dr. R. N. Whitfield, Jackson 113.

MISSOURI *Examination* St. Louis, Feb 25 27. Sec, State Board of Health, Dr. R. M. James, State Capitol Bldg, Jefferson City.

MONTANA: Helena, April 1-3 Sec, Dr. O. G Klein, First National Bank Bldg, Helena

NEBRASKA:* Omaha, March 25 27. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg, Lincoln 9

NEW JERSEY: Trenton, June 18-19. Sec., Dr. E. S. Hallinger, 28 W. State St, Trenton.

NEW MEXICO:* Santa Fe, April 8 9. Sec, Dr. LeGrand Ward, 141 Palace Ave, Santa Fe.

NEW YORK: Jan 28 31. Sec., Dr. Jacob L. Lochner, Education Bldg, Albany.

NORTH CAROLINA: Raleigh, March 25 28. Act. Sec, Mrs. Louise J. McNeill, 226 Hillsboro St, Raleigh

NORTH DAKOTA Grand Forks, July 2 5. Sec, Dr. G. M. Williamson, 4½ S. Third St, Grand Forks.

OHIO: *Examination* Columbus. March 19 22. Sec, Dr. H. M. Platter, 21 W. Broad St, Columbus.

OKLAHOMA:* Oklahoma City, March 23. Sec., Dr. J. D. Osborn Jr., Frederick.

PENNSYLVANIA: Philadelphia and Pittsburgh, April. Act. Sec, Bureau of Professional Licensing, Department of Public Instruction, Mrs. M. G. Steiner, 351 Education Building, Harrisburg.

RHODE ISLAND: Providence, April 4 5 Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg, Providence

SOUTH CAROLINA: Columbia, Feb. 24 26. Sec, Dr. N. B. Heyward, 1329 Blanding St, Columbia.

SOUTH DAKOTA:* Pierre, July 16 17. Sec, Medical Licensure, State Board of Health, Dr. Gilbert Cottam, Capitol Bldg, Pierre.

TENNESSEE:* Memphis and Nashville, March 27-29. Sec., Dr. H. W. Qualls, 130 Madison Ave, Memphis 3.

TEXAS: Austin, March 27 29. Sec., Dr. T. J. Crowe, 918 20 Texas Bank Bldg, Dallas 2

Vermont: Burlington, March or April. Sec., Dr. F. J. Lawliss, Richford.

Virginia: * Richmond, March 25-28. Sec., Dr. J. W. Preston, 803 Medical Arts Bldg., Roanoke.

Washington: * Seattle, July 11-12. Sec., Department of Licenses, Miss Nell Adams, Olympia.

West Virginia: Charleston, April 1-3. Commissioner, Public Health Council, John E. Offner, State Capitol, Charleston 5.

Wyoming: Cheyenne, Feb. 4. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Colorado: Denver, March 6-7. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

District of Columbia: Washington, April 22-23. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington 1.

Florida: Gainesville, June 4. Final date for filing application is May 20. Sec. Dr. J. F. Conn, John B. Stetson University, DeLand.

Iowa: Des Moines, April 9. Dir., Division of Licensure & Registration, H. W. Grefe, Capitol Bldg., Des Moines 19.

Michigan: Ann Arbor and Detroit, May 10-11. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

Minnesota: Minneapolis, April 2-3. Sec., Dr. Raymond N. Bieter, 126 Millard Hall, University of Minnesota, Minneapolis 14.

Nebraska: Omaha, May 7-8. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln 9.

Oregon: Portland, March 2. Sec., Board of Higher Education, Mr. C. D. Byrne, University of Oregon, Eugene.

Rhode Island: Providence, Feb. 13. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Dakota: Vermillion, March 13-14. Sec., Dr. G. M. Evans, Yankton.

Tennessee: Memphis and Nashville, March 25-26. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis.

Wisconsin: Madison, April 6. Prof. R. N. Bauer, 152 W. Wisconsin Ave., Milwaukee 3.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Chiropodists: Authorized to Use Narcotics as Local Anesthetic.—The plaintiffs commenced the present suit, an original mandamus action, in the Supreme Court of Michigan to compel the defendants, Michigan Board of Pharmacy and Director of Drugs and Drug Stores, to issue them narcotic permits.

In 1943, prior to which chiropodists were issued narcotic permits, the attorney general of Michigan issued an opinion to the Director of Drugs and Drug Stores to the effect that there was nothing in the chiropody act giving chiropodists any right to use narcotics; that chiropodists were permitted to use "only local anesthetics such as butaline or 2 per cent novocain, evidently claimed to be non-narcotic." Plaintiffs, licensed chiropodists, accordingly filed suit in the federal court to restrain the collector of internal revenue from refusing to accept their applications for reregistration under the Harrison Narcotic Act and to compel the collector to issue special stamps as evidence of such reregistration. The district court defined local anesthetics as

> . . . anaesthetics that when locally applied produce an absence of sensation in the organ or tissue treated. Narcotics, including cocaine, other derivatives of coca leaves, and similar compounds when properly applied produce such an effect, and are used as local anaesthetics.

The district court also pointed out that the Michigan law is similar to the uniform narcotic act, adopted by a number of states, and that the attorneys general of at least six of those states have ruled that chiropodists are entitled to use narcotics thereunder. It entered a decree in favor of the plaintiffs, but this decree was reversed by the circuit court of appeals on the ground that a federal court should not undertake the interpretation of a local law without some views of the local judges familiar with the trends of local law. The present suit was then instituted.

Section 2 of the Michigan chiropody act provides that a certificate of qualification or license "shall not authorize chiropodists to amputate the human foot or toes, or to use or administer anaesthetics other than local." Section 1 of the uniform narcotic drug act, adopted by Michigan in 1937, defines a physician as "a licensed practitioner of medicine or osteopathy as defined by law in this state and any other person authorized by law to treat sick and injured human beings in this state and to use narcotic drugs in connection with such treatment."

The defendants contended that since chiropodists are not mentioned in the narcotic act, which specifically mentions physicians, it was the intention of the legislature to exclude them. This contention, said the Supreme Court, overlooks the broader definition of physician in the act, namely, ". . . any other person authorized by law to treat sick and injured human beings in this state and to use narcotic drugs in connection with such treatment." Chiropodists, the court continued, are called on to perform many operations such as removal of ingrowing nails, growths and callosities on the foot and manipulation of the bones of the foot, all of which would cause tremendous pain to the patient were anesthetics not used. The narcotic act and the chiropody act, said the court, taken together, indicate that a chiropodist may use local anesthetics. Local anesthesia is "that which is confined to one limited part of the body." It is the use of local anesthesia to which a chiropodist is restricted, concluded the court, not the agency employed to bring about such anesthesia. Accordingly judgment was entered in favor of the plaintiffs.—*Fowler v. Michigan Board of Pharmacy, 20 N. W. (2d) 680 (Mich., 1945).*

Medical Practice Acts: Revocation of License for Violation of Harrison Narcotic Act.—The plaintiff, having pleaded guilty, in the federal district court, to a violation of the Harrison Narcotic Act, was cited to appear before the defendant, Board of Medical Examiners, to show cause why his license to practice medicine and surgery should not be revoked for acts of unprofessional conduct. After a hearing, the defendant revoked the plaintiff's license. Subsequently the plaintiff filed suit in the superior court to show cause why the board's action should not be set aside. The superior court sustained the board, and the plaintiff appealed to the Supreme Court of Arizona.

The plaintiff first contended that the Board of Medical Examiners had no jurisdiction to revoke his license. He argued that the present board was created by legislation in 1935 and that it possessed only the powers set forth in the act creating it rather than the powers of the old board created in 1928 but dissolved by the 1935 enactment. The effect of the 1935 law, insisted the plaintiff, was to drop the provisions of prior laws, including the power of the board to revoke or cancel licenses. The Supreme Court quoted with approval from its decision in *Marlar* v. *Patterson*, 60 Ariz. 240, 135 P. (2d) 218, in which a similar contention was raised, as follows:

> The Medical Practice Act was amended in 1935, chapter 99, session laws of that year, and we are unable to see why the plaintiff claims that they made the board of examiners merely a board of registration. The first change made deals with the makeup of the board and the length of term each shall serve, and the second made the practice of medicine without having a valid recorded certificate a felony instead of a misdemeanor. Then there was added a section providing that every person practicing medicine, surgery or osteopathy in the state shall renew his license each year by the payment of $3 on or before January 1. Clearly these amendments had no effect whatever on the other provisions of the Medical Practice Act.

Under that decision the Supreme Court held that provisions not covered by the 1935 amendment remained in effect.

The Arizona code (Sec. 67-1106, A. C. A. 1939) provides that

> . . . Whenever a holder of a certificate is guilty of unprofessional conduct, or whenever a certificate has been procured by fraud or misrepresentation, or issued by mistake, the board shall revoke the same after citation and hearing thereon. . . .
>
> The words "unprofessional conduct" shall include . . . conviction of any offense involving moral turpitude, . . .

The Supreme Court held, as it had in *Du Vall* v. *Board of Medical Examiners of Arizona*, 49 Ariz. 329, 66 P. (2d) 1026, that a conviction under the Harrison Narcotic Act negatives any and all presumptions of good faith on the part of the defendant and brands him as a person of bad moral character, unfit to practice medicine. On the basis of these cases, therefore, the judgment in favor of the Board of Medical Examiners was affirmed.—*Garlington v. Smith, 163 P. (2d) 685 (Ariz., 1945).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1936 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Suppurating Fibromyomas: Report of Case, with Review of Literature. I. Miller.—p. 522.
Paracervical Anesthesia for Relief of Labor Pains. S. S. Rosenfeld. —p. 527.
Nonclotting Component of Postpartum Blood. E. Greenberg.—p. 532.
Primary Ovarian Pregnancy. J. F. Norton and N. M. Alter.—p. 535.
Arrhenoblastoma. D. C. Daughtry.—p. 539.
Edema of Uvula and Edema of Glottis—Reaction to Demerol-Scopolamine Analgesia. M. Steinberg.—p. 542.
Phantom Limb Syndrome Complicating Pregnancy and Puerperium. G. A. Williams—p. 546.
Erythroblastosis Fetalis in Twin Pregnancy. M. E. Aaberg and C. Roby. —p. 548.
*Reactivation of Endometriosis by Stilbestrol Therapy. R. L. Faulkner and E. A. Riemenschneider.—p. 560.

Interstitial Radium Needles for Carcinoma of Cervix.—Waterman and DiLeone report ten year survival rates in 309 cases treated at the Gynecologic Tumor Clinic at the Rhode Island Hospital, seen from 1926 through 1933 and previously reported for five year survivals. They add a new series of 198 cases which passed through the clinic from 1934 through 1938 and review the total of 507 cases, 1926 through 1938. The five and ten year survival rates for 309 cases for stage 1 carcinoma were 73 and 46 per cent respectively; for stage 2 they were 54 and 39 per cent respectively; for stage 3 they were 32 and 21 per cent; in patients with stage 4 carcinoma there were neither five nor ten year survivals. The survival rates for all stages was 35.7 per cent after five years and 24.5 per cent after ten years. For the new series of 198 cases the relative five year survival rate was 36.7 per,cent. In 1933 the use of high voltage x-rays had been instituted as part of the treatment. It soon became evident that severe reactions were occurring. A better spacing of the x-ray and radium treatment seems to have corrected this fault fairly well, so that in the years 1936 to 1938 inclusive the five year results are shown as 39.3 per cent absolute and 44.9 per cent relative survivals. The total of 507 cases had a relative five year survival rate of 36 per cent. A review of the survival rates by age groups shows that for those 45 and under the five year survival rate was 38 per cent, for those 46 and over 29.5 per cent. The good results previously reported with the use of interstitial long platinum needles of low intensity are maintained in this series and are definitely improved with the added use of x-ray therapy in the last 109 cases.

Androgen Therapy of Menopausal Symptoms in Cancer Patients.—Gusberg administered androgen to a selected group of 24 patients who had been subjected to surgery, irradiation or both for neoplastic disease or dysfunctional bleeding from the reproductive tract. The patients were given 20 mg. of methyl testosterone by mouth daily for four weeks, then 10 mg. daily for two weeks thereafter. This therapy was usually adequate to control symptoms. The vasomotor symptom of the menopause disappeared in 23 of the 24 patients. Some benefit was noted in all patients who received an adequate course of treatment. Of 12 patients who had had previous diethylstilbestrol therapy, 10 were benefited to a greater degree by the androgens. The other 2 had taken diethylstilbestrol for years and the habit was difficult to break. The percentage of menopausal women who require endocrine treatment is small; the majority of patients undergoing either a spontaneous or an artificial menopause require no treatment.

Nausea of Pregnancy Treated by Forced Hydration.—Eller and Randall employed forced hydration for the nausea of pregnancy, which they believe results from the high concentration of chorionic gonadotropin present during the first trimester. Increased elimination by the kidneys should lower this concentration below a theoretical "nausea threshold," with resultant relief of symptoms. As soon as they notice nausea the women are advised to begin drinking 4 glasses of water between breakfast and lunch, 5 glasses between lunch and supper and 6 glasses between supper and bedtime. This hydration will require getting up at night, and a glass of water should be taken each time the patient gets up. If water is vomited, the same amount should be immediately taken again. Hot water or salt water may be retained more easily. Of 68 pregnant women with symptoms of nausea and/or vomiting subjected to this treatment 32 were relieved within four days, another 10 in seven days. In the remaining 26 cases the results varied from fair to very poor.

Reactivation of Endometriosis by Diethylstilbestrol Therapy.—Faulkner and Riemenschneider report that a woman aged 36, who had severe periodic bleeding from endometriosis of the bowel requiring over seventy transfusions, was finally treated by surgical castration and was well until given diethylstilbestrol for menopausal symptoms, when severe recurrence of the bleeding took place. Permanent recovery followed discontinuance of this therapy.

Am. J. of Orthodontics and Oral Surgery, St. Louis

31:541-696 (Nov.) 1945

Albers-Schönberg Disease: 2 Cases. G. R. Winter.—p. 637.

Mandibular Lesion as First Evidence of Multiple Myeloma. T. M. Meloy, J. H. Gunter and D. A. Sampson.—p. 685.
Treatment of Fusospirochetal and Streptococcal Infections by Topical Application of Penicillin. S. L. Rosenthal.—p. 690.
*Unilateral Lacrimation Associated with Chewing. I. B. Bender.—p. 692.
Stomatitis Due to Chewing Leaves of Poison Ivy: Report of a Case. R. K. Sassaman.—p. 695.

Unilateral Lacrimation During Chewing.—Bender reports a case in which stimulation of the anterior palatine pad area only brought about congestion, lacrimation and pain. The effects were best produced by rubbing with a finger or denture pressure through food mastication. While the symptoms could be produced by reading small print and blowing the nose, the dental complaint was the more important. The pad area was definitely localized as the trigger point by the fact that unilateral biting and movements of the muscles of mastication did not reproduce the syndrome. When there is independent biting either on the right or on the left side there is no compression or rubbing on the pad area. With normal chewing the force of mastication produces a pressure because of the closeness of adaptation of the dentures on the yielding mucosal tissues. This case differs from those reported in the literature in that, associated with lacrimation, there was also congestion and pain. Whether this can be attributed to a stimulation of both the autonomic and the sensory systems is difficult to say.

Am. J. Syphilis, Gonorrhea and Ven. Dis., St. Louis

29:587-686 (Nov.) 1945

Chemotherapy of Human Filariasis with Neostibosan.—Thirty native Puerto Ricans infected with Wuchereria bancrofti were treated with neostibosan for from thirty-three to forty-eight days. All patients were given three injections of neostibosan on alternate days, the first usually containing 50 mg., the second 100 or 150 mg. and the third 300 mg. of the drug. Thereafter 300 mg. of the drug was given in single doses daily or on alternate days. Culbertson and his co-workers report that after twelve months 13 of the patients were free from circulating microfilariae and 5 others had lost from 87 to 99 per cent of their embryos, compared with the number in the blood before treatment. The 12 remaining patients showed little promise of eventual eradication of their infections after observation for nine months. Of 15 control untreated patients infected with Wuchereria bancrofti, all remained infected for fourteen months of observation. In this interval 12 showed an overall increase and 3 showed a decrease in the number of circulating microfilariae. Among the treated patients, some of whom had been free from microfilariae for twelve months, none presented untoward symptoms referable to treatment. At the end of the course of therapy little or no change had occurred in microfilaria levels of the patients. The simplest explanation for this slow loss of microfilariae is that the neostibosan does not act directly on the microfilariae but acts chiefly on the adult parasites. As a result of the death of the adult worms, the production of embryos ceases.

Leprosy in Relation to Age at Exposure.—Doull and his co-workers studied 1,520 individuals living in the province of Cebu, Philippine Islands, and exposed in the household to lepromatous leprosy. There is a clear relationship between age at time of exposure and the risk of developing lepromatous leprosy. It is highest for those exposed before the age of 5 years, decreasing progressively as the age at time of exposure increases. This is true for both males and females. The ratio of the incidence rates for males and females, for those exposed before 5 years of age, varies from 4.7:1 as rates in the age group 5 to 10 years to 1.4:1 for those 20 years and over. The average interval between exposure and development of lepromatous leprosy was 10.5 years for those exposed under 10 years of age but only six years for those exposed after the age of 10 years.

Shock in Battle Casualties.—Emerson and Ebert report studies on 112 battle casualties admitted to a field hospital with serious abdominal, chest or extremity wounds. Fifty per cent of these patients were in severe shock. The arterial blood pressure was found to provide the most reliable index of blood volume deficiency. Patients with initial systolic pressures below 85 mm. of mercury were found to have oligemia; all patients with this degree of hypotension had a diminution in blood volume that exceeded 25 per cent. A normal hematocrit reading or the demonstration of a mild anemia within a few hours after injury does not mean that severe loss of blood has not occurred. Anemia was produced by the administration of plasma to patients with severe oligemia. The majority of patients presented no evidence of an excessive loss of plasma in proportion to red cells; in a few cases with severe abdominal wounds there was demonstrated a disproportionate plasma loss, which resulted in a mild degree of erythroconcentration. Hemorrhage appeared to have been most severe in patients with extremity wounds and least severe in patients with uncomplicated chest wounds. Blood volume measurements performed preoperatively and postoperatively revealed that the average loss in 3 cases subjected to open thoracotomy was 600 cc. of blood; in 5 cases of abdominal surgery the average loss was 2,200 cc. Serial determinations of the blood volume indicated that hemorrhage occurred during the course of transfusion therapy in 11 of 23 patients studied. Plasma protein measurements before and after the injection of blood diluted with equal volumes of preservative solution indicate that retention of the latter in the blood stream is transient and of insufficient degree to produce significant hemodilution. The mortality incidence of all patients admitted in severe shock was 32 per cent; of those whose arterial pressure on admission exceeded 85 mm. of mercury, 11 per cent died within a similar period, which included the first postoperative day. The majority of deaths were attributable to penetrating abdominal wounds. Cases are described in which the clinical signs of shock were unrelieved by therapy, despite complete restoration of the blood volume to normal. The factors operative in the production of "irreversible shock" included severe infection, lesions involving the central nervous system, anoxic anoxia due to pulmonary damage and long persisting combination of anemia, oligemia and hypotension, with terminal signs of myocardial insufficiency.

Mucoepidermoid Tumors of Salivary Glands.—Stewart and his associates observed a group of salivary gland tumors differing structurally from tumors primary to these locations. They estimate the incidence of these tumors at 5 per cent of all salivary gland tumors. The material for this analysis was obtained from the Memorial Hospital (New York) records of about 700 salivary gland tumors seen between 1928 and 1943. A total of 45 cases was found. The authors divide the tumors into two histologic varieties, which they refer to as benign and malignant, but they admit that it might be preferable to speak of a "relatively favorable" and a "highly unfavorable" group. The term "benign" is scarcely ever applicable in an absolute sense and as used here does not necessarily imply innocent behavior. It does mean that thus far metastasis has not been observed from such tumors. Epidermoid metaplasia is one of the main cytologic characteristics of both classes of mucoepidermoid tumors. Whereas the basal cells are the principal type involved in this transformation, there is evidence that both mucous cells and columnar cells may undergo similar changes. The benign form of tumor is most frequent in younger and the malignant form in older persons. The most important initial symptom in benign tumors was painless swelling, but this was an initial symptom also in 8 of the 19 malignant tumors. Surgical excision and irradiation were the treatments used in these tumors. The results were favorable in patients with benign tumors, but the survival rate of the patients with malignant tumors was poor.

Nutritional Deficiency in Diabetes.—Biskind and Schreier believe that diabetes mellitus represents in the vast majority of patients impairment of hepatic response to endogenous insulin and that this results from protracted vitamin B complex deficiency. Thus the concept of insulin resistance may be extended to include most patients with diabetes. Among 94 diabetic patients studied, every one showed signs and symptoms of deficiency of factors of the B complex. Intensive and persistent oral or oral and parenteral therapy with vitamin B complex led to striking improvement in general health and often to great improvement in carbohydrate metabolism, frequently with reduction in insulin requirement or its elimination altogether.

Penicillin in Rat Bite Fever.—Brooksaler reports a case of rat bite fever due to Streptobacillus moniliformis in a girl aged 18 months. The child was treated with penicillin, and the therapeutic response to this treatment was prompt and permanent. The strain of S. moniliformis recovered was susceptible to the bacteriostatic effect of penicillin in vitro. Penicillin is recommended as the treatment of choice in rat bite and Haverhill fevers.

Congenital Atresia of Esophagus.—Lam reports 4 cases of congenital atresia of the esophagus in which surgical treatment was employed. Three of the infants are now alive and well. The low mortality in this small series may be attributed in part to the fact that the 3 infants who survived were in excellent condition at the time of operation. Pneumonia from aspiration of milk during futile attempts at feeding was prevented because an early diagnosis was made. If the anomaly is suspected, barium should not be used to demonstrate it, since this contrast medium is irritating to the bronchial mucosa. A small amount of iodized oil should be introduced through the catheter under fluoroscopic control and removed after the film has been made. The operation for the repair of atresia of the esophagus is not necessarily an emergency operation. There was a delay of three days between the diagnosis and the procedure in case 3 because of the absence of the thoracic surgeon. Even a two week interval is not incompatible with a successful result. If the diagnosis is made reasonably early, there is ample time for an infant to be taken to a surgical center where there is a competent chest surgeon.

Nontuberculous Pneumonia Complicating Pulmonary Tuberculosis.—Hogan reviews 111 cases of pneumonia complicating tuberculosis in 104 patients; 5 patients had more than one attack. These 111 cases constitute the proved cases discharged from the Philadelphia General Hospital with the combined diagnoses between June 1936 and June 1944. Of this series the course was atypical in 60 per cent, nearly three fourths of the active cases and more than half of the inactive ones. The outcome of pneumonia is altered by the presence of tuberculosis. The death rate in this series was 38 per cent, with deaths twice as numerous when the tuberculosis was active (56 per cent) as when it was inactive (30 per cent). Reactivation of a tuberculous focus that is quiescent or an increase of disease in already active tuberculosis may be expected in 15 per cent of the patients who develop superimposed pneumonia, whether or not it is in the same lobe and whether or not it is specifically treated. Definite therapeutic implications have not been derived from this study. If bacterial antagonism is the correct explanation for the infrequency of pneumonia complicating tuberculosis, therapeutic use of the products of the pneumococcus might be made in the treatment of pulmonary tuberculosis.

Night Cramps in Young Men.—In the course of nine months at an Army Air Force installation 35 men presented themselves for treatment. Nicholson and Falk present observations on 23 of these cases. The average age of the men was 25 years. A person with night cramps is usually free from symptoms during the day, whether resting or walking. He retires without symptoms but is awakened by a cramping pain usually in the calf muscles, although any muscle group in the lower extremity may be involved. Rarely muscle groups in other parts of the body are affected. Vigorous rubbing of the leg or hopping about gradually relaxes the muscles, but there is often a residual soreness lasting for hours. In the treatment of night cramps the authors used quinine sulfate. More than a fourth of their patients failed to obtain relief. The majority of those who obtained relief required a number of doses. The effect of this drug is short lived and not cumulative. The authors are unable to explain why patients should have relief for many days and not infrequently for weeks after ceasing medication. In slightly more than a third of the cases, underlying changes could not be found. The most frequent disorder predisposing to night cramps was static foot deformity, which occurred in 12 cases. Five of these patients also had symptoms directly referable to the feet. In all these cases orthopedic appliances had been used, with partial relief of foot symptoms but without change in the occurrence of the night cramps. In none of the patients was there found any peripheral arterial disease, although in 2 cases there was old deep thrombophlebitis of the lower extremities.

Calcium Penicillin in Beeswax and *Peanut Oil.*—Romansky and Rittman found that a single injection of 300,000 Oxford units of calcium penicillin in 4.8 per cent beeswax (by weight) in peanut oil contained in 1 cc. produces and maintains effective levels of penicillin in the blood for about twenty-four hours and continues to be excreted in the urine for approximately three days. Calcium penicillin in beeswax and peanut oil maintains its potency for at least nine months at refrigerator, room and 37 C. temperatures. Deterioration did not occur after twenty-four hours at 56 C. or after two hours at 100 C.

Single Injection of Penicillin-Beeswax-Peanut Oil Mixtures in Gonococcic Urethritis.—Leifer and his associates gave 217 men with gonococcic urethritis single intramuscular injections of from 100,000 to 300,000 units of penicillin suspended in mixtures of beeswax and peanut oil. Local or systemic toxic manifestations were not noted. Of 88 patients treated with single injections of 100,000 units 74 were cured, and of 91 treated with 300,000 units 83 were cured. The results with 300,000 units of penicillin in beeswax-peanut oil were comparable to those obtained with 100,000 units of penicillin in saline solution given in divided doses; to produce equal results the mixtures required larger amounts of penicillin than did the saline solution. All patients were followed for twenty-one days, both clinically and bacteriologically. Of 24 failures

9 occurred after the seventh day, and 7 of these were detected by bacteriologic methods alone. These results stress the necessity for a minimal post-treatment observation period of twenty-one days. Sodium and calcium penicillin produced equally satisfactory mixtures Varying the concentration of beeswax from 4 to 12 per cent did not produce a significant difference in the results A single intramuscular injection of 1 cc. of a mixture containing 300,000 units of penicillin in 4 to 6 per cent beeswax by volume in peanut oil appears to be a highly satisfactory method of treating acute gonococcic urethritis.

Blood Pressure in Coronary Occlusion.—Reports cited by Donald indicate that hypertension is present in from 25 to 75 per cent of patients who have attacks of coronary occlusion. He does not accept hypertension as an etiologic factor, pointing out that there is a discrepancy between the incidence of occlusion and hypertension in the two sexes which is unexplainable. The ratio of coronary occlusion in females and males is about 1 to 4. The ratio of hypertension in females and males is about 3 to 2. The blood pressure probably gives the best indication of the immediate prognosis, low systolic readings and small pulse pressures being most ominous. In the first attack a previous hypertension offers a better immediate prognosis, as the blood pressure is less apt to fall to shock levels. The ultimate prognosis is much worse in persons having hypertension, as the damaged myocardium is incapable of keeping up the output of the heart, and the minute volume is decreased. With the development of a second occlusion the already hypertrophied and greatly damaged myocardium is more prone to develop massive pulmonary edema.

Effect of Water Containing Fluorine on Incidence of Dental Caries.—Klein states that in the course of a systematic dental examination of persons of Japanese ancestry residing in War Relocation Authority centers two groups of children at two different centers were examined in the summer of 1943 and again in the summer of 1945. The children relocated in the California center consumed fluoride free water originating from melted snows coming off a precipitous mountain. Analysis of this water revealed a fluorine content of 0.1 part per million, a value within the error of measurement. The children relocated to the Arizona center consumed water originating from two deep wells. This water contained fluorine to the extent of 3 parts per million During the two year interval 196 children were exposed to fluorine water in the Arizona Relocation Center and 120 consumed fluoride free water in the California center. Analysis of the dental findings obtained in 1943 and in 1945 reveals that a fluorine content of 3 parts per million in the drinking water is associated with a considerable reduction in new caries in teeth present in the mouth and free of caries at the beginning of exposure. These observations are not intended to constitute an endorsement for addition of as much as 3 parts per million of fluorine to community water supplies for the purpose of reducing the incidence of caries. The data provide information that the addition of small amounts of fluorine to community water supplies deficient in this element effects a reduction in the incidence of caries in the erupted permanent teeth of residents of school age and that such caries inhibition is most noticeable in the erupted teeth of the younger children.

Penicillin Therapy in Abdominal Surgery.—Wollgast observed 5 patients who were critically ill with generalized peritonitis. Treatment with penicillin was started late, and all of these patients died. Later 12 additional patients with peritonitis were treated more adequately. Seven received local treatment and parenteral therapy; 5 received only parenteral therapy. Local administration of penicillin in 3 instances consisted in instilling 50,000 units and in 4 other cases 100,000 units of penicillin into the abdominal cavity just prior to closure. Parenteral therapy was administered intramuscularly at three hour intervals. Dosage was varied from 10,000 units to 20,000 units every three hours, totaling 80,000 to 160,000 units every twenty-four hours. These patients also received all other accepted therapeutic measures. The postoperative course in 10 of these cases was unexpectedly mild. Twenty-five patients with infected wounds received penicillin both preoperatively and postoperatively as a prophylactic measure. Treatment consisted in parenteral administration of 10,000 of 15,000 units every three hours intramuscularly for an average of three or four days preoperatively. Treatment was continued postoperatively until the patient had been afebrile for at least three or four days. The average duration of treatment was eleven days. The postoperative course of these patients was very gratifying. Definitive operative procedures on contaminated wounds may be carried out earlier and with greater safety when penicillin is administered prophylactically. A man aged 31 was operated on in another hospital for perforated gangrenous appendix. On the ninth day a small incisional abscess was drained. On the eighteenth day his temperature rose to 103 F., with the onset of a septic course with daily elevations between 104 and 105 F. Improvement had not been noted over a seven week period prior to the use of penicillin, but definite improvement followed soon after initiation of this therapy. This serious postoperative complication was cured by penicillin therapy. Seven patients whose wounds became acutely infected following surgery were treated with penicillin. Six of these wounds responded remarkably to treatment.

Resection of Lung in Pulmonary Suppurative Diseases.—Carlton and Adams report observations on 59 patients with suppurative disease of the lung in whom the involved part was resected. Thirty-six of the patients had primary bronchiectasis, 9 had bronchiectasis secondary to bronchial tumors and tuberculosis, 7 had cystic disease of the lung and 7 had chronic nonspecific pulmonary suppuration. Patients with chronic infection of the lung should be hospitalized for three or four days for observation and laboratory examinations before operation. They should receive routine laboratory study. If anemia and hypoproteinemia are present they are corrected by transfusions of whole blood. Stereoscopic roentgenograms of the chest are made. Bronchography, usually by the aspiratory method, is carried out under fluoroscopic control, and all lobes are filled and spot films are made. For operation adequate exposure is essential. The phrenic nerve is then crushed. This decreases the motion of the diaphragm, facilitates the technical procedures and aids in the rapid obliteration of the remaining space following resection. The authors used the tourniquet technic and closure of the bronchial stump with mattress sutures. During the past two years they have used the dissection technic with individual ligation of vessels as worked out and described by Blades and Kent. The four most important factors in the postoperative care are (1) avoidance of anoxia, (2) maintenance of a clear bronchial tree, (3) early expansion of the remaining lung on the operative side and (4) control of infection. Chemotherapy has been a major factor in the prevention of serious postoperative infection. There were 2 deaths in 45 operations made on 36 patients with bronchiectasis, 20 of which were bilateral.

Congenital Malformations of First Thoracic Rib and Cervical Rib Syndrome.—White and his associates report 10 new instances of congenital abnormality of the first thoracic rib. Five of these have come to operation for the relief of specific complaints, while 5 others have remained wholly asymptomatic. First rib malformations generally consist of a rudimentary structure terminating in a synostosis or pseudoarthrosis with the second rib near the scalene tubercle or in a free end in the soft tissues at the base of the neck, which may be connected by a ligamentous band with the manubrium sterni. On rare occasions the first rib may have a joint near its lateral angle before it fuses with the second. Other skeletal abnormalities which are frequently present and cause distortion of the thoracic outlet consist in deformities of the second rib, the upper end of the sternum, scoliosis of the cervicothoracic spine and vertebral anomalies. Symptoms and clinical evidence of abnormal first ribs consist in supraclavicular bony prominence, irritation or paralysis of the brachial plexus and compression of the subclavian vessels as they cross the defective rib. Cervical arthritis, early carcinoma of the thoracic apex and herniation of the lower cervical intervertebral disk must be considered in the differential diagnosis of brachial neuralgia, even in the presence of an anomalous rib. Malformations of the first thoracic rib cannot be differentiated clinically from cervical ribs. They can be accurately diagnosed in an anteroposterior x-ray film which includes all the cervical and uppermost thoracic vertebrae, provided the film is taken with a long exposure and the mandible in motion. A considerable proportion of first rib deformities are large enough to cause mechanical compression of the nerves and vessels at the thoracic outlet. When symptoms are attributable to this condition, conservative orthopedic measures should be tried before surgical intervention. Scalenotomy alone rarely suffices to decompress these structures but must usually be accompanied by radical resection of the rib from a point close to its articulation with the transverse process forward to its attachment to the second rib or where it disappears beneath the clavicle.

Hodgkin's Disease: Study of 30 Cases. P. David.—p. 1542.

Pericoronary Neurectomy in Coronary Disease.—Fauteux and Swenson report two series of experiments on dogs. Sutton and Lueth's method of occlusion of the coronary artery was used in the first series of 10 dogs. In 9 of the animals a positive sensory response was obtained when the coronary artery was temporarily occluded. Pericoronary neurectomy was performed on 10 dogs in the second series of experiments. These dogs were in excellent health at the end of one month. After this interval the ramus descendens of the left coronary artery was ligated. A definite negative sensory response was obtained in 6 of the animals; there was a doubtful affective response in 3, and in only 1 of the 10 animals was a positive sensory response obtained. Pericoronary neurectomy abolishes pain of coronary origin. In addition it has the advantage that destruction of nerve structures vital to other organs can be avoided. The operation does not interfere with cardiac function. Pericoronary neurectomy associated with ligation of the large coronary vein was performed on 1 patient in September 1944 and on another patient in June 1945. Both had attacks of angina pectoris and were unable to work. After the operation the first patient was able to resume his work. This suggests not only that the pain reflexes have been blocked but also that cardiac activity has been improved. The second patient has not yet resumed his work, but he goes up and down the stairs in his house and walks long distances without experiencing discomfort.

Globulin of Human Umbilical Cord Blood in Prevention and Attenuation of Measles.—Foisy and Larivière report an epidemic outbreak of measles which started in an asylum of infants in Montreal on June 24, 1944. Fifty-one of the 300 inmates of the asylum between the ages of 2 and 6 years had measles in 1939 and had acquired active immunity. Sixty-three infants of 249 without active immunity had measles on July 10, 1944, when immunization of the remaining 186 infants was started. Five cc. of globulin of human umbilical cord blood was given to each of these 186 infants. A single anaphylactic reaction occurred, with a general reaction and a temperature of 105 F. for eighteen hours. Measles developed in 42 infants exposed more than five days prior to the immunization. One hundred and forty-four had been exposed less than five days prior to the immunization. Forty-four of them did not develop measles; of the 100 who did, only 3 presented the usual type of the disease, while in 97 the disease was attenuated. In the 44 who did not develop measles, the average acquired passive immunity was of more than a month's duration, since the last case of measles occurred in the asylum on Aug. 3, 1944.

Effect of Urine on Endameba Histolytica.—Watson and his associates report experiments which demonstrate that at the temperature of the human body urine is lethal to Endameba histolytica. This ameba is unable to live and multiply in urine unless it is diluted to nearly one tenth of its normal concentration. The effect of urine is produced slowly, beginning to be perceptible only after about two hours' exposure. After twenty-four hours the great majority of the amebas have become degenerate and unrecognizable. The toxicity of urine is partly explained by the effects of acidity, of osmotic pressure and of urea and ammonia in the urine. It seems highly improbable that E. histolytica can establish itself in any part of the urinary tract where it will be continually immersed in urine, even as dilute as that in the kidney tubules. Hence amebas which gain entrance to the kidney, the ureter, the bladder or the urethra (by direct introduction of the organisms into the urethral aperture, by fistulous extension of a rectal ulcer or by bursting of a liver abscess) will probably succumb to the lethal effect of the urine. Since, however, the amebas retain their motility for upward of two hours, it is possible for some to penetrate the tissue forming the walls of these organs, where, protected from the urine, they can multiply and produce lesions. Any condition of the host in which the composition of the urine is abnormal, showing low osmotic pressure or low ammonia and urea content, or in which preexisting disease has destroyed part of the protective epithelium lining of the urinary tract, would facilitate the penetration and establishment of E. histolytica in the tissues. Probably, once amebic lesions had been established, amebas would periodically emerge into the cavity of the urinary tract and be swept out in the urine during micturition and be found in the urine.

Prolonged Administration of Quinacrine.—The experimental subjects were 43 healthy men, Oxford undergraduates and soldier volunteers who had not taken quinacrine previously. Approximately 0.1 Gm. of quinacrine daily was given over a period of nine to twelve months. Tests of liver and kidney function were made and compared with tests done before the administration of quinacrine. Evidence indicated that this course of quinacrine did not impair the efficiency of the liver or the kidney.

Hematologic Effect of Prolonged Use of Quinacrine.—Sixty-five women and 30 men were given quinacrine in a dosage of 0.4 to 0.7 Gm. weekly for four to ten months. During this period there was not a significant change in the red cell count, the white cell count, the hematocrit or the erythrocyte sedimentation rate. A small rise in hemoglobin concentration occurred in the men in both experimental and control groups.

Gaucher's Disease: Radiologic Diagnosis.—Tennent presents the history of a girl, aged 11, who had an enlarged liver and spleen. X-ray examination revealed slight expansion of the lower femoral diaphyses, with cortical thinning and generalized osteoporosis. Following splenectomy, the patient made an uninterrupted recovery. Sections of the spleen showed the splenic sinusoids distended with the so-called Gaucher's cells. The whole skeleton was examined but, as anticipated, significant changes were not found in any bones except the femurs. The disease was of the visceral type, with slight anemia and few bone changes. The lower ends of both femurs showed about the earliest stage at which roentgenologic diagnosis of Gaucher's disease can be made. Without information of splenomegaly the film might have been passed over, but, if comparison is made with a normal child of the same age, certain diagnostic points may be elicited. First there is general osteoporosis, which increases in degree from above downward. Secondly there is expansion of the lower ends of the bones, mainly manifested on the medial aspects of the femurs, and, while there is a true overall increase in the breadth, the lateral wall takes little part in this increase during the earliest stage of the disease. Thirdly there is cortical thinning and small medullary areas of erosion of the trabeculae. The cortical thinning starts in the midshaft and again is largely confined to the medial wall. In early cases the chief danger is that it may be mistaken for an osteomyelitis and the bone needlessly drained.

Prognosis of Chronic Miliary Tuberculosis in Children. R. B. Illing. —p. 79.
Syphilis of Lung in Bantus. B. A. Dormer, J. Friedlander and F. J. Wiles.—p. 85.
*Etiology of Silicosis. L. W. Hale.—p. 91.

Etiology of Silicosis.—Conditions such as chronic sinusitis with postnasal drip, or repeated catarrhal bronchial infections, which temporarily or permanently destroy cilia, predispose to silicosis. Dust which has entered the bronchioles and the alveoli is not in contact with ciliated epithelium and depends on the pulmonary phagocytes and the lymph vessels for its removal. Any disease process (e. g. pneumonia) which affects the alveolar wall, the lymph vessels or the lymphoid aggregations will, by producing scarring in these delicate structures, impair their function of carrying foreign matter to the lymph nodes and will thus predispose to silicosis. In the phagocyte containing ingested silica changes closely resembling those seen in a tubercle appear. The cell enlarges, the cytoplasm increases, lipoid droplets are distinguishable in the cytoplasm and later the nucleus may divide repeatedly, resulting in the formation of a typical Langhans giant cell. Some of the phagocytes, in passing through these stages, appear to become "mummified" and their nuclear structure ceases to take stains, but the cell envelop may not disintegrate for a long time and the silica particles remain within it. The essential feature of the silicotic process is an excessive fibrosis in the intrapulmonary lymphoid aggregations, together with a fibrosis of the perilymphatic connective tissue and a hyaline modification of the fibrous tissue due to the specific effect of silica. The nodules so formed impede the flow of lymph. The nodules are tough, even hard, and contain gritty feeling foci. There is a zone of black surrounding them owing to the presence of carbon particles trapped among the fibrous tissue. Both the rate and the extent of fibrosis are in inverse proportion to the size of the silica particle, those between 0.5 and 1 micron being most reactive; particles above 10 microns cause a standard degree of fibrosis without tendency to progression. Particles smaller than 0.002 micron were not retained in the tissues, caused little reaction and were excreted in the urine. While pulmonary tuberculosis is among those respiratory conditions which predispose to silicosis, silicosis renders a man more vulnerable to tuberculosis. Even with modern hygienic conditions, 75 per cent of silicotic patients die of pulmonary tuberculosis.

Neurologic Complications of Infective Hepatitis.—Stokes and his associates classify less well recognized neurologic findings in infective hepatitis and separate them into four main groups. First, the picture commonly found in the fatal case. Second, a symptom complex comprising generalized or localized muscular rigidity with increased tendon jerks, sometimes but not invariably associated with extensor plantar responses; in addition choreiform movements have been observed, and in 1 case a parkinsonian tremor. Third, a group of cases with large focal hemorrhages into nervous tissue, which may or may not produce localizing signs. Fourth, those cases showing signs of peripheral neuritis in which there is good evidence for direct relation to the onset of infective hepatitis.

*Actinomycosis Successfully Treated with Penicillin: Report of 2 Cases A. J. C. Hamilton and H. J. R. Kirkpatrick.—p. 728.

Actinomycosis Successfully Treated with Penicillin.—Hamilton and Kirkpatrick present 2 cases of cervicofacial actinomycosis. The first concerned a linotype operator aged 35 and the second a railway porter aged 15. In both cases penicillin was administered systemically by intramuscular injection. During the first half of the course of treatment the dose was 33,000 units every three hours; thereafter the dose was reduced to 25,000 units every three hours. There was a gradual diminution in the size of the lesion. Treatment was continued until the discharge had ceased and the lesions had greatly diminished in size. The first patient received in all 5,800,000 units of penicillin and the second patient 5,200,000 units. A month after discharge from the hospital there was slight thickening of the tissues at the site of the lesion, but evidence of an active inflammatory process was not present. The results obtained demonstrated the curative effect of penicillin, but more prolonged observation of the patients will be required to establish that viable Actinomyces capable of proliferation does not remain embedded in the tissues. According to examinations carried out by Garrod, different strains of Actinomyces differ in their susceptibility to penicillin. Whereas two strains showed approximately the same degree of sensitivity as the standard staphylococcus, a third strain was eight times as resistant, a fourth strain was four times as resistant and a fifth strain grew sparsely and atypically in sixteen times the concentration of penicillin tolerated by the staphylococcus.

Erythroblastosis Fetalis and Antepartum Hemorrhage.—Burch and Allot investigated all cases of antepartum hemorrhage occurring at St. Alfege's Hospital between February and June 1945. It was found that 5 of 10 of the mothers who had antepartum hemorrhage were Rh negative with Rh positive husbands and 3 of these had anti-Rh agglutinins. Of the 3 who were delivered soon after the antepartum hemorrhage, 1 had a child with only a moderate degree of jaundice who recovered without transfusion, another a child with gross hydrops and the third a child stillborn, possibly as a result of the course of labor. In the 2 mothers who were not delivered until some weeks after the first hemorrhage the fetus was stillborn, macerated and of a size corresponding roughly with death at the time of onset of the bleeding. The author concludes that a woman in whom isoimmunization can occur is prone to accidental antepartum hemorrhage, and the ensuing placental damage may be a factor in transmission of antigen and agglutinin.

Effect of Postoperative Exercises and Massage on Pulmonary Embolism.—At the beginning of 1937 a massage department was established at the Chelsea Hospital for Women. The members of the massage team were to instruct and supervise postoperative exercises and to carry out massage in all cases after abdominal operations and operations for the repair of genital prolapse. The incidence of fatal embolism decreased by more than 50 per cent during the seven year period subsequent to the introduction of the massage and exercise procedure.

Transmission of Infective Hepatitis.—Findlay and Willcox describe their studies on transmission of infective hepatitis by administration of feces and urine from spontaneous and experimental cases. Of 99 recipients of possibly infected material, feces or urine, 24 are regarded as having given a positive response: 12 with definite icterus and the symptoms of infective hepatitis, 12 with subicterus but with biochemical changes in urine and blood and slight symptoms. Of the primary inoculations which were positive 12 had definite icterus and 4 were subicteric; of the 8 positive second passages all were subicteric. If the persons receiving neoarsphenamine are discarded there are 18 positives, but it is not considered that the injections of neoarsphenamine were alone responsible for these 6 positives. The explanation for this comparatively low proportion of positives might be destruction of the causal agent by the gastric juice or preexisting immunity. The immunity induced by one attack of infective hepatitis is probably considerable in view of the small number of true second attacks. Since subicteric cases undoubtedly occur during outbreaks of infective hepatitis, the chances of exposure to virus and thus the possibility of acquiring immunity must be considerable among the general population. It would seem probable that the virus of infective hepatitis has two possible ports of entry: through the nasopharynx as a droplet infection and through the alimentary canal as the result of contamination of food by infected feces or urine.

Intracisternal Penicillin in Staphylococcic Leptomeningitis.—The case of staphylococcic leptomeningitis described by Worth developed in a man with osteomyelitis of the spine following diagnostic lumbar puncture. The situation was desperate, and radical laminectomy, with removal of all dead bone, was required together with intracisternal penicillin, the only route available owing to the lumbar sepsis. Cisternal puncture produced turbid cerebrospinal fluid, and many staphylococci were seen in a direct film. Fifty thousand units of penicillin was given intracisternally and 30,000 units intramuscularly every three hours. Intramuscular penicillin and daily cisternal punctures with intracisternal instillation of penicillin were continued for a week. Interruption of the treatment for a single day produced an immediate unfavorable change in the clinical picture. Further intracisternal penicillin in doses of 50,000 and 30,000 units rapidly controlled the condition. The intracisternal injection of these large doses did not produce severe reactions.

Effect of Large Doses of Alkali on Kidney Function.—A Malaria Research Unit studied in normal subjects the effects of intensive alkali treatment. These investigations assert that intensive alkali therapy of this kind is accompanied by dangers, and its efficacy is open to question. Three men were given 60 grains (4 Gm.) of sodium bicarbonate and 60 grains of sodium citrate every two hours. One subject received this course for one day, 2 subjects for three days. All the subjects on alkali had disturbances of renal function. In 1, on the alkali course for three days, this was severe and led to a threefold increase in blood urea. All the subjects on alkali developed fairly intense alkalosis, not entirely compensated, together with sodium and water retention. There was dilution of the blood by about 10 per cent. Both persons on alkali for three days complained of symptoms. A fourth subject was given an equivalent amount of sodium chloride for twenty-four hours. He showed a slight degree of sodium and water retention without alteration of renal function. Large doses of alkali should not be administered in conditions in which renal failure may supervene.

Acute Brachial Radiculitis.—Dixon and Dick's report is based on a detailed study of 16 typical cases of brachial radiculitis. It invariably starts with some pain in the root of the neck and shoulder region. Usually the pain is very severe, and often it complicates the course of an acute infectious fever or the convalescence from a surgical operation. Palsy is often not noticed for several days, in fact not until the pain begins to abate; then the patient usually finds he is unable to lift his arm. Muscular wasting follows and is usually extensive at the end of fourteen days. An area of sensory loss, although not complained of by the patient, is usually found over the deltoid muscle. The authors have excluded cases in which wasting and weakness was not well defined in the muscles of the shoulder girdle and trauma or injection of foreign serum appeared to be the precipitating cause. The authors followed the course of 16 patients over a considerable period. Neither fitting with abduction splints nor treatment with vitamin B_1 appeared to alter the course of the disease. Ten patients have shown complete functional recovery after eight to eighteen months. One was so far recovered at the end of five months that he returned to duty, a second with complete recovery on one side is recovering from a relapse on the other side and a third is still showing slow recovery at the end of two years. Of 3 cases that have been stationary or are deteriorating, 1 shows very little disability, the diagnosis in a second is doubtful, and only the third presents a severe residual disability. Recurrences developed in 5 cases, 2 at the end of six weeks, 2 at six months and 1 at the end of five years.

Extensive Interstitial Calcinosis.—Medvei reports a case in which extensive interstitial calcinosis was associated with diffuse osteoporosis, dermatomyositis and scleroderma in a woman aged 32. The calcification made the patient look as if she was covered with armor plating. Fundamental derangement in the calcium and phosphorus metabolism could not be shown chemically. Focal oral infection was present. Reduction of the parathyroid tissue by operation did not improve the patient's condition. The microscopic appearance of a piece of excised muscle, the eosinophilia, the excessive erythrocyte sedimentation rate and the oral infection all point to an inflammatory process in the muscles and, with the edema and the skin lesion, complete the picture of a case belonging to the dermatomyositis-scleroderma group of Dowling and Griffiths.

Middle Meningeal Hemorrhage.—Orgias describes 7 cases of middle meningeal hemorrhage which were encountered among 1,529 cases of head injury. Of the 67 deaths from head injury, 3 were due to middle meningeal hemorrhage. A detailed inquiry into the circumstances of the accident and the condition of the patient are of great importance for a correct diagnosis. The most useful sign has been coma or a deepening coma or a drift into unconsciousness. The pupil has been dilated or has become dilated on the affected side in all these cases. The reaction to light was variable, usually depressed or absent. The pulse rate was between 50 and 60 and full. The blood pressure was moderately elevated. There was usually some increase in tone of the limbs or loss of movement on the contralateral side. An inspection of the head with palpation is important, as this may reveal bruising or edema on the side of the lesion There is usually a fracture across the line of the middle meningeal artery. In certain instances without a history the diagnosis can only be suspected and an exploratory trephine is necessary. Operation should not be delayed. None of the patients showed a dramatic return of consciousness. Therefore efforts had to be directed toward preventing pulmonary complications and maintaining nutrition. The foot of the bed was raised and the patient nursed on the side and rolled to the opposite side hourly. A special nurse kept the airway clear with suction Three pints of nutrient fluid of 1,500 calories was given by stomach tube daily. The hemoglobin was returned to normal as soon as possible by blood transfusion to ensure adequate oxygenation of the brain. Sulfadiazine 4 Gm. daily given by stomach tube helped to control pulmonary infection. All patients were given ½ grain (32 mg.) of phenobarbital twice daily for several months in the hope that traumatic epilepsy could be avoided

Oxygen Content of Blood and Hematocrit Determination.—Berk shows that differences in the oxygen content of samples of venous blood may alter the hematocrit by as much as 3 per cent. This disturbance affects the mean corpuscular hemoglobin concentration figure by up to 3 per cent and the mean corpuscular volume figure up to 18 cubic microns It is suggested therefore that all samples of blood should be standardized by bringing them into gaseous equilibrium with the atmosphere before the performance of a hematocrit determination

Susceptibility of Phthirus Pubis to Infection with Typhus.—Chung fed three batches of laboratory bred pubic lice on 3 typhus fever patients for from seven to nine days during the height of the disease. These pubic lice were found to be infectious, as demonstrated by guinea pig inoculations. The inoculated guinea pigs showed typical febrile reactions and not infrequently also scrotal swelling. Rickettsia prowazeki was demonstrable in scrapings as well as in tissue cultures of the inflamed tunica and in the intestine of body lice inoculated rectally with the brain emulsion of infected guinea pigs. The positive feeding experiments reported here suggest that under certain circumstances the pubic louse may act as a transmitter of typhus

*Treatment of Hemophilia with Dioxydiethylstilbestrol (Stilbestrol). P Chassagne —p 282.

Edematous Gastritis.—Edematous gastritis may be associated with severe anemia, cachexia, certain neoplasms and ulcers, but it may also occur as an autonomous disease. It often alternates with urticaria and seems to be an internal manifestation of urticaria Clinically the edematous gastritis may be absolutely latent It is manifested by indigestion and discomfort, by pain and by heartburn. Gastroscopy assists in the diagnosis. There may be present an edematous swelling of the mucosa with a pale central zone and a darker periphery; the edema may be present on the lesser curvature, the anterior pillar, the fornix or the pillars of the antral sphincter, but the pylorus is not frequently involved There may be small erosions on an edematous base, some mucus and a few eosinophils The duration of the edematous gastritis may be from two to eight days In the great majority of the cases the condition is caused by the ingestion of certain foods, particularly of mollusks, crustacea, fish and sausage. Histamine frequently is the immediate cause. A specific predisposition is to be considered. With certain patients it consists in a preliminary atrophy of the mucosa, in vagotonic persons it consists of hypomyxia and hypoleukocytosis and in still others the predisposition consists in hyperergy close to anaphylaxis. Treatment consists of a strict diet and administration of bismuth and charcoal Atropine may favor leukopedesis and myxorrhea and may act as an antianaphylactin. Desensitization may be effected by the administration of peptone and pepsin prior to meals.

Diethylstilbestrol Treatment of Hemophilia.—Intramuscular injections of 0 5 to 1 0 mg. of diethylstilbestrol in oil every day for five days were effective in restoring the coagulation time to approximately normal levels The same effect may be produced by the oral administration of a 5 mg. tablet three times a week. Chassagne suggests large doses of the drug during hemorrhagic periods. Five to 10 mg. should be administered by mouth every day for one week, or 1 to 5 mg. should be given intramuscularly every day during this period. Several days are required to obtain an improvement in the coagulation time. Apart from the hemorrhagic periods, a prolonged treatment is required. This should consist of oral administration of 1 to 3 mg. of the drug every day or every second day for several weeks. Pigmentation of the genitals following administration of the drug was observed in adults and in adolescents.

Icterus Due to Arsphenamine Compounds.—Marshall reports clinical observations of postarsphenamine jaundice in syphilitic patients in England during the period 1941 to 1944. From 1941 to 1943 treatment of syphilis consisted of four series of injections with neoarsphenamine and preparations of bismuth; each series consisted of ten injections of 0.6 Gm. of neoarsphenamine and ten injections of 0.20 Gm. of a bismuth compound at the rate of one of each weekly. There was a rest interval of one month after each of the series. Fifty per cent of the syphilitic patients to whom this treatment was given developed jaundice, the majority on about the hundredth day after the first injection. In 1944 a rapid twenty day treatment with oxophenarsine hydrochloride and bismuth or penicillin was instituted. Jaundice likewise occurred on the hundredth day after this treatment. Postarsphenamine jaundice is clinically indistinguishable from infective hepatitis, significant biochemical difference between the two has not been demonstrated, and pathologically it has been shown by liver biopsy that changes in the liver are similar in the two conditions. Postarsphenamine jaundice is probably spread by infected syringes. By boiling the syringes before and after injections the percentage of icterus was reduced from 50 to 10. Each of 10 patients was given a special new syringe for individual use boiled before and after injection. There was not a single instance of jaundice among these patients up to the hundred and fiftieth day of the treatment, but 1 of the 10 developed jaundice on the eighty-third day after he had received one injection at another hospital. Methionine and cystine were given by mouth to some of the patients on neoarsphenamine treatment. These amino acids were administered for a period of three to six weeks, beginning one week prior to the hundredth day of the arsenic treatment. While 50 per cent of the control patients developed jaundice on the hundredth day of the neoarsphenamine treatment, the percentage of jaundice among those treated with methionine was considerably reduced and in those in whom it occurred it did so not on the hundredth day but much later. The mode of action of the methionine is not known.

Focal Infection Due to Salivary Stone with Chronic Inflammation of Submaxillary Salivary Gland. A. Weder.—p. 134.
Central Paralysis of Superior Laryngeal Nerve. R. Luchsinger.—p. 139.

Bronchial Adenoma.—Nager reports 7 cases of bronchial adenoma. Three patients presented primary symptoms of the disease at the beginning of the third decade of their life, 2 patients did so in the course of the third decade and only 2 patients were over 40 years of age. There were 4 female and 3 male patients. Disturbances of respiration and pulmonary symptoms depend on a considerable increase in the size of the tumor and suggest that the beginning of the tumor may be traced to the end of puberty, since as a rule bronchial adenoma grows slowly. In the patients in the third decade of life the course of the disease seemed to be more rapid. Spontaneous hemoptysis occurs when the vascular tumor has infiltrated the mucosa and reached the thin epithelial layer. The first stage of bronchial adenoma, which is characterized by asthmatoid wheezing and by hemoptysis, was presented by 2 of the author's patients. The second stage, which is characterized by the symptoms of bronchial stenosis and its sequels such as atelectasis, was presented by 2 patients, and the third and fatal stage, characterized by suppurative disintegration of tissues such as empyema or gangrene of the lung, was present in 2. A favorable prognosis of the benign bronchial adenoma depends primarily on early diagnosis. The prognosis is unfavorable in late cases. Bronchoscopy is essential for early diagnosis. In the last three years it has been performed in 300 cases at Nager's clinic in Zurich without any untoward reaction. Improved or normal conditions in the lumen of the bronchi resulted in the early cases from excision of the tumor followed by electrocoagulation. Lobectomy or pneumectomy are contraindicated by the proximity to the hilus. Surgical methods of treatment are indicated for tumors within the deeper layers. Hemorrhage associated with sudden cessation of respiration and death resulted in 2 cases from electrocoagulation. It is suggested that a sudden reflex—irritation of the vagus—may produce a shocklike cessation of respiration or it may result from a tetanic bronchial spasm and may at the same time produce an ectasia of the lung capillaries associated with effusion of blood into the interstitial tissues and into the alveoli.

Leiomyoma of Prostate.—Rohrbach investigated the occurrence of fibromuscular proliferation in the prostate of 100 men, the majority of whom were over 40. Most of the specimens were necropsy material. Leiomyomas of the prostate are nearly as frequent as adenomyomatous nodules. They are found underneath the urethral mucosa from the colliculus seminalis to the urethral orifice and consist partly of spirally arranged muscle fibers and connective tissue septums with profuse vascularization. They seem to develop at about the same time as the glandular nodules. However, the myomas seem to remain small up to the age of 65 and only then do they begin to grow considerably. This contradicts the assumption of the elicitation of glandular hypertrophy of the prostate by estrogen but speaks for the promotion of the growth of leiomyomas by this substance at the higher ages.

Pathologic Anatomy of Bronchial Adenoma.—Von Albertini presents microscopic studies on 10 cases of bronchial adenomas, of which 3 were discovered at necropsy; 7 of the patients were under clinical treatment. Four of these 7 died, but in only 2 was necropsy performed. Necropsy material from 5 cases and biopsy material from 5 cases was obtained for pathologic studies. The microscopic character of the tumor justifies the term solid adenoma. There is no justification for terms like carcinoid and basal cell carcinoma. He assumes a close relationship between bronchial adenoma and bronchial carcinoma because, histogenically, both seem to be derived from bronchial epithelium. The adenoma may possibly represent a hamartoma from supernumerary bronchial buds.

*Tuberculous Meningitis in Infant Vaccinated with BCG Vaccine: Case. R. Gorlero Bacigalupi.—p. 545.

Tuberculous Meningitis.—Gorlero Bacigalupi reports that an infant who had received BCG vaccine within the first three days after birth, and whose parents and family were normal, developed normally up to 22 months of age, when he developed acute tuberculous meningitis and died three days later. The diagnosis was confirmed by cultures of the cerebrospinal fluid and by inoculation of the cerebrospinal fluid into guinea pigs. There was a history of contact of the infant with a tuberculous neighbor when he was 8 months old.

Book Notices

Man Against Pain: The Epic of Anesthesia. By Howard Riley Raper. Cloth. Price, $3.50. Pp. 337, with illustrations. New York; Prentice-Hall, Inc., 1945.

Here is the exciting story of man's conquest of pain, written in a popular style. From the early crude attempts at narcotizing the surgical patient by drugs or by a blow on the head the reader is introduced to methods and men who "came close" to the discovery but failed to visualize the great possibility before them. The chapters dealing with the discovery of anesthesia and the controversy arising as to the priority and credit transcend mere popular interest and constitute a thorough study of the subject. As a result of his own researches into the subject and of critical analysis of the literature the author offers the following conclusions: Sir Humphry Davy suggested the use of nitrous oxide as a therapeutic agent to produce anesthesia in 1800 but did not act on his own suggestion or stimulate any one else to act by it. Henry Hill Hickman had the idea of anesthesia clearly in his mind and tried to anesthetize animals in 1823 but never found the right agent for his purpose, never carried his experiments to the human subject and was unable to stimulate others to do so. Robert Collier in 1839 mixed mesmerism and the fumes of alcohol and got as far toward anesthesia as it is possible to get with such a mixture. Charles T. Jackson may have anesthetized himself with ether in February 1842 but failed to do anything further about it until 1846, when he suggested to Morton that it might be substituted for nitrous oxide gas. Crawford W. Long used ether in March 1842 for the removal of a tumor but was too unimaginative to realize the possibilities in etherization, let four and a half years slip by without even trying to introduce it into general surgical practice, and played no part whatever in the events which gave anesthesia to mankind. E. R. Smilie started on the right track in the spring of 1844 with his mixture of opium and ether but mistook the action of the ether for that of opium and abandoned the idea. Horace Wells in December 1844 set in motion the train of events which brought the gift of inhalation anesthesia to mankind. He conceived the idea, tested it repeatedly, announced it, explained it and demonstrated it to many, including Morton. W. T. G. Morton, acting on information from Wells and a suggestion from the chemist Jackson, substituted ether for nitrous oxide gas and gave a demonstration in 1846 that served to announce anesthesia to the world.

The author is not surprised that Long, Morton and Wells have all been called discoverers. Long is the discoverer if one considers only the matter of priority. Morton is the discoverer if one considers only the question of who introduced anesthesia, and Wells is the discoverer in the sense that he found, recognized, demonstrated and acclaimed it and started it on its way to being introduced by Morton. Thus the author accords the palm of the true discoverer of anesthesia to Horace Wells. The author's conclusions are based partly on such facts as could be ascertained, partly on a skilful evaluation of the characters of the men involved and on a critical analysis of the existing literature on the subject of controversy. The author is not to be considered a Horace Wells partisan but rather a conscientious student of the history of the discovery of anesthesia.

DDT for Institutions: A Report on the Methods of Preparations and Use of DDT for Insect Control. Research Department, Hospital Bureau of Standards and Supplies, Inc. Paper. Price, 50 cents. Pp. 12. New York, 1945.

A twelve page mimeographed pamphlet has been prepared on DDT by the Research Department of the Hospital Bureau of Standards and Supplies. This pamphlet is bound and perforated for filing. The report has been checked by the Department of Agriculture for accuracy. Discussion is brief and concise and is pointed toward the practical application of insecticides containing DDT in hospitals. The information in this report will also be of value to superintendents of other types of institutions, homes and office buildings. Nonmember hospitals can purchase copies of the pamphlet. Preparation, effectiveness, usable forms, precautions, government control, history, summary and selected bibliography are the important divisions of the subject matter.

Black Widow: America's Most Poisonous Spider. By Raymond W. Thorp and Weldon D. Woodson, B.S., M.A. With a foreword by Emil Bogen, M.D. Cloth. Price, $3. Pp. 222, with illustrations by the authors. Chapel Hill, N. C.: University of North Carolina Press, 1945.

Most spiders are inoffensive and indeed useful creatures which contribute to the control of flies and other disease carrying insects and offer artistic and moral exemplars by their clever and indefatigable weaving. The particular species which forms the subject for this book, however, stands convicted by the evidence here marshaled against her as a vicious biter whose potent poison has brought suffering to thousands and death to hundreds of our fellow Americans.

The book opens with a review of the popular folk lore and literary references to spiders, an account of the "tarantula" and other reputedly dangerous spiders, leading to the conclusion that "the most universally distributed 'dangerous' spiders are those of the genus Latrodectus, and it is they, more than all others, which are responsible for serious cases of spider bite."

The black widow spider has been observed in each of the forty-eight states, and similar species are found in all of the six continents. During the past two centuries more than twelve hundred bites from this arachnid have been described by lay and medical observers. The striking clinical phenomena which result are detailed and amplified by the results of experimental bites on animals and man. Diagnosis is usually not difficult if the condition is considered, and effective symptomatic and specific treatments are available.

The sensational publicity given the black widow and her role in suicide, murder and other medicolegal matters is illustrated by the experiences of the authors. The appearance of the spider, her multiplication and life cycle, her diet and sites of predilection for her ungainly webs, and the artificial and natural factors in her control are clearly presented.

Extensive appendixes contain previously unpublished lay and medical case reports, chronological and geographic tables of the occurrence of spider bites, a large and representative bibliography and a detailed index. Despite the popular style of presentation, this book contains a wealth of authoritative information on the subject which should be of interest to all who may come in contact with this nefarious character.

The Psychoanalytic Study of the Child: An Annual. Anna Freud, Heinz Hartmann, M.D., and Ernst Kris, Ph.D., managing editors. Volume 1. Cloth. Price, $6. Pp. 423, with 3 illustrations. New York: International Universities Press, 1945.

This edition represents the first volume of a contemplated annual production under the same title. It is an Anglo-American venture and the managing editors are Anna Freud, Heinz Hartmann and Ernst Kris. The contents consist of assembled papers of British and American writers relative to numerous aspects of child psychology. This book, as well as future editions, is primarily intended as a guide to specialists in the field of child study, but other students in allied fields will find it of great value in understanding behavior problems in all ages. As stated on the cover, "The future of our society will depend on the capacity of our children to withstand the ever mounting tensions in the world of today and tomorrow. To guide the formative years of this generation is the critical task facing those who have assumed this responsibility. Adequately to do this requires both a genuine understanding of the mental and psychic development of the child, as gained through psychoanalysis, and the knowledge of how to translate these insights into practice." In this volume child therapy and child guidance are represented by extremely interesting and comprehensive case presentations. Many of the contributors are well known for their progressive insight into emotional problems of children, and the subjects chosen for publication are well selected.

The book contains five chapters, on genetic problems, problems of child analysis and child development, guidance work, problems of education and surveys and comments. Unfortunately an index is not included, and many of the papers have bibliographies following the text which are not alphabetically arranged and are therefore somewhat confusing to the reader who wishes to investigate the references given. However, this book helps to fill a real need, and these are merely format criticisms which may be easily corrected in future editions.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

VITAMINS DURING PREGNANCY

To the Editor:—What are the recommended dosages (not the minimum daily requirements) for the vitamins and minerals during the third trimester of pregnancy? What are the greatest amounts of each vitamin and mineral that could be taken during this period without causing any danger to the mother or to the fetus? M.D., New York.

Answer.—The Food and Nutrition Board of the National Research Council has established Recommended Dietary Allowances for the principal nutritional essentials. These are given for various age groups, states of physical activity, pregnancy and lactation. During pregnancy the recommendations apply to the latter half. The quantities recommended are 6,000 units of vitamin A, 1.8 mg. of thiamine, 2.5 mg. of riboflavin, 18 mg. of niacin, 100 mg. of ascorbic acid, 400 to 800 units of vitamin D, 15 mg. of iron, 1.5 Gm. of calcium from food sources and the same for phosphorus (greater quantities if from pure chemical compounds) and 85 Gm. of protein. The recommended amounts of the lesser minerals are not stated quantitatively, but 0.2 to 0.3 mg. of iodine daily is important. This can be secured from the regular use of iodized salt. A good diet normally will supply sufficient copper. Vitamin K is often given to the mother toward the end of pregnancy in amounts of 1 to 2 mg. daily.

At the present time knowledge of danger from use of vitamins in excessive amounts under practical circumstances is limited to vitamin D. The dosage of this vitamin should not greatly exceed 400 to 800 units daily, since larger quantities reduce the efficiency in promoting calcium absorption and much higher levels may withdraw calcium from the bones. Iodine in excessive amounts may cause skin reactions, and it is advised that the 2 mg. dosage of vitamin K be not continued for a period exceeding four weeks.

HUMAN TUBERCULOSIS IN LEMURS

To the Editor:—I would appreciate knowing whether lemurs are susceptible to human tuberculosis. A. F. Liber, M.D., Amsterdam, N. Y.

Answer.—Herbert Fox examined at necropsy 86 lemurs and lemuridae. Twenty-three of these showed tuberculosis, an incidence of about 25 per cent. Tuberculosis of both respiratory and alimentary origin were found, but the latter was more frequent. The disease, nodular caseous or confluent caseous in type, was found in the lungs, liver, spleen and lymph nodes. The intestine, kidney and serous membranes were less often affected. No fibrotic lesions were encountered. Cobbett cultured human type tubercle bacilli from two ringtailed lemurs that had acquired the disease spontaneously. He also readily infected lemurs with bovine type tubercle bacilli experimentally. The lemur shares with primates an equal and definite susceptibility to both the human and the bovine type of tubercle bacillus.

MONILIA ALBICANS INFECTIONS

To the Editor:—Is there any effective treatment of infection with Monilia albicans involving the mouth, throat and chest? J. R. Crowder, M.D., Sullivan, Ind.

Answer.—Infections with Monilia albicans are seldom primary in nature but usually occur because the resistance of tissues is diminished by other factors such as vitamin deficiencies, infections or general debility. Treatment, therefore, should be first directed to correcting the underlying cause or causes. Specific treatment is unsatisfactory. Potassium iodide is usually advocated especially when the bronchi and lungs are involved, but there is little or no evidence of its specific value. For infections involving the oral mucous membrane mild alkaline mouth washes or solution of *gentian violet (1: 10,000)* have been used, but again without evidence of specific effect. The same may be said for vaccine prepared with Monilia.

TRICYCLE RIDING FOR FLAT FEET

To the Editor:—In the treatment of flat feet in children, would riding a tricycle with pedals shaped so that the child would have to toe in be helpful? Is there any such pedal on the market? P. J. Imperato, M.D., Brooklyn.

Answer.—There is no special pedal for the correction of flat feet. However, riding a tricycle is good exercise for children and does strengthen the foot. The most important exercise for correction of the foot is correct walking. To hold the foot in the normal position the inner side of the heel should be raised about ⅛ inch and a comma bar which is about ¼ inch higher on the outside should be placed under the anterior part of the foot.

IMPOTENCE FOLLOWING ENCEPHALITIS

To the Editor:—How long must treatment with testosterone propionate in a case of impotence following encephalitis be kept up before seeing results? Is 50 mg. three times a week the proper dose? M.D., Michigan.

Answer.—It is questionable whether the administration of testosterone propionate for impotence which follows encephalitis will be beneficial unless there is an atrophy of the testes. Twenty-five mg. of this material three times a week is a large enough dose to give. If any results are to be obtained they should be noticed after six weeks of therapy.

SPONTANEOUS SUBARACHNOID HEMORRHAGE

To the Editor:—An unmarried woman aged 43, a clerk in a store, was apparently well until three months ago, at which time she consulted her local physician. The family did not know what diagnosis was made, but the patient was appurently able to continue her work. Four days prior to admission to the hospital she arose in the middle of the night, started to cross the room and collapsed. She was found lying on the floor and was placed in bed. Her chief complaints at this time were severe headache and slight weakness of the left side. Following a convulsion she was admitted to the hospital. Temperature on admission was 99 F., pulse rate 62 and respiratory rate 16. A spinal puncture was performed immediately; the spinal fluid was grossly bloody but did not seem to be under increased pressure. However, 30 cc. of the spinal fluid was withdrawn, resulting in some diminution of the headache. Throughout the period of hospitalization considerable sedation in the form of codeine tablets hypodermically were required because of the severe headache. Blood pressure was 134/76. There was no nuchal rigidity at any time. The following day a divergent squint was noted. The eyegrounds showed no papilloedema or arterial beading. On the third day the spinal puncture was repeated. The fluid was practically unchanged in gross appearance (still bloody); the initial pressure was 170, with a rapid rise and fall in response to jugular pressure. An additional 30 cc. of fluid was withdrawn. From the second day to the time of death the temperature was almost consistently 101 F., the pulse rate 60 to 80 and the respiratory rate 14 to 18. Urine specimens were normal. Hemoglobin was 85 per cent, red blood cells 4,460,000, white blood cells 20,300, polymorphonuclear leukocytes 93 per cent. Hinton and Kolmer serologic tests (two) of the blood were normal, but of both spinal fluid specimens were 4 plus. There was no apparent increase in the white blood cells in the spinal fluid. The headache persisted and several convulsions occurred during the ten days in the hospital. Death occurred shortly after a convulsion during which the systolic blood pressure was 156. There is no definite history of hypertension or syphilis. M.D., West Virginia.

Answer.—The picture described is one of spontaneous subarachnoid hemorrhage due to a rupture of an aneurysm at the base of the brain. These aneurysms are not syphilitic and are usually due to a congenital weakness of the wall of the blood vessel. The site of rupture is frequently one of the vessels of the circle of Willis, either anterior or posterior communicating arteries. The divergent squint would indicate that the original rupture occurred at the site of the oculomotor nerve. In many instances hypertension is associated with the rupture of the aneurysm. In no instance should morphine or its derivatives be given in a case of this kind because the drug masks or produces symptoms like medullary compression. The ideal treatment is 50 per cent glucose intravenously or repeated daily spinal punctures.

DIET SHEETS

To the Editor:—Could you kindly tell me if there is any company from which I could purchase or obtain satisfactory diet sheets for various disease conditions? Jacob Levine, M.D., Bronx 58, N. Y.

Answer.—Diet sheets may be secured from a number of food manufacturing concerns. The completeness or quality of the lists must be judged by the physician. Some of the better known companies having special diet lists available are Chris

Hansen's Laboratory (Junket), Little Falls, N. Y.; the Dietene Company, Minneapolis; Kellogg Company, Battle Creek, Mich.; Ralston-Purina Company, St. Louis (allergy diets); Eli Lilly, Indianapolis (diabetic diets). The Metropolitan Life and John Hancock Insurance Companies have reducing diet lists. The American Institute of Baking, Chicago, has some special diet materials.

The Personal Diet Service, 145 West Forty-Fifth Street, New York 19, maintains a high class special diet service supplying prepared sheets. The American Dietetic Association of Chicago will soon have available a new Diet Therapy Handbook which will contain much pertinent information but no prepared sheets, of course.

HARELIP IN TWINS

To the Editor:—A woman aged 31 gave birth to twins. The first boy had a harelip on the right side and weighed 7 pounds 2 ounces (3,230 Gm.). The second boy had a harelip on the left side and weighed 5 pounds (2,268 Gm.). Is this what would be expected in a birth of this kind? These boys had separate amniotic sacs with one placenta.

Bert Anderson, M.D., Victoria, Kan.

Answer.—The question is whether or not one would expect both members of a pair of twins to have harelip if one of the pair does. Several issues are involved. First, is there any evidence of a hereditary basis for harelip? Harelip occurs sporadically in some families without any evidence of a familial tendency. Yet enough pedigrees exist which strongly suggest that hereditary factors do play a role in a majority of instances. Several pedigrees show 6 or 7 cases of harelip in two or three generations. This is a much higher incidence than would be expected if environmental factors alone were responsible. Furthermore, occurrences among twins also suggest that genetic factors frequently play a role.

Whether or not both members of a pair of twins would be expected to show harelip if one does depends to some extent on the type of the twin set that is involved. If the twin set is of the fraternal type the probability for either member of the set is the same as for any child born singly to that family. If the twins are of the one egg type the probability is great that the second member will show the abnormality if the first one does. Not enough twins with harelip have been properly diagnosed for zygosity to give exact information, but indications are that even among one egg twins one member may be free from harelip while the other one shows the defect.

The mirror imaging reported for the twins in question introduces an unsettled problem. One egg twins do tend to show mirror imaging to a greater degree than do two egg twins. Therefore, since the twins in question are of the one egg type, it is not surprising to find one member with a harelip on the left side and the other with the defect on the right.

There are questions relative to differences in incidence among sexes, mode of inheritance of harelip and the like which are of interest, but a discussion of such questions would go too far afield.

It is important to have all cases of harelip and similar defects reported in the literature. This is true especially if the defect occurs among twins or reappears in several generations of a family.

FRIGIDITY AND THE CLITORIS

To the Editor:—What is the general opinion among gynecologists as to the value of operations on the clitoris for frigidity or reduced libido? If there is an operation done for this condition what is it?

Frank E. Hyde, M.D., Beaufort, N. C.

Answer.—Operations on the clitoris or elsewhere have practically no effect on frigidity or reduced libido. The subject of frigidity has interested gynecologists, psychiatrists and psychoanalysts, who agree that in all cases of frigidity there is a large psychic element. Likewise all physicians believe that reactions of envy of men and fear of damage to the genitals play at least some part in the psychology of every girl. In many cases these are the dominating factors in personality development.

The proportion of women who derive little or no pleasure from sexual intercourse is high and has been variously estimated to be from 35 to 75 per cent. Some women not only experience no pleasure but actually suffer pain and revulsion. Greenhill (Office Gynecology, ed. 4, Year Book Publishers, 1945, p. 110) says "I should like to emphasize a point about which almost nothing has appeared in gynecologic literature. This is that in women there are actually two sexual organs. The first is the clitoris, which plays the dominant role in childhood and in masturbation during adulthood. The second organ is the vagina, which psychologically is unimportant until puberty. Whereas in the child the clitoris can and does give sexual satisfaction, in the normal adult woman it is the vagina which is the principal sexual organ. In frigid women, however, the transfer of sexual excitement and satisfaction from the clitoris to the vagina does not take place. Hence such women possess the infantile erotic zone and not the adult one."

Edmund Bergler (*Psychiat. Quart.* **18**:374 [July] 1944) maintains that a typically frigid woman suffers not from a deficiency of the libido but from a neurosis; that is, an illness of the unconscious. For this reason endocrine therapy is unsuccessful in typical cases.

Knight says "True frigidity (due to emotional factors) requires psychologic investigation following gynecologic checkup, to determine the degree of disturbance and the dynamic psychologic factors operating in the individual case. The gynecologist may attempt reeducation and reassurance, and, if these measures are ineffective, psychotherapy by a psychiatrist or psychoanalyst (preferably a man) should be recommended. Many cases of frigidity carry a good prognosis with appropriate psychotherapy. Some cases, however, are too deeply rooted in neuroses or character disorders, or desire for correction is too slight, for treatment to be effective."

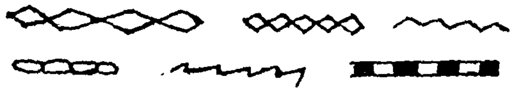
In view of the extent of the psychic factor in frigidity, operations on the clitoris are not justified.

VISUAL FATIGUE IN AUTOMOBILE DRIVER

To the Editor:—Long distance highway driving appears to tire the eyes of many drivers, and the fatigue is complained of more rapidly when the car has to follow a straight black line. This straight line leads the eye on and on, with no rest period. Has any modification of this line been tried? I should like to suggest that breaking the continuity might be helpful. Perhaps something like one of the accompanying sketches, although it would probably be more expensive than the one in use now.

Amy Weiss, M.D., Chicago.

Answer.—As far as is known, the suggestion made in the query has never been tried, but it is questionable whether following the line is a factor of any import as there are so many aspects to the problem. In all likelihood the muscle balance of the individual driver plays a greater role than do the majority of the extraneous factors. It would be of great interest to examine the ocular apparatus of drivers that complain of such fatigue in contrast to others who do not have that complaint.



Suggested modifications of continuous line.

DIAGNOSIS OF UNDULANT FEVER

To the Editor:—In Queries and Minor Notes in The Journal, Jan. 5, 1946 there is a question on the diagnosis of undulant fever. The detailed reply is unusually adequate and factual with two exceptions:

The statement that the "opsonocytophagic tests give about 3 per cent of falsely negative reactions in either the acute or chronic forms" is confusing, since it is not possible to have a "negative" opsonocytophagic test. This test is purely a relative one indicating nothing more or less than the phagocytic activity of the patient's polymorphonuclear cells at the time the test is made. A reading showing definite phagocytosis in 0 cells, moderate phagocytosis in 0 cells, slight phagocytosis in 0 cells and no phagocytosis in 25 cells too often is referred to as negative but indicates only a lack of measurable resistance to Brucella infection. Conversely a high reading, such as 19-6-0-0, cannot be called a positive test but rather one indicating a high degree of resistance. The use of the term positive or negative is particularly misleading, since the low reading (so-called negative) is usually obtained in the presence of actual infection, indicating a lack of resistance to the existing infection. If the intradermal reaction is positive and the phagocytic index is low (anything from a so-called negative to a moderate degree of resistance, such as 5-7-8-5), and if the patient exhibits symptoms presumably referable to brucellosis, a tentative diagnosis is justifiable even in the presence of negative cultures and negative blood agglutination reactions.

The other point which should be brought into question is the statement that "brucellergin intradermal tests give about 10 per cent falsely negative reactions during the initial febrile stages and are slightly more reliable in chronic illnesses." It seems a mistake to describe the intradermal test under the term "brucellergin intradermal test," since brucellergin cannot be said to be a fully acceptable skin testing antigen. Angle, Algie, Baumgartner and Lunsford tested a group of 160 inmates of a county farm, using brucellergin intradermally in one arm and heat killed vaccine in the other arm simultaneously. Positive reactions occurred in 44 brucellergin tests (27 per cent) and in 89 heat killed vaccine tests (54 per cent). The two skin testing materials were used in the same patients at the same time. The occurrence of twice the number of positive reactions to heat killed vaccine as to brucellergin would seem to indicate that heat killed vaccine is more sensitive than brucellergin as a skin testing antigen (Harris, H. J.: Brucellosis [Undulant Fever], Clinical and Subclinical, New York, Paul B. Hoeber, Inc., 1941, p. 154).

Harold J. Harris, New York.

PRIMARY LUNG TUMORS

RALPH ADAMS, M.D.
Boston

Except for 1 instance of myxochondroma and 6 cases of bronchial adenoma, this report is concerned with primary carcinoma of the lung. A diagnosis of primary carcinoma of the lung was established microscopically in 157 consecutive cases at the Lahey Clinic in the fifteen year period ended Dec. 31, 1944. The material here presented is selected only on a basis of microscopic examination because it is the only standard of reference which avoids confusion and limits controversy. A clinical diagnosis of carcinoma of the lung was made 199 times during the same period. Most of these clinical diagnoses can be accepted as accurate beyond a reasonable doubt. Terminal cases, cases judged inoperable on the basis of roentgenologic evidence and cases in which diagnostic measures failed to yield a positive pathologic report constitute the unproved portion of this group. The total figures showing 157 cases microscopically confirmed to 199 clinically diagnosed give a ratio of 1 : 1.26, or 78.9 per cent. Determination of the ratio for each year separately demonstrates that there has been little variation in the tendency to pursue the diagnosis to a morphologic answer.

Examination of the cancer statistics can best follow the line of analysis that has proved worth while with cancer of other organs, that is, on the basis of histogenesis. The way has been well marked by investigations of cancer of the rectum, cervix and breast. The problem in cancer of the lung differs only in that figures for arrest of disease must await the passage of another fifteen years. In the developmental period of pulmonary resection for cancer, lasting approximately from 1933 to 1940, the question of survival rate was partially obscured by the considerable mortality attendant on unperfected technical management, limited experience and the well remembered sequelae of bronchial leakage, pleural infection, atelectasis, chest wall mutilation and physiologic invalidism. The last four years bear witness to the practical disappearance of these complications, and, to a much larger extent, length of survival can be determined solely in terms of whether the cancer was eradicated or recurred.

Meanwhile, correlations were sought which are helpful to the solution of the problems at hand. A study of these cases presents nothing new or startling, but from it the following data have emerged.

The frequency of cancer of the lung, compared with all other cancer, is between 6 and 8 per cent. Age susceptibility is greatest between 40 and 50 years and, as indicated in table 1, the incidence follows the age incidence of malignant disease in general. The lesion was on the right side in 87 and on the left side in 70 cases.

There was a male preponderance of 128 to 29, or 81.5 per cent. Variations in the subgroups are of interest. One third of the cases of adenocarcinoma occurred in women, while either epidermoid cancer or the highly malignant oat cell cancer would appear to be almost exclusively a disease of the male.

Necropsy established the diagnosis in 5 cases (3.2 per cent), indicating need for even greater efforts to make an antemortem diagnosis (table 2). Particular attention is called to the 2 cases of metastatic carcinoma of the brain for which craniotomy was performed under the erroneous diagnosis of primary brain tumor. They give point to the facts that predominating signs and symptoms of brain tumor may obscure the underlying diagnosis of pulmonary carcinoma and that roentgenograms of the chest might wisely be included in the clinical investigation of every patient suspected of harboring a brain tumor. Adenocarcinoma of the lung is especially likely to be followed by cerebral metastases and yet in the lung is frequently "silent" because of peripheral location.

SYMPTOMATOLOGY AND DIAGNOSIS

Analysis of the symptomatology of 63 cases, found inoperable at the time diagnosis was made, shows by hindsight that a warning sign was given early in nearly all of these cases. Lack of early diagnosis was caused most often by failure of the patient to seek medical advice or by failure of the physician to consider seriously the complaint and to undertake proper diagnostic measures. The symptomatology of cancer of the lung is largely explained by bronchial encroachment, with varying degrees of obstruction or ulceration in that structure.

One hundred and forty-six patients (93 per cent) exhibited a cough, typically the first symptom, initially dry but soon productive of thin mucoid and later purulent sputum. Pain, or chest discomfort, was the second most common symptom, a complaint recorded for 85 (54 per cent) of these 157 cases. Its severity varied from a sensation of tightness in the chest to that of mild substernal oppression in intrabronchial lesions, through the many grades of pleurisy in cases of pleural involvement on to the terrible intractability associated with extension to the superior pulmonary sulcus and invasion of the brachial plexus. Sputum was present in 83 cases (53 per cent). It was only mucoid in 44, and these were the earlier cases, mostly, in which increased bronchial secretion caused by the cancer remained uninfected. It was purulent in 39 cases, indicating the presence of bronchial obstruction or secondary infection.

From the Department of Surgery, the Lahey Clinic.

Ulceration of the bronchial mucosa or tumor surface led to hemoptyses in 69 cases (44 per cent) in this series. The extent of bleeding varied from streaking or occasional spotting to actual hemorrhage. Hemoptysis of some degree every day over a period of time is one of the most positive symptoms of pulmonary carcinoma. Intermittent blood streaking is more commonly encountered, however, than is the former. One is impressed by the number of patients with this disease who readily admit cough, pain or sputum but at first deny "coughing-up of blood." Yet many will confess blood streaked sputum on one or more occasions when specifically cross questioned as to this point. This observation is probably explained by psychologic attitudes rather than by intentional concealment. To the lay mind the cough may be self explained as a "cigaret cough" and the chest wall discomfort as an attack of "pleurisy," neither of which is considered "serious." Blood spitting, on the other hand, is recognized as a sign of "serious disease" such as tuberculosis or cancer and, if only minimal in amount or sporadic in occurrence, is likely to be forgotten.

TABLE 1.—*Distribution of Carcinoma of the Lung According to Age and Sex*

Age, Years	Epidermoid		Adenocarcinoma		Oat Cell		Undifferentiated		Unclassified		Total		Total
	M	F	M	F	M	F	M	F	M	F	M	F	
20-29	..	..	..	..	..	..	..	..	..	..	..	..	..
30-39	1	2	2	..	..	..	..	1	1	..	4	3	7
40-49	15	1	3	1	4	..	3	..	6	2	31	4	35
50-59	46	1	9	..	1	1	7	4	9	5	72	11	83
60 up	16	2	1	4	1	..	3	..	..	5	21	11	32
Subtotal...	78	6	15	5	6	1	13	5	16	12	128	29	157
Total......	84		20		7		18		28				
Percentage	53.5		12.7		4.4		11.4		17.8		81.5	18.5	100

Partial encroachment to the point of incomplete obstruction, with production of a wheeze, occurred in 22 cases (14 per cent). The fleeting nature of this symptom frequently allows it to escape detection, as it disappears when bronchial obstruction becomes complete. Demonstration of localized emphysema and a unilateral wheeze, as was possible in a few of these cases, practically establishes a diagnosis of bronchial obstruction. In the roentgenograms of 26 patients (16.5 per cent) the findings were those of a tumor mass. Peripheral collapse from obstruction sufficient to prevent aeration was observed in 63 cases (40 per cent). Collapse with associated bronchiectasis from blocked egress of secretions was found in 34 cases (22 per cent). Sixteen patients (10 per cent) had an abscess cavity in the collapsed lung tissue as a result of pulmonary suppuration distal to bronchial occlusion or to actual tumor necrosis. The roentgenologic appearance of an abscess caused by central necrosis of tumor tissue is sometimes quite diagnostic, the walls of the abscess being very thick. Instead of air above a fluid level, one often sees the shadow of an ovoid mass projecting upward into the area of rarefaction. Recurrent attacks of bronchitis, pneumonitis or so-called grip frequently appeared in the clinical picture, as a reaction to the infection almost invariably a sequel to bronchial obstruction.

The five most common symptoms of cancer of the lung encountered in this group of cases, therefore, were cough, pain, sputum, hemoptysis and wheeze (table 3).

The frequency of a sixth symptom, dyspnea, recorded in 27 cases (17 per cent) was regarded with surprise until correlated with the occurrence of pleural effusion (26 cases, or 16.5 per cent). Nearly always the fluid was bloody, and microscopic examination of the stained sediment revealed carcinoma cells in 5 instances (3 per cent). Pleural effusion usually is an indication of extension or metastasis and only rarely an early sign. Nerve involvement similarly is an indication of lateness in the disease, whether exhibited by the paradoxical diaphragm of phrenic paralysis, the hoarseness and aphonia of recurrent nerve invasion, Horner's syndrome of sympathetic chain interruption or pain of cancer encroaching on the nerves of the intercostal spaces or brachial plexus. Other presenting symptoms and signs of extension of metastasis, such as weight loss, weakness, palpable nodes or involvement of other organs, either may make obvious or help to obscure the primary diagnosis, but they are of small importance from the standpoint of early diagnosis and favorable results of therapy. They indicate a situation which has already become hopeless.

Beyond a careful history and physical examination, the methods of diagnosis available for more complete study include sputum examination, roentgenography, bronchoscopy, thoracentesis, biopsy of suspected nodal metastases, bronchography, pneumothorax, thoracoscopy and lung aspiration.

Sputum examination should always be done to exclude tuberculosis. In this series of cases study of the sputum for carcinoma cells has been done only occasionally and with little enthusiasm and, perhaps in consequence, a positive diagnosis has been made by sputum examination in but 3 cases. The proper preparation of a specimen for microscopic examination is tedious and time consuming. The likelihood of any individual specimen containing cancer cells has been considered small. The possibility of error in interpretation of the many bizarre cells ordinarily found in sputum has limited confidence in the findings. However, there has been a recent resurgence of interest in sputum examination and, as a result of better technic and greater experience, better results may be obtainable.

TABLE 2.—*Diagnosis of Carcinoma of the Lung Established Only at Necropsy*

Case	Type	Clinical Diagnosis	Reason for Failure to Make Clinical Diagnosis
1	Epidermoid	Carcinoma, ? primary source	Moribund on admission; diagnosis suggested by roentgenogram; age 30+, 1936
2	Epidermoid	Myelogenous leukemia	Advanced leukemia; incidental carcinoma of right lung; age 60+, 1939
3	Unclassified	Brain tumor	Brain tumor metastatic at craniotomy; no chest symptoms or roentgenograms; age 60+, 1941
4	Epidermoid	Advanced carcinoma, ? primary source	Too ill for study; diagnosis suspected by roentgenogram; age 50+, 1942
5	Oat cell	Brain tumor	*Craniotomy; no chest symptoms* or roentgenograms; neck nodes not palpated; age 40+, 1944

A diagnosis of primary lung cancer was made by roentgenography or stated as a positive suspicion in 152 cases (96.7 per cent) and it was missed in 2 (1.3 per cent); 3 patients (2 per cent) were not examined (table 4). The reasons for no roentgenologic examination are stated under cases 2, 3 and 5 in table 2. Each of the 2 frankly misdiagnosed cases was called tuberculosis until eventually corrected by examination of tissue obtained at thoracotomy in 1 instance and bronchoscopy in another.

The radiologic features suggestive of pulmonary carcinoma are the shadow of a central or peripheral tumor mass, localized expiratory emphysema, mediastinal shift with a large amount of emphysema causing shift away from the lesion occasionally but more often toward the side of the lesion because of bronchial obstruction and atelectasis, the signs of collapse, abnormal behavior of the diaphragm and signs of mediastinal and pleural infiltration. The value of careful fluoroscopy and lateral views, in addition to posteroanterior films, cannot be overemphasized as a part of the study of problems in chest diagnosis.

TABLE 3.—*Symptomatology in 157 Cases*

	Cases	Per Cent
Cough	146	93
Pain	85	54
Sputum	83	53
Hemoptysis	69	44
Wheeze	22	14

Bronchoscopy is a helpful confirmatory procedure for lesions lying near the hilus and encroaching on major bronchi. Analysis reveals that bronchoscopy was done in 122 cases (77.7 per cent), 109 (69.4 per cent) being positive and 13 (8.3 per cent) being negative. Bronchoscopy was not done in 35 cases (22.3 per cent). A positive diagnosis was thus obtained in 89.3 per cent of the 122 cases in which bronchoscopy was carried out (table 5).

Although bronchoscopy is a relatively simple and nonhazardous procedure, it should be used selectively on a basis of seasoned clinical judgment and not employed routinely. The characteristics as shown by roentgenograms are often of value in indicating the help that may be obtained by this procedure. Rarely was a tumor seen bronchoscopically when its shadow was circular on the roentgenogram. Tumors casting such shadows nearly always are peripheral and arise beyond the major bronchi, no matter how near the midline they may look on the posteroanterior film. A lateral roentgenogram will often delineate their peripheral position in respect to the hilus. Probably the reason for their roundness is that they lie far enough peripherally to encounter equal resistance from lung parenchyma on all sides. Even tumors with the point of origin in a primary bronchus may be overlooked if growth has been outward into the hilus instead of inward into the lumen. For these reasons the presence of some degree of bronchial obstruction is almost prerequisite to diagnostic success with the bronchoscope. Of the 13 cases in which bronchoscopy was negative there were peripheral tumors in 7, an upper lobe lesion was present in 1 and in 5 cases there was no bronchial obstruction.

Suspicion of carcinoma of the lung is not in itself an indication for bronchoscopy, and many legitimate reasons exist for its omission, just as there are definite indications for its performance. Among the reasons for omission are biopsy of metastases (15 instances), advanced state of disease (8), clinical evidence sufficient for operation without it (6), a missed diagnosis clinically (3), carcinoma cells in aspirated fluid (2) and the patient's refusal (1).

Pleural effusion, as occurred in 26 cases (16.5 per cent), may be aspirated and centrifuged and the sediment stained and searched for carcinoma cells. Such cells were found in 5 instances. The thoracoscope, in conjunction with preliminary pneumothorax, is a helpful adjunct at times. Usually, if decision regarding operability cannot be made short of intrapleural visualization, open thoracotomy is believed preferable. The addition of pneumothorax alone, followed by roentgen examination, occasionally gives the required information concerning nodulation of the pleura or masses in the mediastinum. Lung aspiration with a punch biopsy needle is applicable only in the case of a peripherally placed tumor. In the few instances used, it has not led to any complications. However, hemorrhage, infection and outgrowth of a tumor along the needle tract are potential complications with this procedure which cannot be lightly disregarded. Only rarely does one require confirmation by lipiodol injection of localized bronchiectasis beyond a tumor, and much care should be exercised in its use. If the oil should be trapped by the tumor, pneumonitis will be accentuated. Experience with bronchiectasis has indicated the wisdom of waiting several weeks after bronchography before performing lobectomy to avoid the increased incidence of postoperative atelectasis which otherwise may occur. Such a time lag is unjustifiable in the treatment of carcinoma. Except in special cases, bronchography is best omitted from study of carcinoma of the lung.

Biopsy of palpable supraclavicular or axillary nodes or other metastases permitted microscopic confirmation of the diagnosis in 26 instances (16.5 per cent). The axillas and especially the supraclavicular fossae should be examined with particular care and any palpable node submitted to biopsy. Nodes lying deeply beneath the medial end of the clavicle are among the earliest involved and are very likely to escape detection unless deliberately searched for.

NONMALIGNANT TUMORS

The symptomatology and diagnostic features of the group of 7 nonmalignant tumor cases are very similar to those of the cancer series. One occurred in the third, 3 in the fourth and 3 in the fifth decade. All 7 patients were women. The lesion was on the right side in 4 and on the left side in 3 cases. All were microscopically confirmed. Five patients had a cough. Three had some chest pain or discomfort. Five had hemoptysis. Two had a wheeze. Two had mucoid sputum, and in the remaining 5 the sputum later became purulent. By roentgenograms 1 had combined signs of collapse and effusion. Four had collapse and bronchiectasis. In 1 the shadow of a tumor was visible. One had respiratory mediastinal shift and localized emphysema. The diagnosis of tumor was suggested by roentgen examination in all the cases.

TABLE 4.—*Roentgenologic Examination in 157 Cases*

	Cases	Per Cent
Diagnosis suggested	152	96.7
Diagnosis missed	2	1.3
Not examined	3	2.0

TABLE 5.—*Bronchoscopic Examination of 157 Cases*

	Cases	Per Cent
Positive	109	69.4
Negative	13	8.3
Total examined	122	77.7
Not examined	35	22.3

Bronchoscopy was positive in 5, in 1 the tumor was frankly missed and in 1 resection was justified without bronchoscopy. Bronchoscopic removal sufficed in 2.

Five required pneumonectomy. All 7 patients are living and well from 1933, 1934, 1935, 1936, 1941, 1942 and 1943 respectively.

Certain differences in these cases are noteworthy. Four had a history of at least two years' duration when first seen. General signs of morbidity were less than expected in carcinoma after similar duration. Five of the 7 patients had frequent small hemoptyses. The lung of at least 2 was functionally destroyed, and yet the patients looked fairly healthy and gave histories more consistent with chronic hemorrhagic bronchiectasis than with advanced carcinoma. The striking difference, however, is found in the results of treatment, to be discussed later.

TREATMENT

Efforts to control satisfactorily or to arrest advanced and inoperable carcinoma of the lung have been almost completely unsuccessful. Roentgen therapy has been abandoned as a curative measure. The palliation afforded is limited by the established radioresistance of this type of cancer. Temporary benefit has been obtained in several cases of the oat cell, high grade epidermoid and undifferentiated types. Noticeable reduction in the rate of fluid secretion in certain cases of pleural effusion has been observed, but rarely has the palliation lasted for more than six months. Radium has shown no advantage over x-rays, and technical considerations in its application make roentgen therapy distinctly preferable to radium.

Proved but th		

The percentage of inoperability at the time of diagnosis is discouraging. Sixty-three (40 per cent) of this group (table 6) were considered inoperable when first seen, 59 because extension or metastasis had occurred, and 4 for other reasons. These were advanced age and poor general condition, high grade of malignancy, failure to make a clinical diagnosis, and the patient's refusal. No patient was refused operation on the basis of age alone, however. The oldest patient was 72 at the time of pneumonectomy and is still working in his office a few hours daily at age 76, four years later.

Proof of extension was established in all the cases so classified, whether by symptoms and signs, biopsy of metastases or other tests. Careful examination of the visual fields of patients complaining of recent headache has been a helpful measure. Here should be emphasized the importance of perimetry with a 1 mm. object, rather than the gross finger tests often employed, to detect possible homonymous hemianopsia, nicking of the macula or other signs of cerebral metastasis.

Ninety-four cases (60 per cent) were thought operable before the thorax was opened. Liberal interpretation of operability early in the surgical study of this disease caused thoracotomy to be done in many cases that now would be recognized as inoperable on the basis of a larger experience. Part of this experience is accented by the sad immediate results of attempting to remove disease which had extended beyond the boundary line that separates the impracticable from the surgically feasible. Thoracotomy should be done in cases believed by preliminary study to be free from blood stream dissemination, direct extension into the mediastinum or pleura, implantation of cells on the pleural surface, or mediastinal nodes demonstrable by roentgenography.

Criteria of operability at thoracotomy include three of the foregoing requirements, because at this time implantation, direct extension or massive lymphatic invasion of the mediastinal nodes can be determined with greater accuracy. Forty-four patients (28 per cent) had thoracotomy only. One patient (0.6 per cent) had local excision of carcinomatous tissue invading the thoracic inlet in an unsuccessful effort to reduce pain. Nine patients died before leaving the hospital and 36 are dead or in terminal stages of the disease.

Removal of malignant disease by pulmonary resection was attempted in 49 cases, or 31.2 per cent (table 6). The type of resection to be done requires consideration of the problem of lymph node involvement, which is a disputed question. Probably the situation is similar to that of cancer of the breast, which is well understood. Any nodal involvement, as in the axilla, is a sign of grave import, but a radical mastectomy is done because some cures will result, although not as many as if the breast had been removed before any axillary metastases existed. The involvement of the supraclavicular nodes in breast cancer, however, is recognized as evidence of extension beyond the practicable range of surgery. Similarly in the lung, regional extension to the hilar nodes leaves a chance for cure by extirpation, while involvement of nodes extending upward along the mediastinum probably should place such a case in the group beyond surgical cure.

The complexity of the mediastinal lymphatic arrangement, the difference in mortality between total versus partial excision and the eventual work capacity that may be anticipated for the patient are factors favoring limited resection. On the other hand, the cancer-surgery ideal of total removal of the involved organ and mass removal of all regional lymph nodes, together with realization that early and rapid invasion of lymphatics may occur, suggests that lobectomy, the theoretical counterpart of simple mastectomy, should be less favorable than pneumonectomy. Increasing experience has demonstrated practically, however, the limited extent to which the analogy can be applied in the problem of lung cancer.

Technically speaking, pneumonectomy is not infrequently an easier procedure than lobectomy for the surgeon, but it is much harder on the patient. In this series of 49 resections there were 10 lobectomies with no hospital deaths and 39 pneumonectomies with 8 hospital deaths (20.5 per cent). To be sure, the latter figure has greatly improved since 1941. In this period there were 30 resections for carcinoma, 6 being lobectomy and 24 being pneumonectomy, with 1 hospital death (3.3 per cent). Since there was no death following lobectomy, the hospital mortality during the last four years in terms of pneumonectomy alone was 4.2 per cent. The 1 death occurred on the eighteenth postoperative day from cardiac tamponade secondary to pleural effusion and might well have been prevented by judicious use of a thoracentesis needle.

Carcinoma of the lower lobe of the lung which appears possibly curable will usually require pneumonectomy in order to excise the regional lymph nodes which characteristically extend upward along the primary bronchus and into the hilus. In upper lobe lesions the situation is somewhat different, since the lymphatic course is superior to the primary bronchus and directed toward the azygos lymph node. By upper lobectomy under these circumstances it has been possible in 4 instances to remove fully as much cancerous tissue as would have been removed by pneumonectomy. Two were palliative procedures to alleviate symptoms from sequestrating masses. One patient died within four months and 1 within one year. Two procedures were designed to remove malignant disease, and the middle lobe was also resected, as it nearly always should be because of the poorly defined fissure between the upper and middle lobes. These 2 patients are living and well for more than two years and more than three years respectively. In 6 cases a lower lobectomy was done (including the right middle lobe in 2 instances) because of peripheral location of the tumor and absence of nodal involvement in 4, and only because of emphysema and poor general condition in 2. The latter 2 patients died in five months and nine months respectively of metastatic disease. Of the other 4, 1 patient died one and a half and 1 five years later, and 2 patients are living and well four years later. Five of these 6 cases involved the right lower lobe and 1 the left lower lobe. The results of these 10 lobectomy cases are given in detail in support of a belief that, in certain carefully selected cases the retention of one lobe may be permissible without sacrificing the chances for cure, with an appreciable prevention of hospital deaths and considerable preservation of functional reserve. Of the 10 patients, 1 lived one and a half years, 1 five years, and 4 are still alive and well two years, three years, four years and four years after operation. It may be noted that this salvage rate is at least equivalent to the combined salvage with pneumonectomy included. Lobectomy, then, may be advisable for purely palliative reasons, for occasional cases of peripheral lesions with no nodal involvement arising in the lower lobe and for upper lobe lesions when the absence of infection allows removal, by mediastinal dissection, of the azygos lymph node and adjacent node-bearing tissue.

Further analysis of the 49 patients submitted to resection (31.2 per cent of 157) discloses that 8 died in the hospital (5.1 per cent), as previously stated (table 6). Twenty-three patients have died since leaving the hospital (14.6 per cent). Ten died within a year, 4 lived between one and two years, 2 lived between two and three years, and 1 lived just over five years. Four patients are living with evidence of recurrence (2.5 per cent). One patient had recurrence within one year, 2 patients within two years and 1 patient within three years of operation. Fourteen patients are living and well with a chance for five year survival (8.9 per cent). Of these patients 6 have been well for more than one year, 2 for more than two years, 4 for more than three years, 1 for more than four years and 1 for more than nine years. The microscopic slides of all these surviving patients have been reviewed and the diagnosis of carcinoma reconfirmed, as a long survival arouses suspicion that the original diagnosis might really have been bronchial adenoma. The patient now surviving for nine years, for instance, had epidermoid carcinoma with at least 3 lymph nodes involved.

Comparison of these results with those obtained in the group of 7 nonmalignant tumors of the lung again illustrates how necessary it is that end results be reported only in terms of accurate pathologic diagnoses. Operation was done on 5 of these patients and all 5 are living and well, as are 2 additional patients requiring only bronchoscopic treatment. In other words, in this series of 164 primary lung tumors the survival rate of nonmalignant tumors is 100 per cent, compared with 8.9 per cent for the malignant group.

It is believed in this clinic that the nonmalignant tumors of the lung are different entities from carcinoma of the lung, and figures concerning them are distinctly separated from the cancer statistics. However, the data are of interest in themselves and add a striking background to a differential picture of nonmalignancy versus malignancy. Bronchial adenoma and myxochondroma of the lung represent only 4.2 per cent of the proved cases of lung tumor, but 9.2 per cent of resected tumors and 33.3 per cent of arrested cases. The technical procedure required for removal may be similar or identical, but the outlook is very different for the patient.

CLASSIFICATION OF CARCINOMA

The pleomorphic nature of cancer of the lung has at times made difficult its subdivision into groups. Although the pathologic classification of carcinoma here followed of epidermoid, adeno-, oat cell, undifferentiated and unclassified carcinoma has been purely on the microscopic evidence, the clinical course, operability and results have so closely paralleled the independent pathologic grouping that they are worthy of note.

Eighty-four (53.5 per cent) of the group were epidermoid carcinoma in character. Twenty-three were inoperable. Twenty-nine were found to be nonresectable at exploratory thoracotomy. In 32 patients resection was done. Bronchoscopy was positive in 72, negative in 3 and not done in 9. Thirteen of the 14 patients living and well are in this group. The longest survival to date is nine years. Clinically the disease tends to have a slower course and these patients have greater suffering from the sequelae of bronchial obstruction than those in the other groups.

Table 7.—*Carcinoma of the Lung in 157 Proved Cases Results in 49 Resections*

	Cases	Per Cent
	49	100.0
	8	16.3
	23	46.9
	4	8.1
	14	28.5

In 20 cases (12.7 per cent) of the group the tumor was adenocarcinoma in character. Ten were inoperable. Three were found to be nonresectable at thoracotomy. In 7 resection was done. One patient is living and well. The longest survival after resection was five years. Bronchoscopy was positive in 8, negative in 4 and not done in 8. The propensity of this group toward cerebral metastasis is striking. Clinically, adenocarcinomas are likely to arise in the lung periphery and to appear as circular masses on roentgenograms.

Seven (4.4 per cent) of the group were oat cell carcinoma in character. Two were inoperable. Two were found to be nonresectable at thoracotomy. In 3 cases resection was done. The longest survival after resection was twelve months. Bronchoscopy was positive in 5, negative in 1 and not done in 1. Clinically the cases run a brief and rapid course to death. Experience has increased the ability to recognize the roentgenologic picture of broadened hilus with radiating fuzzy lines as probably oat cell carcinoma. Obvious metastases were present concurrently with the early symptoms in the 2 inoperable cases.

In 18 cases (11.4 per cent) of the group the tumors were so undifferentiated that they could not be assigned to one of the preceding groups. Eight cases were inoperable. Three were found to be nonresectable at exploratory thoracotomy. In 7 resection was done. One patient is still living with recurrence eleven months after operation and represents the longest survival following resection in this group. Bronchoscopy was positive in 9 cases, negative in 1 case and not done in 8 cases.

Twenty-eight cases (17.8 per cent) of the group for one reason or another could not be classified. Twenty were inoperable. In 8 cases the tumor was found to be nonresectable at thoracotomy. Not one was suitable for resection. Bronchoscopy was positive in 15, negative in 4 and not done in 9 cases.

It is apparent that the subgroups into which the pathologist can divide carcinoma of the lung on the sole basis of microscopic examination provide information to the clinician of great prognostic importance. The outlook for arrest of disease by resection is best in the epidermoid group and thereafter becomes progressively unfavorable through the other groups. Unfortunately the classification that is made from study of a specimen obtained at bronchoscopic biopsy not infrequently must be changed when the entire lesion is available for section and study. Furthermore, a number of cases are technically resectable in which a bronchoscopic biopsy has not been obtained. In 9 cases resection was carried out under such circumstances in this series, including 1 patient who is living and well. For the latter two reasons, the surgeon is seldom justified in withholding the only hope of saving life at the present time if the lesion is resectable on a basis of clinical judgment and experience.

TECHNICAL CONSIDERATIONS

Steady improvement in the details of management has paralleled the development of thoracic surgery in the last fifteen year period. These advances, in the main, have been concerned with preparation for operation, anesthetic administration, effective closure of the bronchus, reduction of shock, prevention of infection and atelectasis. In this section a number of technical factors are briefly outlined which are believed important in reducing the hospital mortality from 7 deaths in 19 cases of resection (36.8 per cent) in the first eleven years to 1 death in 30 cases of resection (3.3 per cent) in the last four years.

Preparation.—The water soluble vitamins are administered freely. Transfusion is given if necessary to raise the erythrocyte count above 3,800,000 and the hemoglobin above 11.5 Gm. Amino acids are prescribed orally or parenterally, as indicated, if required to raise the serum protein level above 5.5 Gm. per hundred cubic centimeters. Sulfadiazine is given in a dosage of 5 Gm. daily for at least twenty-four hours. Penicillin, since it has become commercially available, is injected in quantities of 20,000 units intramuscularly at three hourly intervals for at least fifteen hours preoperatively. Preliminary artificial pneumothorax was discontinued in the autumn of 1941 for lack of evidence that it was of significant value.

Anesthesia.—The conduct of every anesthesia in these cases is under the direct supervision of one of three experienced and highly competent anesthesiologists, although the anesthetic is actually administered in most cases by a younger physician in the course of anesthesia training. Preliminary aspiration bronchoscopy is done if secretions are abundant. The anesthetic agents used are cyclopropane, nitrous oxide or ethylene combined with ether and oxygen. Administration without exception is through an endotracheal tube connected to a closed system with arrangement for carbon dioxide absorption. Provision is made for catheter aspiration through the endotracheal tube as necessary during induction and maintenance. A bronchoscope is kept in readiness throughout the operation for use if required. The endotracheal tube is removed without hesitation and the bronchoscope employed if viscid secretions block contralateral bronchi and are not removed by catheter suction. Bronchoscopy is performed in almost every case at the completion of the operation for thorough aspiration of secretions but is done before the depth of anesthesia is appreciably lightened.

Operation.—The patient is placed on the operating table with the diseased side uppermost and one knee flexed. Pillows, sandbags or inflatable bags are not used beneath the thorax. The table is inclined to depress the head 15 degrees below the horizontal level. On occasion, the prone position is employed. A posterolateral incision is used through the periosteal bed of the fifth, sixth or seventh rib. A temporary occluding ligature is lightly tightened about the bronchus as soon as feasible after the pleural cavity has been opened. The tourniquet technic of pulmonary resection, of course, has been abandoned, and all vessels and bronchi to be divided are ligated separately. In cases of lobectomy the anatomic fissure is completed with great care to minimize injury to the remaining lobe. The pulmonary fissures, whether they are physically complete or incomplete, are maintained with striking constancy and are devoid of any important vessels or bronchi until the hilus is reached. If one will devote the essential time and patience to the task, the relatively avascular fissure can be followed into the hilus without resorting to division between clamps. All visible hilar nodes are removed, including the subcarinal and azygos lymph nodes in cases of pneumonectomy. Careful closure of the bronchus is made, the posterior membranous portion of the bronchus being infolded into the anterior cartilaginous portion with two rows of interrupted fine silk sutures, as shown in the illustration. No bronchial leakage has occurred in the 29 cases in which operation has been performed since this method has been used. The bronchus is buttressed with a pleural covering, turned as a flap, if necessary, from the chest wall. Five Gm. of sulfanilamide crystals is placed between the bronchial stump and the pleural covering before the latter is sutured in place. The chest wall is closed in anatomic layers with interrupted silk sutures. Equalized tension on pleural and periosteal sutures is achieved by use of a mechanical approximator. This holds the wound edges in constant relationship to each other until all sutures have been tied. The operated hemithorax is drained through a stab wound by means of an intercostal catheter. This is placed under 20 cm. suction, which is maintained until the patient is turned into the recumbent position. It is then clamped off. Whole blood is given during the course of the resection, 1,000 cc. usually being administered.

Postoperative Care.—The patient is transferred directly from the operating table to a bed with an oxygen tent in place. An atmosphere containing 60 to 70 per cent of oxygen is maintained constantly for the first twenty-four hours and thereafter as needed. The bed is kept in the low Trendelenburg position for the first twelve hours. The intrapleural catheter is connected to a drainage system under 15 cm. of negative pressure (measured in water) on return of the patient to the ward. The drainage is maintained until the effusion becomes serous and clear, usually in two or three days. The catheter is then removed. Sulfadiazine is given in a daily dosage of approximately 3 Gm. for five to ten days. Penicillin is given intramuscularly every three hours in doses of 20,000 to 40,000 units for ten to twelve days. The patient ordinarily becomes ambulatory on the twelfth day and is discharged on the sixteenth day after operation.

SUMMARY

Over a fifteen year period from 1930 to 1944 with 164 consecutive cases of microscopically proved primary lung tumors there were 7 nonmalignant tumors. One was a myxochondroma. Six were bronchial adenomas. There was no hospital mortality, and the 7 patients are alive and well at the present time.

There were 157 cases of carcinoma of the lung. Forty-nine patients (31.4 per cent) were submitted to surgical resection (table 7). Of the resected group, there were 8 hospital deaths (16.3 per cent). Twenty-three deaths subsequently occurred from recurrence of disease (46.9 per cent). Four patients are living with evidence of recurrence (8.1 per cent). Fourteen patients (28.5 per cent of 49; 8.9 per cent of 157) are alive and well at the present time with a chance for five year survival. The longest survival to date is nine years.

Technical procedures have reduced the hospital mortality in the last four years in 30 consecutive resections to 3.3 per cent.

605 Commonwealth Avenue.

Psychotic Breakdowns.—Paranoid reactions characterize the greater proportion of situational psychotic breakdowns occurring on the field of battle. The soldier begins to view his comrades with suspicion. Perhaps they are spies. Then he becomes convinced that certain of the officers or men are in league with the enemy. As the process accelerates, the paranoid ideas become more personal. His food, never too good in the front lines, is being poisoned. He is being sent on especially dangerous missions by an officer who is anxious to get rid of him. One sees all degrees of this type of reaction, from the mildly suspicious to the actively combative individual who views every one without distinction as an enemy and has therefore to be kept under continual restraint. Although in such cases there may appear some fear of the individuals involved in the supposed persecution, the principal reaction is one of hostility or rage.—Grinker, Roy R., and Spiegel, John P.: War Neuroses, Philadelphia, Blakiston Company, 1945.

The relationship of neurasthenia and fatigue to carbohydrate metabolism has long been of interest to investigators in psychiatry and internal medicine. Weir Mitchell[1] treated his neurasthenic patients with forced feeding among other measures and obtained good results in some instances. In 1929 Gillespie[2] studied cases of fatigue and exhaustion and found that about one third of them showed a decreased glucose tolerance in the oral test. No other observers have found hyperglycemia in fatigue, although it has been described in some of the psychoses. In 1943 Harrison and Finks[3] reported 31 cases in which hypoglycemia was a factor in the production of symptoms referable to the cardiovascular system. These symptoms appeared two or more hours after meals, were relieved by glucose, were reproduced by insulin and were usually accompanied by a low normal blood sugar. Glucose tolerance was studied by the oral method, but, as the authors stated, the rigid glucose tolerance test requirements of Conn[4] were not followed. They recommended high protein diets and intermediate feedings, which resulted in the alleviation of symptoms. Portis and Zitman,[5] Portis and Alexander[6] and Portis[7] studied the syndrome of hypoglycemic fatigue in neuropsychiatric patients in greater detail, using the intravenous glucose tolerance test developed by Soskin.[8] In their first paper they described 4 cases of fatigue which were attributed to hyperinsulinism and were treated by diets high in proteins and starchy carbohydrates and low in sugars. Atropine was also used in the therapy on the theory that temporary or prolonged stimulation of the right vagus nerve resulted from emotional processes which were relayed through the hypothalamus to the autonomic nervous system. They found that the administration of atropine

was followed by normal glucose tolerance curves in persons who had formerly exhibited flat curves. In their second paper[6] 9 similar cases were presented with a discussion of their psychiatric status. A loss of zest and revulsion against routine activities were found in these cases. It was believed that this emotional attitude caused a disturbance in the regulatory mechanisms of the blood sugar concentration resulting in acute attacks of weakness and fatigue because of increased parasympathetic tonus. Their cases were also benefited by psychotherapy, but this procedure alone was not effective in producing results. The fatigue improved completely only after dietary and drug therapy were added.

In the Army, fatigue is an important and common complaint. Because of the studies cited, we believe it advisable to investigate the carbohydrate metabolism of all patients complaining of fatigue and weakness.

METHOD

Male soldiers admitted to the psychiatric service of the hospital complaining of fatigue were utilized as the basis of the study. Physical, neurologic and psychiatric examinations were performed on all patients. The glucose tolerance of these patients was then studied. The patients were prepared for this type of study in accordance with Conn's[4] recommendations by a diet containing at least 400 Gm. of carbohydrate daily for several days prior to the test. Microchemical blood sugar tests were performed on capillary blood by the Somogyi-Shaffer-Hartmann[9] method utilizing a zinc hydroxide precipitation of proteins.[10] This method yields blood sugars which approximate true blood sugar values, with normal fasting values ranging between 60 and 90 mg. per hundred cubic centimeters. These values are approximately 20 mg. less per hundred cubic centimeters than values given by tungstic acid protein precipitation methods, the commonly used technic. Reducing substances other than glucose are responsible for this difference. The glucose tolerance test was performed as advised by Soskin,[8] using a 50 per cent solution of glucose given intravenously in the dosage of ⅓ Gm. of glucose per kilogram of body weight. In 4 cases the test was done twice. When atropine was employed, it was given one hour before the test was begun in the dose of ¹⁄₅₀ grain (1.3 mg.) hypodermically. This procedure was performed in 5 cases.

All figures are true blood sugars (normal is 60 90).

Insulin tolerance tests were done by giving ¹⁄₁₀ unit of insulin per kilogram of body weight intravenously as described by Albright. Blood sugars were then followed at fifteen minute intervals for ninety minutes. This test was performed in 3 cases.

RESULTS

(a) Symptoms.—1. Fatigue: Of 100 cases of fatigue and weakness studied, 9 were believed to be primarily caused by hypoglycemia. The main complaints in all these cases were fatigue and dizziness. Unlike the fatigue in ordinary neurasthenia, the fatigue suffered by these patients was not continuous but occurred at specified times, such as on arising in the morning or several hours after meals. It almost invariably occurred after having missed a meal. Patient 3 stated that he was weak and tired early in the morning and about ninety minutes after meals. Patient 4 had headaches and pain in the chest every morning before eating. Patient 7 always felt weak and giddy in the morning if he had not eaten. Patient 8 complained of tiredness and nervousness whenever he went without food.

2. Dizziness: All the patients complained of dizzy spells of varying degree and some also gave a history of

fainting. Patient 2 had dizziness on exertion and complained of spells in which he lost his sense of balance. Patient 4 fainted after having missed a meal. Patient 5 complained of a trembling sensation associated with weakness. Patient 7 had three fainting spells and many dizzy spells.

3. Hunger: Most of these patients spontaneously participated in frequent feedings usually not of candy but of proteins and starches. Patient 3 reported that he frequently ate between meals. If he ate during one of his attacks, the symptoms subsided within fifteen minutes. Patient 4 regularly took a few sandwiches along whenever he went on a flight lasting five hours. The condition of all the patients improved after eating.

4. Effects of Exercise: Exercise almost invariably aggravated the symptoms. Five patients reported that moderate exercise caused fatigue and dizzy spells. In case 2 (table 3) the fasting sugar fell from 81 to 59 after exercise and was accompanied by a dizzy spell.

5. Other Symptoms: Other symptoms related to the cardiovascular and gastrointestinal systems also occurred. Thus heartburn, pain in the chest and dyspnea were noted.

Only 2 of the patients showed signs of maladjustment. Patient 6 had some anxiety following combat experience overseas. Patient 9 was a generally inadequate personality. In these 2 cases it was felt that the hypoglycemia aggravated the psychiatric symptoms but was not essentially their cause. Palliation of the hypoglycemia improved the fatigue but affected the other complaints only slightly. The 7 other cases showed no significant personality deviations.

(*b*) *Laboratory Studies.*—The results of the glucose tolerance test are given in table 3. Six of the patients had flat curves. The other 3 showed the anticipated blood sugar levels after a half hour, but these values fell during the next two hours. Patient 9 went into hypoglycemic shock after one hour. In most of the cases, repetition of the test gave results similar to the first test. However, patient 5 showed a normal result on the second examination.

Three patients were given insulin tolerance tests (table 1). During these tests the patients had fatigue and dizziness similar to their usual complaints. The blood sugar in case 8 fell to 7 mg. per hundred cubic centimeters at the half hour. However, the severity of the symptoms did not depend on the degree of hypoglycemia. Thus patient 7 went into hypoglycemic shock when his blood sugar fell to 17 mg. per hundred cubic centimeters and glucose had to be administered intravenously.

(*c*) *The Effects of Atropine.*—Since atropine was reported to be beneficial in this type of case, several of the patients were given tincture of belladonna 10 minims (0.6 cc.) three times a day for seven days. None reported any improvement. Patient 3 reported that it made him worse. Five of the patients had glucose tolerance tests performed after the administration of 1/50 grain of atropine hypodermically. The results are given in table 3. In addition, 9 other patients (chronic alcoholic addicts who showed flat glucose tolerance curves but had no hypoglycemic symptoms) had glucose tolerance tests repeated after 1/50 grain of atropine. The results are given in table 4. Of the 14 cases tested with atropine, 3 showed an approximation to normal, 10 showed no change and 1, case 5, showed an intensification of the hypoglycemia after the administration of the atropine. It was therefore concluded that atropine had no effect on preventing hypoglycemia.

(*d*) *Treatment.*—The treatment used in these cases was entirely dietary. We agree with the diet advised by Portis [11] and by Harrison and Finks.[3] Diets high in proteins and carbohydrates of the more complex variety (starches rather than sugar) with frequent feedings prevented the symptoms in our cases. We did not use intensive psychotherapy. We explained to the patients the mechanism of their symptoms. This alleviated their concern about their condition.

COMMENT

We believe that hypoglycemic fatigue is a definite syndrome consisting of fatigue and dizziness after periods of abstinence from food or after exercise. There are other vague symptoms of varying degree. The syndrome can also be reproduced by the administration of insulin. The laboratory tests show glucose tolerance curves which are flat or in the course of which the true blood sugar falls to below 50. If the patient is properly prepared and true blood sugars are estimated, the blood sugar is of definite significance. This does not mean that every patient with a flat curve or low blood sugar experiences this symptom complex. However, we believe that patients with the complaints described who have flat curves have hypoglycemic fatigue. The necessary criteria can be demonstrated in only a small percentage of patients with fatigue. It is important to differentiate hypoglycemia from neurasthenia in order to institute proper therapy. In our cases atropine had no significant effect on either the results of the glucose tolerance tests or on the symptoms. We therefore do not concur in the theory that the condition is due to excessive stimulation of the vagus nerve. Alexander,[6] on the basis of psychiatric examinations, suggested that a loss of zest and revulsion to life were present in these patients and believed that this emotional attitude was responsible for the hypoglycemia via the vagus nerve. We examined the patients psychiatrically and found evidence of emotional difficulties in only 2 of them. We could find no definite relationship between the emotional state and the degree of hypoglycemia. We do believe that where hypoglycemia occurs in an unstable person it may aggravate the instability. In general, we have no theory to explain this syndrome. We wish to emphasize that the symptom complex occurs and can be recognized. We have found dietary treatment alone to be adequate and successful and recommend it in these cases. The biotropic mechanisms of some of these patients may have led them to discover it for themselves.

SUMMARY

1. In 9 cases of fatigue and dizziness due to hypoglycemia the hypoglycemia was demonstrated by the intravenous glucose tolerance test and true blood sugar determinations.

2. Dietary treatment (high proteins and complex carbohydrates) with frequent feedings was effective in alleviating the symptoms.

3. No causal relationship between the hypoglycemia and the emotional status could be found.

4. Atropine had no beneficial effect on the hypoglycemia or on the symptoms.

5. All cases of neurasthenia and fatigue should be investigated for hypoglycemia.

THE TREATMENT OF AGRANULOCYTOSIS WITH PENICILLIN

MAJOR EDWARD W. BOLAND, CAPTAIN NATHAN E. HEADLEY
and
COLONEL PHILIP S. HENCH
Medical Corps, Army of the United States

Patients with agranulocytosis do not die from the suppression of their bone marrow but from the bacterial invasion which commonly develops in the absence of granulocytes.[1] In a body robbed of its leukocytic defenses an overwhelming sepsis may occur. In such cases minor lesions of the skin and mucous membrane quickly spread and bacteria invade the blood stream. The toxemia from this resulting sepsis depresses still more the function of the bone marrow and may prevent spontaneous recovery. Pneumonia and other terminal infectious lesions precede death.

The recent development of sulfonamides and penicillin has improved greatly the treatment and prognosis of agranulocytosis. Prior to 1942 physicians attempted chiefly to stimulate the activity of bone marrow by such leukopoietic agents as pentose nucleotide, yellow bone marrow, liver extract and blood transfusions. But these remedies too frequently proved inadequate and the mortality rate in cases of agranulocytosis was high. A new policy on treatment was indorsed by Dameshek and Wolfson:[1] treatment should be directed toward the prevention and control of secondary infection rather than toward the stimulation of bone marrow activity. If infection and toxemia can be controlled, the bone marrow may take care of itself and recover spontaneously.

Thus was developed the rationale for the use of sulfonamides and penicillin, superior agents for the prevention and control of infections.

At first (between 1941 and 1943) sulfonamides or penicillin were used more often despite the presence of agranulocytosis rather than directly for it, but during the past two years (1944-1945) penicillin, becoming the remedy of choice, has been used specifically for agranulocytosis (table 1). At first most physicians did not rely on penicillin alone but used also leukopoietic agents. The earlier cases of agranulocytosis treated with sulfonamides or penicillin were caused, not by drugs, but by some overwhelming infection and bacterial toxemia. Most of the recent cases of agranulocytosis treated by penicillin have been caused by various drugs.

SULFONAMIDES FOR AGRANULOCYTOSIS

In June 1942 Dameshek and Wolfson [1] reported the successful treatment of 2 cases of agranulocytosis resulting from aminopyrine: transfusions, pentose nucleotides and liver extract were administered, but credit for the striking recoveries was given chiefly to a use of large doses of sulfathiazole. A year later Heilig and Visvewar [2] reported the successful use of small doses of sulfapyridine alone in 2 cases of "malignant leukopenia and granulocytopenia" caused by highly toxic infections of the urinary tract. Convinced of the greater importance of combating sepsis than of worrying over the bone marrow suppression, Nixon, Eckert and Holmes [3] showed considerable courage by treating 3 cases of agranulocytosis resulting from sulfadiazine (1 case unresponsive to leukopoietic agents) with further doses of sulfadiazine, the very drug responsible for the agranulocytosis: results were satisfactory, and spontaneous regeneration of granulocytes ensued.

Despite these successful results with sulfonamides, in view of the fact that sulfonamides themselves may induce agranulocytosis, physicians have turned to penicillin as an equally effective and safer remedy.

PENICILLIN IN AGRANULOCYTOSIS

The early studies on penicillin revealed that it does not embarrass leukocytic activity. Abraham, Chain and their associates [4] gave sulfapyridine to an infant with a severe pyelonephritis; granulocytopenia developed, presumably from the sulfapyridine. Penicillin and sodium bicarbonate were given orally to combat the continuing pyelonephritis. The penicillin was apparently given, not for the granulocytopenia, but despite it. The urinary tract infection disappeared and leukocytic regeneration occurred. That penicillin could be used without harm in patients with granulocytopenia or even with agranulocytosis accompanying severe infection and that the suppressed bone marrow recovered as the infection subsided was further demonstrated by Herrell and his associates.[5] A patient with severe nasal and facial cellulitis accompanied by agranulocytosis was given penicillin by Herrell;[6] as the infection subsided, the neutrophils progressively increased.

That penicillin might prove more valuable than sulfonamides for the treatment of agranulocytosis was then suggested by Dameshek.[7] Subsequently penicillin has been successfully used for agranulocytosis in 7 other cases. In the first of these cases the cause of the agranulocytosis was not stated.[8] In the remaining 6 cases the agranulocytosis resulted from drug sensitivity: from sulfonamides in 4 cases,[9] from oxophenarsine hydrochloride (mapharsen) in 2 cases [10] (table 1).

We report an additional case of agranulocytosis successfully treated with penicillin. The case was one of rheumatoid arthritis treated with gold salts, with resulting severe agranulocytosis; recovery was dramatic.

REPORT OF CASE

An officer aged 39 with chronic rheumatoid arthritis was admitted to the Army and Navy General Hospital on March 26, 1944. In August 1943 he first developed pain, tenderness and

stiffness in his left shoulder. During the next six months various peripheral joints became involved: the right shoulder, several joints of the fingers and toes, both elbows, the wrists, the knees, the ankles and the left temporomandibular joint. By March 1, 1944 he was confined to his bed or to a wheelchair and had lost 25 pounds (11 Kg.) in weight. Erythrocyte sedimentation rates, prior to his admission to the Army and Navy General Hospital, had varied between 46 and 72 mm. in one hour, and the treatment had consisted in the removal of dental foci and the use of physical therapy.

the erythrocyte count was 4,571,000 per cubic millimeter and the hemoglobin (Haden-Hausser method) was 11 Gm. The total leukocyte count was 9,300 per cubic millimeter; the differential count revealed neutrophils 58 per cent, eosinophils 4 per cent, lymphocytes 33 per cent and monocytes 5 per cent. Urinalyses were essentially normal.

The patient, who had become concerned by the rapid progress of his disease, desired to receive more aggressive treatment. Therefore he was included in a small group of patients with rheumatoid arthritis who were to be treated with penicillin.[11]

* Eleven per cent stabs; 9 per cent segmented cells.

The physical examination was essentially negative except for the articular involvement. The left temporomandibular joint was slightly tender, thickened and limited in motion. The shoulders were painful on the extremes of motion. The elbows were moderately swollen, tender and painful on forced motion; a flexion deformity of 35 degrees was present on the right, 25 degrees on the left. The wrists, several finger joints, the knees and the right ankle were moderately swollen, tender and painful on motion. Several metatarsophalangeal joints were thickened and tender. In summary, graded on the basis of 1 to 4, the patient had rheumatoid arthritis, activity grade 2 +, extension grade 3.

On admission (March 26, 1944) the erythrocyte sedimentation rate was 35 mm. in one hour (Wintrobe method, corrected); Between April 24 and May 8 (a period of fifteen days) the patient received 3,200,000 Oxford units of penicillin, given intramuscularly. No improvement resulted, nor was he benefited by a subsequent course of injections of typhoid vaccine given intravenously.

Beginning on June 1, gold salts (gold sodium thiomalate: myochrysine) were given intramuscularly once a week, 25 mg. weekly for three weeks and thereafter 50 mg. weekly. During the first ten weeks of chrysotherapy there occurred no significant alterations in the blood picture, sedimentation rates or urinalyses and no toxic reactions.

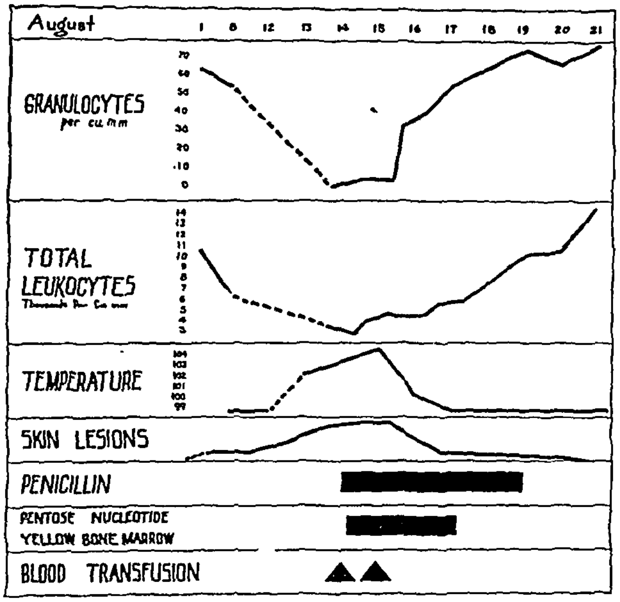
---

[11] Boland, E. W.; Headley, N. E., and Hench, P. S.: The Effect of Penicillin on Rheumatoid Arthritis, J. A. M. A. **126**: 820-823 (Nov. 25) 1944.

For almost two or three years the patient had noted mild chronic recurrent folliculitis on his back and buttocks, and a few small insignificant lesions had been present since his admission to the hospital. On August 1 the leukocyte count was 10,500 per cubic millimeter; the differential count revealed neutrophils 60 per cent, eosinophils 5 per cent, lymphocytes 29 per cent and monocytes 6 per cent (table 2). To date a total of 500 mg. of gold salts had been given.

About August 3, several small "new pimples" in the inguinal regions and right axilla were noted by the patient, who considered them to be "chigger bites." On August 8 the total leukocyte count was 6,400 per cubic millimeter; the differential count revealed neutrophils 47 per cent, eosinophils 6 per cent, lymphocytes 37 per cent and monocytes 10 per cent. Urinalysis gave normal results.

The patient's family had moved to town, and he had been permitted to live with them "in quarters." On August 12 50 mg. of gold salts was administered, bringing the total dosage of gold salts to 550 mg. within ten weeks. Following this injection the officer returned to his quarters. That evening he developed a headache and general malaise, and on the next morning (August 13) he noted many new skin lesions, "like boils," in both axillas and inguinal regions and over the medial aspect of the right arm. Although warned to report any toxic effects of gold, being in quarters and loath to be hospitalized again, he delayed in reporting these events. However, by night additional cutaneous lesions affected the legs, arms, buttocks and lower part of the back, and his headache became severe. Reporting then to the hospital, he was found to have a temperature of 102 F.



Course in hospital.

The next morning (August 14) the patient was acutely ill, with a temperature of 103.3 F., an intense headache, severe sore throat, bilateral conjunctival congestion and an extensive severe folliculitis. On the left upper gingiva a small ulceration was present; the pharynx was fiery red but exhibited no localized lesions. The cutaneous lesions now appeared as large papules surrounded by indurated erythematous halos 3 to 4 cm. in diameter. The lungs and abdomen were normal. The total leukocyte count was 3,400 per cubic millimeter; the differential count revealed no neutrophils, eosinophils or basophils; lymphocytes were 55 per cent, monocytes 45 per cent (table 2 and chart). Erythrocytes and platelets numbered 4,600,000 and 128,000 per cubic millimeter respectively; there was 13 Gm. of hemoglobin.

The total absence of granulocytes in the blood in the face of a severe, rapidly progressive folliculitis with considerable toxemia constituted a grave situation. At that time (Aug. 14, 1944), with the exception of the briefest of comment,[8] no report on the use of penicillin for agranulocytosis had appeared. Nevertheless, it seemed to us logical to use penicillin to combat the infection while we administered the usual leukopoietic remedies. Hence penicillin therapy was begun at noon on August 14. Forty thousand Oxford units was given intramuscularly every three hours for four injections, then 20,000 units every three hours day and night. Pentose nucleotide 10 cc. four times daily and yellow bone marrow concentrate 336 mg. every four hours were administered. A transfusion of 250 cc. of whole blood also was given. That evening the patient's condition was unchanged except that the progression of the cutaneous lesions was slowing. Leukocytes totaled 2,900 per cubic millimeter; the differential count revealed mature neutrophils 2 per cent, eosinophils and basophils none, lymphocytes 45 per cent, monocytes 46 per cent, unclassified cells 7 per cent.

The next morning (August 15) the patient was still critically ill. The headache was severe and his temperature ranged from 103 to 104.4 F. No new cutaneous lesions developed, and large vesicles containing clear nonpurulent fluid had developed at the crest of many of the papules. Another transfusion of 250 cc. of whole blood was given. The leukocytes totaled 3,800 per cubic millimeter; the differential count revealed 1 neutrophil, 1 eosinophil, 1 basophil, 53 lymphocytes and 44 monocytes.

The penicillin was continued, and during the next several hours a remarkable and dramatic clinical and laboratory improvement occurred, so that on the morning of August 16 (the fourth day of the acute illness) the headache was gone, the pharynx appeared normal, the gingival ulcer was almost healed and the temperature had dropped to 100 F. Whereas on the previous day we had still been greatly concerned for his life, on this day the patient was suddenly "almost well." The cutaneous lesions had changed notably: the indurated erythematous zones around the papules had disappeared completely. Several vesicles, however, had extended in size to as much as 3 cm. in diameter, and in these the vesicular fluid was now rimmed by a yellow margin of leukocytes. The leukocytes now totaled 4,100 per cubic millimeter; the differential count revealed neutrophils 20 (11 stab cells and 9 segmented cells), eosinophils 13, lymphocytes 22, monocytes 45 per cent. That evening the leukocytes totaled 4,400 per cubic millimeter; the differential count revealed neutrophils 27, eosinophils 14, lymphocytes 35 and monocytes 24 per cent.

On the next day (August 17) the patient felt fine, was afebrile and ate a hearty breakfast. The skin lesions were subsiding rapidly. Several vesicles were now filled with purulent fluid, becoming pustules as a result of the patient's improved leukocyte defense. Leukocytes totaled 5,200 per cubic millimeter; the differential count revealed neutrophils 44, eosinophils 9, basophils 3, lymphocytes 22 and monocytes 22 per cent. The administration of pentose nucleotide and yellow bone marrow concentrate was ended August 17. By August 18, four days after penicillin therapy was begun, the patient was again ambulatory and his blood picture had become essentially normal. On August 19 penicillin was discontinued after the total administration of 880,000 Oxford units in five days. No other signs of toxicity to the gold salts appeared.

For one month preceding the patient's toxic reaction to gold the arthritis had improved gradually. During the acute toxic reaction the joints improved notably; objectively they became practically normal, and for the first time in a year the patient noted no pain at rest. Eleven months after the patient's recovery from the agranulocytosis he was still much improved. It has been noted before that arthritic patients who have a rather severe toxic reaction to chrysotherapy may note unusual improvement, more so than many of those who exhibit little or no toxic reaction.

COMMENT

When gold salts are administered for rheumatoid arthritis, toxic reactions will occur in patients sensitive to gold even when the greatest caution is exerted.

Minor complications are common, and severe reactions occur in about 5 per cent of cases; the latter may result from a single injection. Agranulocytosis is one of the severe, potentially fatal reactions to chrysotherapy.

We believe that penicillin was responsible for the dramatic recovery in this case. Leukopoietic agents also were administered, but in our experience blood transfusions, liver extract, pentose nucleotide and yellow bone marrow extract have not produced such a prompt recovery.

This case again illustrates the great importance of controlling secondary bacterial infection in agranulocytosis. When infection and toxemia are controlled, the bone marrow is given a chance to recover spontaneously. Penicillin acts as a temporary substitute for the phagocytic activity of granulocytes while granulopoiesis is being resumed.

SUMMARY AND CONCLUSIONS

Since 1941 sulfonamides and penicillin have been used in the treatment of granulocytopenia or agranulocytosis. At first they were used more often despite the presence of agranulocytosis rather than specifically for it. Seven cases of agranulocytosis successfully treated with sulfonamides have been reported. But because sulfonamides may themselves produce agranulocytosis, penicillin would seem to be the remedy of choice.

Ten cases of agranulocytosis, including the 1 here reported, have now been treated with penicillin: prompt recovery has occurred in every case. This represents a notable improvement in the treatment of the condition and allows for much greater optimism in prognosis than has heretofore been possible. In some of these 10 cases leukopoietic agents were used in conjunction with penicillin, but the current trend is to rely on penicillin alone. Experiences to date indicate that penicillin constitutes the most potent remedy at hand for the prevention or control of the serious, potentially fatal complication of agranulocytosis.

Since this paper was submitted for publication another case of agranulocytosis successfully treated by penicillin has been reported. Thiouracil had been given for hyperthyroidism; the leukocyte count fell to 2,400 with 2 band cells and 2 segmented neutrophils. Treatment included a transfusion, liver extract and a total dose of 560,000 units of penicillin in four days, after which recovery was complete.[12]

Changes in Brain and Blood in Head Injury.—The brain is one of the most actively respiring organs of the body, as is evident from its abundant blood supply and the low level of oxygen in the cerebral venous blood. The more intense metabolism occurs in the gray matter, which uses oxygen in vitro about four times as fast as does white matter. It is generally recognized that glucose is the substrate of prime importance for cerebral oxidations. The brain is dependent on a constant supply of glucose from the blood, having very little reserve carbohydrate available. The respiratory quotient of the brain as calculated from arteriovenous differences is close to unity, and oxygen and glucose are taken up from the blood by the brain in approximately equivalent amounts.—Stone, W. E.; Webster, J. E., and Gurdjian, E. S.: Chemical Changes in the Brain and Gasometric Studies of the Blood in Experimental Head Injury, in Trauma of the Central Nervous System, Baltimore, Williams & Wilkins Company, 1945.

THE TEACHING OF DRUG THERAPY

AUSTIN SMITH, M.D.
Secretary, Council on Pharmacy and Chemistry
Chicago

A former President of the American Medical Association, Dr. Herman L. Kretschmer,[1] criticized the habits of physicians in writing prescriptions. The criticism provoked dozens of letters and innumerable comments, the majority offering support to Dr. Kretschmer's statements. Not all correspondents were agreed concerning the cause and cure of bad habits. Some blamed the pharmacologists; others insisted that the clinicians were at fault.

Obviously, however, many people are concerned about poor prescription writing. One well known educator wrote that the young medical practitioner dreads the writing of prescriptions because he lacks confidence that he may express his desires correctly, because he is in doubt concerning the best combinations and mixtures, and because he fears criticism from those who might observe his errors. He urges that four groups teach prescription writing: pathologists, clinicians, pharmacists and physicians who have graduated in pharmacy.

Another educator who responded to the Kretschmer article claimed that the pharmacologist should teach the action of chemicals on living things and how this knowledge may be utilized in medical practice. He also believes that the pharmacologist should give instruction in the kind of drugs to use and how to prescribe them *but that practical training in prescription writing should* be the responsibility of the clinician.

IS THERE NEED FOR RADICAL CHANGE?

Whenever an aricle concerning teaching of medical subjects is published, much discussion and correspondence are forthcoming and yet specific progressive suggestions are too infrequent, most of the comment being devoted to an expression of personal reaction to the author's communication. Many of those who are interested in the subject can and do provide useful contributions; others can, but fail to expound their own practical findings. As a result, a paper intended to provoke thought and improvement may provoke more thought and comment than actual change.

I would urge that every one who is convinced that he *knows of some useful or valuable teaching aids make* known these aids when writing to an author of or about a published article on teaching. There should be no hesitation about offering sound suggestions for improvement in medical training. Nor should there be any hesitation about initiating worth while changes even though the changes follow some one else's suggestions. Teaching carries with it a grave responsibility which simply must be met, and met *fully*. To do otherwise invites regress and a loss of progress which we have been experiencing, especially in the more recent years.

Today on all sides we hear the familiar cry "Let's change things." Medical education does not seem exempt from such pressure. This may be unfortunate if the cry is taken too seriously by those who have not yet learned that evolution is usually more satisfactory than revolution. If we look around and learn the answers to three simple questions we shall not have cause to consider truly radical changes, except perhaps in a few centers where there is actual need for much change. The answers are not always clear, but with thought we ought to be able to respond satisfactorily to these questions: What is the purpose of the subject which I am teaching? Of what does it consist? How can it be best presented?

---

[1] Kretschmer, H. L.: The Teaching of Drug Therapy, J. A. M. A. **125**: 326 (June 3) 1944.

COOPERATION IN TRAINING

There is no knowledge of greater value for the general medical profession than that concerned with drug therapy. It is used continuously by practically all physicians, regardless of specialty. There is no subject that requires more careful and continuous study. The study begins when the student is in his second year at medical school and continues until he, as a physician, retires. There is no subject in which there should be greater cooperation by teachers and practitioners with varied knowledge and interest in specialties. And yet this is one field in which cooperation is frequently lacking and confusion is rampant.

The responsibility of providing and maintaining proper knowledge in drug therapy may be divided between the medical school, the hospital and those engaged in the practice of medicine. Educational institutions should realize the fundamental value of pharmacology and therapeutics and should provide a department which permits the maintenance of pharmacology as a separate entity with adequate budget for salaries, laboratory work and research. The man who heads such a department should be well trained in the use of drugs and not some one who may be outstanding in another field but assumes the teaching of pharmacology merely because the vacancy must be filled. The value of several years' clinical experience for such a person is obvious. He should not be a part time employee, nor should he be one of those who believe that research is the only worth while activity. Research is important and plays an important role in the development of all departments and in gaining respect for the university and even from the student body. Furthermore, it is necessary if progress is to be made. However, the first responsibility of the teacher in a medical center is to the student and future physician. If a teacher must choose between his responsibility to the student and that to the institution because the latter demands that priority be given to research, he should not hesitate to pursue the obligation which he owes to those who have chosen to attend his classes. If the institution is properly organized and its directors realize the proper functions of each department, the department head and his associates will seldom, if ever, be placed in a position of having to choose between student needs and university desires; the two will be the same.

Pharmacology is usually taught in the second year in medical schools in the United States and is one of the few subjects which permit the embryo physician to realize that he is in close contact with the actual practice of medicine. Pharmacology is more than a subject. It is the basis of all materia medica which the average physician will practice in carrying out the responsibility of his chosen profession. Thus, each medical student must be taught not only to respect drug therapy but to have a keen desire to learn more about drugs so that when he graduates he will understand their action and possess a willingness to study new compounds with a view to employing those which are useful additions to the medical armamentarium and weeding out those which contribute little except confusion.

It is ruinous to provide a series of didactic lectures during which students are expected to memorize actions, uses and dosages of several hundred drugs. Instead there is needed a course which encourages the student to think, especially since the practice of therapeutics changes so quickly. Physicians must be taught to prescribe drugs for the individual case and not rely on memory for certain favorite formulas which may have been in keeping with the times several decades ago but which are now outmoded by modern chemotherapy. Teaching that the patient must be approached as an individual will result in more attentive students, better physicians and a strengthened medical school.

In these days students cannot be expected to write prescriptions in Latin and employ several systems of measure. They should be taught prescription writing in English and should learn only the metric system. Nor should students be compelled to listen to much detail about some research program in which the lecturer is momentarily interested and about which he is sufficiently enthusiastic to waste hours on details. Such data may be left for extracurricular seminars and symposiums. The pharmacology that is taught to the medical student is offered for the express purpose of aiding the physician to treat disease more efficaciously. This is different from the pharmacology that might be provided for the advanced research student who is interested in, let us say, renal physiology.

There are some problems, however, in which research is being conducted and which may be of special concern to these future physicians. The spending of extra time on the research may be advantageous when the subject includes such items as the control of a cross infection, relief of menstrual discomfort and the control of hypertension. If the student understands the reason for pharmacology and the subject is made interesting, he willingly learns the fundamentals and then asks questions which perhaps at the moment can be answered only on the basis of current research. When this man asks questions he usually wants answers so that he will know how the knowledge can be best applied in the practice of medicine.

IS THERE NOW NEED FOR EXTENSIVE TEACHING?

Sometimes one hears the argument that there is less need to teach prescription writing and pharmacology, as drug manufacturers have provided little ampules which can be broken for injection and tablets which can be given by mouth, all of them being accompanied by profusely descriptive advertising literature. It is true that manufacturers have made available more pure, more stable and more effective preparations, but no manufacturer has yet been able to offer anything which will serve as a substitute for clinical judgment. The manufacturers have done much to advance our knowledge concerning the use of drugs. They have made funds available for research. They have conducted original research and they have sought better relations with those who are best qualified to evaluate clinically new drugs. However, it should never be forgotten that the medical school is the place to lay a foundation for a knowledge of drugs. Some students feel that they can acquire their knowledge of drugs by experience and practice. Some do acquire knowledge in such a fashion, but others never acquire it because they do not possess the desire, the initiative or the fundamental training to make proper evaluation.

If a large percentage of students in any one medical center continue to harbor the belief that they can learn all that is necessary when they get in practice, it is an indication of failure on the part of the teaching staff. Either the instructors have not made clear the importance of the subject or the place which it occupies in the medical curriculum and in general practice, or the lectures have been hopelessly dull and inadequate. For example, in prescription writing classes it is not necessary to learn how to prescribe confusing and outdated complex mixtures merely for the sake of perfecting the art of prescription writing; all that will be achieved will be boredom by the class. Nevertheless there are many times when it is necessary to prescribe two or more drugs in a suitable medium, and every physician should be prepared to meet such demands. He must know what to prescribe, when and how. Evidence that discussions concerning prescriptions can be made interesting was especially apparent in one student discussion class which I visited. The person in charge of this class provided once a week a discussion of actual prescriptions written in the hospital clinics and in the wards by the attending men. Discussion was free, spirited and productive. The class was voluntarily attended, no roll call being taken, and yet absentees were few, if any.

COOPERATION IN TEACHING

In some medical schools there is much overlapping in teaching. For example, students are offered considerable detail concerning the sulfonamides and penicillin in pharmacology, medicine, obstetrics, dermatology, pediatrics and many other courses. The same is true of the hormones and other products such as serums and vaccines. If instructors from various departments have a special interest in one aspect of the subject, additional valuable teaching hours may be wasted as they expound their interest. Each instructor should recognize what preliminary training the students have had, what his associates are offering in their lecture courses and how the topics can be coordinated to the best advantage. At the same time it would be helpful if every teacher took the time and trouble to ascertain the changes which occur from year to year, so that he could estimate more effectively the advances which are occurring and bring his notes up to date every year. The students should be taught how to undertake collateral reading, where to go for their information and how to pick out what is pertinent to the subject. However, such sources of information do not necessarily provide the whole story. It is also the duty of the instructor to provide through his experience a practical interpretation of what the student reads and to give accessory information to develop appreciation of the importance of this subject.

To help the student realize that each case of illness presents a problem which requires careful thought and that it is not always an occasion for an attack with drug therapy, members of various departments should be brought into the picture. All can aid materially in teaching the proper use of drugs: For example, the pathologist can present slides of tissues on which drugs have exerted harmful effects; a representative of the Department of Public Health of Preventive Medicine can show trends of the effects of drugs on disease such as pneumonia, meningitis and typhoid or, on the other hand, on suicides and accidental deaths; the surgeon, anesthetist, radiologist, obstetrician and others can undertake similar participation. Such cooperation can be achieved during regularly assigned lecture periods, during symposiums and even by an interchange of lectures when special topics come up for discussion. For that matter, the lecturer can invite his teaching associates to join in the discussion of a special problem such as the use and misuse of the sulfonamides, of antibiotics or of arsenicals. Care must be exercised, however, to prevent the overlapping previously mentioned. This can be done by the responsible person's simply taking sufficient time to work out a joint program and to learn what his fellow instructors are doing. Such cooperative schemes can be used during the normal conduct of a course and also at its completion, and even as a refresher course in later semesters, the emphasis being placed on what is new.

Each member of a teaching unit should take a personal interest in his work and the student body. He should strive continuously for improvement, welcome suggestions and even offer suggestions to his associates when such action seems indicated. A man who is of sufficient caliber to teach should welcome suggestions without resentment; otherwise he has no place in this type of work. It is the right of the student to expect that the best will be given in lectures and demonstrations. It is the responsibility of the lecturer and the medical school to supply that which the student has a right to expect. In effect, a student and a school take upon themselves a contract when they agree to spend together four or more years for medical training. The teacher should be chosen on the basis of qualification and not merely on "good fellowship" or successful community life. Obviously a pleasing personality is a help, but the teacher must also have adequate knowledge of the subject, must recognize his responsibilities to his students and must be prepared to devote sufficient time and energy to carry out his duties in a satisfactory manner.

ORIENTATION LECTURES

In the organization of curriculums for medical schools it may help to recall that new students often have inadequate knowledge of the need for and possible application of a given subject and the relation it bears to other subjects offered in the same semester and to those in succeeding semesters. There might therefore be provided lectures intended to acquaint these men and women with the subjects they will study and the reasons for such studies. Otherwise some of the students may miss for a long time the points of the lectures and resort only to memory to obtain sufficient information to pass examinations. As the student enters a lecture course for the first time he should be provided with information concerning what he may be expected to learn and the relation it bears to other subjects in that year and in succeeding years. Such orientation lectures do not necessarily have to be given by a person in charge of the lecture course or department, although usually this would be the case. Often there are other persons who have understanding, who have good training in all subjects and who will be able to present an interesting, complete and informative picture to the student; sometimes it is necessary for several men to participate. Too frequently a student must ask during his training what value the subject is and why he should have to learn so many details. The proper understanding of the course and the part it plays in medicine and adequate organization of the course will minimize such questions.

HOSPITAL TRAINING

When a student enters a hospital as an intern he should hope for the same progressive attitude that he experienced in medical school. The training of the intern is also a cooperative and, if properly done, an extensive undertaking if the results are to be worth while. So far as the use of drugs is concerned, the intern ought to be shown an example by the experienced men on the staff and should see only the best of drug therapy. He should not be forced to use hospital formularies which list remedies by number or other equally obnoxious methods. Time after time opportunity has arisen to point out the necessity of insisting that hospital formularies contain only useful agents offered under fully descriptive names. Bad teaching policies should not be allowed to persist in hospitals simply because those responsible are indifferent to the needs of the intern. Constructive habits are especially important in this period of the young physician's life, and unsatisfactory policies should be corrected. Attending physicians who want improvement can offer much help by pointing their criticisms and entering freely into discussion with their colleagues. No physician need hesitate to suggest useful reforms. If he does hesitate, he hardly deserves the right to be a member of the medical profession. It is his duty to make his profession a better and a more informed one whenever opportunity arises.

REFRESHER COURSES

And finally, to carry the subject of drug therapy into the practitioner's life, one might point out the rapidity with which drug therapy is advancing. Today the well informed physician must be in a position to evaluate the drugs and if necessary even to expose some of those which may be foisted on his fellow practitioners and his patients. He must be aware of new and truly useful agents and he must distinguish without error between corrective and palliative treatment. At the same time he must appreciate that drugs are not the only means of successfully treating disease. Sometimes they are the most effective method; on other occasions they are merely adjuncts. Thus the up to date physician cannot depend solely on published scientific articles. Frequently he wants to hear from those who are specially trained in certain fields and who have had sufficient experience to appreciate what he needs. For those that want such knowledge there should be available courses on the use of drugs arranged at hospitals, clinics and medical schools or symposiums at county and local medical society headquarters. Such courses should be in the hands of those best qualified to give interesting and instructive presentations and not in the hands of those who are merely the most popular or aggressive. The courses should not be so long as to make them prohibitive because of living expenses or boresome because of unnecessary detail, but they should be sufficiently complete to provide the latest information. Sometimes such review courses are left in the hands of those who are extremely meticulous and much is lost because of tedious detail. The physician needs a basic knowledge of chemistry, physics, physiology, pathology and other fundamental aspects of a proper understanding of pharmacology and drug therapy, but he has no need or desire in review courses for details that are best suited for postgraduate seminars in chemistry, physics or physiology.

When one reviews the graduate continuation courses listed in the report of the Council on Medical Education and Hospitals, one is impressed by the infrequent reference to courses on therapeutics. Apparently one can with ease learn about anesthesiology, hospital administration and urology, but it is much more difficult to obtain in a teaching center comprehensive information on the use of new drugs. A short time ago the president of one of America's large drug firms stated that instead of spending millions on research the drug industry should be spending billions. One way in which some of this money could be spent effectively would be to underwrite review courses and to provide fellowships and lectureships with no strings attached. What better research can there be in drug therapy than that relating to education concerning the use of drugs? There is no point in developing "miracle drugs" if they are not properly used, and the drugs which are being developed these days require more than ever proper knowledge if they are to be used most effectively. As Dr. Roger I. Lee once said, during testimony concerning a subcommittee on health and wartime education, "Good medical care is based on good medical education, on medical research and on good medical communication. No doctor who graduated ten years ago can be a good medical practitioner solely on what he learned in the medical school. There is therefore the problem of continuing the medical education of the doctor."

Some indication of the need for this continuation of education can be gained simply by examining items available in the average pharmacy. The shelves of almost all drug stores contain packages of substances which have little or no therapeutic value. A colleague of mine, Dr. E. P. Jordan, inquired of a prescription phamacist in a Chicago loop drug store and learned that this "dead stock" is an important item to be computed in the annual store report and that probably it would be considerably higher in the ordinary drug store than in a pharmacy devoted to prescriptions. Inquiry then was made of a pharmacist in a suburban neighborhood and the inquirer learned that in this suburban store there was about $3,000 worth of dead stock which soon would have to be thrown away. Most of the items reached the store through a physician's prescription and from 70 to 80 per cent of this material probably came from smaller and less well known manufacturers. These preparations were ordered because a physician prescribed new or unusual drugs, ointments or the like but failed to use them more than once or twice. Obviously medical or direct mail advertising or the local activities of detail men were the factors largely responsible for the prescribers using these preparations before consulting such groups as the Council on Pharmacy and Chemistry or former teachers who are in a position to supply a scientific evaluation of claimed therapeutic merit. This situation results in criticism from the pharmacist, unnecessary financial expenditure by the consumer, financial loss by the druggist and frequent loss of patient confidence for the physician. It is no credit to the medical profession when pharmacists state that they can tell what detail man is calling on the doctors in their neighborhood by the type of prescriptions that begin to flow into the pharmacy.

CONCLUSION

There exist today many opportunities and challenges for advancement in rational drug therapy. The use of drugs for the prevention, diagnosis and treatment of disease is of utmost importance and requires continuous study with consideration being given to improvements in the school, the hospital and general practice. Improvements can be made only when there is thorough understanding of the problem involved and when there is complete and whole hearted cooperation among those concerned. To strive continuously for betterment in teaching and medical practice is a responsibility all serious minded physicians and teaching colleagues must recognize. To do otherwise is to shirk our duties and to invite well deserved criticism.

535 North Dearborn Street.

PENICILLIN FOR ULCERS OF LEG TREATED BY PINCH GRAFTS

RUBEN NOMLAND, M.D.
and
EVELYN G WALLACE, M D.
Iowa City

Ulcers of the leg are a perennial problem in charity hospitals because of their slowness in healing and consequent long periods of bed occupancy. For many years pinch skin grafts have been used in the dermatology service for most ulcers larger than 5 cm. in diameter because of the shortened time of hospitalization required and because the grafted area is better than the scar which results from normal healing.

In 1943 Ringrose [1] reported the results obtained with this type of graft in 29 cases treated here up to that time. The outcome was good to excellent in 80 per cent, but there was an incidence of 10.3 per cent of complete failure. The cause of failure did not become evident for some time.

Culture of the ulcers on admission, which at first was done sporadically but later became routine, indicated that the type of organism in the ulcer was important in delaying healing and in the failure of the grafts to take. Several types of organisms were found, but only two, i. e. beta hemolytic streptococcus and hemolytic Staphylococcus aureus, seemed to be the chief cause of trouble. With either one present in an ulcer the grafts usually took quite well, but if both were present poor results were the rule and complete failure was common. In most of the complete failures both organisms were present in large numbers.

The conclusion that our failures were due to infection with these organisms was reached at about the time of the publication of Ringrose's paper. We thought that surface application of antiseptics would not control the infection but that administration of a sulfonamide drug might control it. Sulfathiazole was chosen, and it was found that this drug would control the surface infection quite well when given by mouth and the results improved greatly with fewer complete failures. Sulfathiazole, given three days previous to and following application of the grafts, gave good results over a period of about two years, but one difficulty occurred: drug eruptions from sulfathiazole appeared in many of the patients, who apparently had been sensitized by local application of this drug previous to their hospitalization. Those sensitized reacted with fever and a drug eruption within twenty-four hours after starting the sulfathiazole, and it could not be continued for the requisite period of time to control the infection.

When penicillin became available it offered an opportunity to try a more effective and less toxic agent, as the organisms concerned are usually susceptible to its action. Hirshfeld and his associates [2] and also Lam and McClure [3] found that penicillin by injection greatly improved the percentage of good results in skin grafting of burns. Both felt that its action lay in its ability to control the infection in the granulating wounds. We can confirm this finding in a series of 9 cases of leg ulcers treated by application of pinch grafts in which penicillin was used before and after the grafting to control the surface infection caused by the beta hemolytic streptococcus and hemolytic Staphylococcus aureus.

The technic is not difficult and is as follows: On entrance to the ward a culture is taken and the ulcer is then bandaged with dressings kept wet with cool, one-half saturated boric acid solution. The bandages are removed only once in twenty-four hours and immediately reapplied. After four to nine days the granulations are red and bleed easily and the ulcer is ready to graft. A second culture is taken at this time and it usually shows the same organisms, especially the beta hemolytic streptococcus and the hemolytic Staphylococcus aureus, which were present on the first culture. Penicillin is then given by intramuscular injection, 15,000 units being given every three hours for a minimum of twenty-four and a maximum of forty-eight hours before grafting. Another culture is taken just before grafting, and often no organisms are found by routine culture. Small pinch or Reverdin grafts are removed from a donor area on the thigh and placed on a sterile sponge wet with isotonic solution of sodium chloride. The grafts are then placed on the ulcer. Local anesthesia has been obtained by 2 per cent procaine infiltration or by application of an ice bag containing about 30 Gm. of salt directly to the skin of the thigh. The bag is left in place approximately thirty minutes before taking the grafts, and it gives good anesthesia of about twenty minutes' duration and has been very satisfactory in the smaller ulcers. The addition of salt to the ice lowers the temperature of the bag and shortens the period needed to induce the anesthesia to thirty minutes, whereas ice alone, as recommended by Mock,[4] requires two hours. General anesthesia may be necessary with the larger lesions. When the surface of the ulcer has been covered by the grafts a dry gauze dressing, made up of about twenty layers, is bandaged firmly in place and kept from slipping by use of spiral adhesive strips. The donor area is painted with an alcoholic solution of 1.5 per cent gentian violet and left open. The painting is repeated four times a day for several days with an aqueous solution of 1.5 gentian violet.

After the skin grafting, penicillin is continued from twenty-four to seventy-two hours, depending on the apparent severity of the original infection. The bandage is routinely removed on the fifth day. Cool boric acid compresses are then used until any areas where the grafts failed to take are healed. This takes a variable period of time but seldom more than a week. Then the patient is allowed out of bed, wearing a cotton elastic bandage applied from the base of the toes to the head of the fibula. After a few days of this the patient

---

is discharged with instructions to wear the supportive elastic bandage whenever he is on his feet and to lie down, remove the bandage and rest one hour out of every four hours for several weeks.

We have treated 9 ulcers by this method. In 7 of these less than 2 per cent of the grafts were lost, in 1, 33 per cent were lost and in the other, 40 per cent. The best results were obtained in the largest ulcers.

REPORT OF CASE

The following case history is illustrative of this method:

A white man aged 68 was admitted to the University Hospitals because of an ulcer of the leg of five years' duration. The ulcer appeared two years after a simple fracture and had enlarged slowly and continuously. There was no history of typhoid or thrombophlebitis, he had no varicose veins and all pulses were palpable in this leg.

Examination revealed a large irregular ulcer on the anterior and medial surfaces of the lower half of the right leg. The ulcer measured 17 by 15 cm. in its greatest dimensions. The floor of the ulcer was covered with a large amount of greenish yellow pus, and the granulation tissue was poor. A culture on admission revealed beta hemolytic streptococcus, Pseudomonas aeruginosa and Proteus vulgaris.

The patient was placed on bed rest and cool, continuous, wet dressings of half saturated boric acid solution to the right leg. Seven days after admission the granulation tissue was bright red and bled easily (fig. 1). A culture at this time showed beta hemolytic streptococci, hemolytic Staphylococcus aureus and Pseudomonas aeruginosa. The patient was started on penicillin by the intramuscular route and was given 15,000 units every three hours for seven doses. Twenty-four hours after starting the penicillin another culture was taken which showed no growth. The ulcer was then grafted with pinch grafts and a dry dressing applied. The penicillin was continued for twenty-nine doses after the grafting was done.

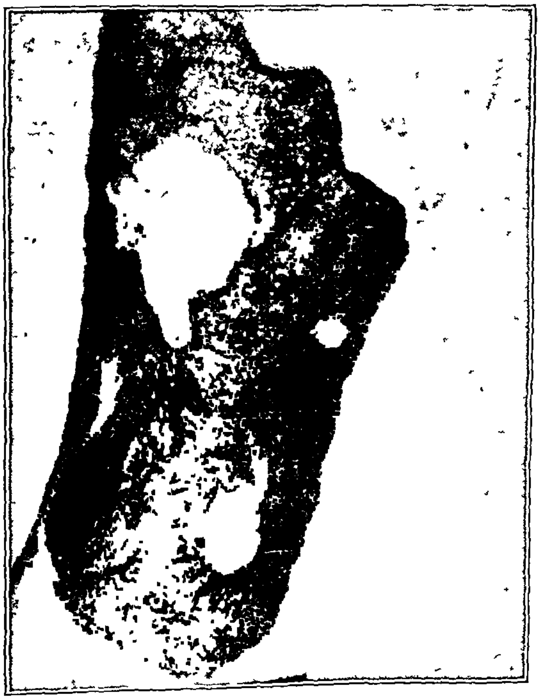

Fig 1.—Ulcer of the leg when ready for grafting

Five days after grafting, the dry dressing was removed from the grafted site and at least 98 per cent of the pinch grafts had taken (fig. 2) and the patient was discharged with the ulcer completely healed and in good condition three weeks later.

From our past experience, it is our feeling that without penicillin the pinch grafts would have failed in this case because of the size of the ulcer and because of the surface infection due to beta hemolytic streptococcus and hemolytic Staphylococcus aureus.

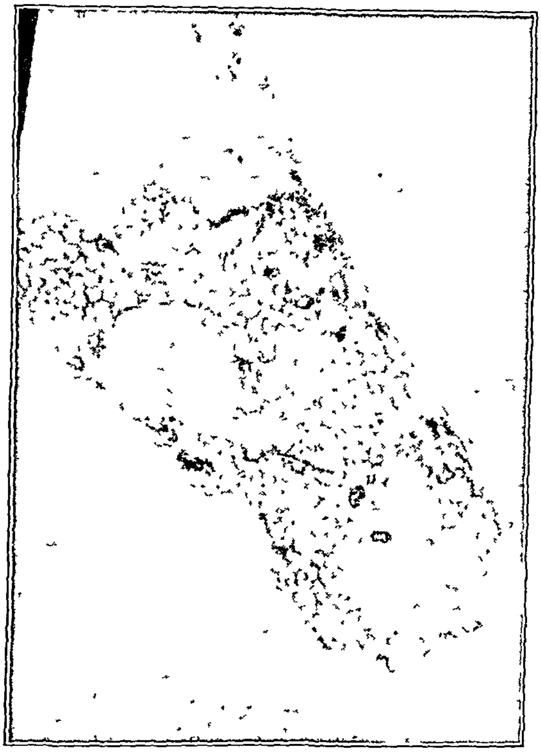

Fig. 2.—Appearance of same leg a few days after removal of bandage.

SUMMARY AND CONCLUSIONS

1. Failure of skin grafts to take in infected ulcers of the leg is apparently caused in many cases by the surface infection with beta hemolytic streptococcus and hemolytic Staphylococcus aureus.
2. Penicillin, intramuscularly, before and after grafting, has proved useful in controlling this surface infection.
3. The use of penicillin resulted in success in 9 cases of such ulcers.
4. We would recommend the routine use of penicillin intramuscularly before and after skin grafting in cases of ulcer of the leg that are treated by pinch grafts in which the surface infection is caused by the beta hemolytic streptococcus and hemolytic Staphylococcus aureus, and it could probably be used with benefit for all ulcers, irrespective of the nature of the surface infection.

Concussion States of War Neuroses.—If the postconcussive state is characterized by headaches which are relieved by lying down but made worse on stooping and by dizziness, weakness, tinnitus, decreased hearing, faulty ocular convergence, difficulty in concentration, sleeplessness and spells of faintness, we may assume that the brain has suffered injury. Unfortunately, spinal punctures are rarely performed in the early stages, so that we never obtain information regarding the presence of blood, an increase in the number of cells or elevation of the total protein in the cerebrospinal fluid.—Grinker, Roy R., and Spiegel, John P.: War Neuroses, Philadelphia, Blakiston Company, 1945.

EFFECT OF TRIDIONE IN THE CONTROL OF PSYCHOMOTOR ATTACKS

RUSSELL N DeJONG, M D.
Ann Arbor, Mich.

The manifestations of epilepsy have been classified according to the type of seizure, and grand mal, petit mal, jacksonian and psychomotor attacks are most frequently seen. This classification, however, is not entirely satisfactory. There may be a variability in manifestations from time to time; there may not be a clear-cut distinction between one type of attack and another; there may be *formes frustes* which cannot be classified, and many patients have more than one type of seizure. Furthermore, it is questionable whether petit mal and psychomotor seizures should be referred to as convulsive disorders, a term which is used more or less euphemistically as a synonym for epilepsy.

The various types of seizures listed are differentiated not only by the clinical manifestations of the individual attack but also by the electroencephalographic picture.[1] All may be classified as paroxysmal cerebral dysrhythmias. Since the advent of electroencephalography, therapy has been determined not only on the basis of the clinical picture but also on the basis of the electroencephalographic findings.

Of late many advances have been made in the treatment of epilepsy, and in the majority of cases the control of seizures is moderately satisfactory. Bromides, later phenobarbital and more recently diphenylhydantoin sodium[2] have proved to be quite effective in reducing the frequency of grand mal attacks. Surgical removal of the discharging focus plus the anticonvulsant drugs just mentioned are the measures of choice in the treatment of jacksonian or focal epilepsy.[3] The petit mal seizures yield less readily to anticonvulsant therapy. The drugs mentioned have not proved to be too helpful. A ketogenic diet has been advocated,[4] but its efficacy is doubtful. *dl*-Glutamic acid hydrochloride has also been reported to be of therapeutic benefit,[5] but this must be given in massive doses and in combination with other drugs, and our experience with it has not been encouraging. Amphetamine sulfate, caffeine, mebaral (n-methylethyl-phenyl barbituric acid) and other drugs have been used. This multiplicity of therapeutic attempts in itself suggests the difficulty in controlling the condition. Recently Lennox[6] and others have reported on the effectiveness of tridione (3,5,5-trimethyloxazolidine-2,4-dione), which has seemed to be of more benefit in the relief of petit mal seizures than any other therapeutic measure yet tried.

Psychomotor attacks, or, as they have been known for a longer period of time, psychic equivalents or variants, are likewise infrequently influenced by medication. In attacks of this type there usually are no convulsive manifestations, although there may be some tonic spasm or contortion of the trunk muscles, and the patient may stand immobile but with a slow rotation of the body. The principal characteristic of the attack consists in a period of automatic or abnormal behavior. The patient appears to be confused, and he may perform some unreasonable, unmotivated or purposeless act. He may automatically carry out a seemingly purposeful act. Frequently he is seen to mutter to himself or make chewing movements. He may void involuntarily. The degree of impairment of consciousness is variable, but the patient usually is not aware of what he is doing and has complete amnesia for what has transpired even though there is no complete loss of consciousness during the attack. The patient may become irritable or wildly violent and may commit crimes during an attack. The seizure may last for a few minutes or many hours. Dream states, fugue states and epileptic automatisms are types of psychomotor attacks. The social consequences of seizures of this sort are apparent.

Psychomotor seizures may be diagnosed not only by the clinical description of the attacks but also by the electroencephalographic picture. They are usually associated with abnormally slow waves, varying from three to six per second, often of a high voltage.[1] The electroencephalogram taken during or between attacks may show groups or series of these slow waves with broad or square tops, but with waves of the normal rhythm of from eight to ten per second still present at the crest. There may be an appearance of a positive potential which recurs at a rate of from three to six per second superimposed on an otherwise normal rhythm. The usual anticonvulsant drugs seem to have little effect on patients with psychomotor seizures. Bromides or phenobarbital may even induce amnesic or psychotic-like episodes. Diphenylhydantoin sodium has been reported to be of value,[2] as has glutamic acid,[5] but in our experience neither of these has been very effective. Patients are often incapacitated by the attacks and, as the result of the nature of the seizures, may require custodial or institutional care.

Tridione (3,5,5-trimethyloxazolidine-2,4-dione, Abbott) is an entirely new compound possessing analgesic properties. The hypnotic effects of the oxazolidine-2,4-dione derivatives were first described by Erlenmeyer.[7] These and related drugs were also found to be anticonvulsants. Everett and Richards[8] found that 3,5,5-trimethyloxazolidine-2,4-dione was the most potent analgesic in the group and that it also possessed definite anticonvulsant properties. They showed that it is effective in the control of convulsions in mice, guinea pigs, cats and rabbits produced by metrazol, strychnine, pictotoxin, thujone, cocaine and procaine

and also found that it raised the electrical threshold at which convulsions appeared in rats. They expressed the belief that it has an action comparable to that of phenobarbital but that it produces less depression in effective doses. Its acute and chronic toxicity in experimental animals was found to be very low.

In human beings, in therapeutic doses, tridione possesses analgesic and mild sedative action. It has been reported to be effective in the control of grand mal seizures, but large doses are necessary and it is probably no more effective than phenobarbital or diphenylhydantoin sodium. Some observers, however, believe that it either does not help grand mal or makes the attacks worse.[9] It has shown considerable promise in the symptomatic control of petit mal seizures when given in smaller doses.[6] Oral administration has produced nausea and skin eruptions in some patients, and others have noticed sensitivity to light, blurring of vision and change in color vision when the preparation is taken in large doses (1 to 1.3 Gm. three times a day). These disappear after discontinuation of the drug. Some patients have been said to report a feeling of light headedness and drowsiness during the first hour after ingestion.

Tridione[10] has been used in the treatment of a group of patients suffering from psychomotor attacks. In every instance the diagnosis was based both on the clinical description of the attacks and on the electroencephalographic findings. A large percentage of the patients had had attacks for many years which had failed to respond to other medical regimens. Many had grand mal and petit mal attacks in addition to the psychomotor attacks. The grand mal seizures, and sometimes the petit mal attacks, had been controlled by phenobarbital, bromides and/or diphenylhydantoin sodium, but in no instance had the psychomotor attacks been controlled by these drugs.

REPORT OF CASES

CASE 1.—L. C. B., a youth aged 16, was admitted to the University Hospital because of attacks of disordered consciousness and disturbed behavior. Since childhood he had had recurring periods of "dizziness" which were characterized by a light headed sensation and followed by "blacking out." These lasted for from a few seconds to ten minutes. He did not completely lose consciousness during them and did not fall over, and there were no motor phenomena. About six weeks before admission the patient had had a similar attack, but there was amnesia for twelve hours following it. This was succeeded by numerous seizures, which started with the dizzy sensation and "blacking out" but were followed by bizarre behavior, sometimes over a period of several hours. During these he wandered or ran about, became violent and frequently fought with people. He sometimes slumped into unconsciousness for a short time. There was always complete amnesia for the period of uncontrollable behavior, and after regaining conciousness he was fatigued. At the time of the onset of the seizures the patient was given diphenylhydantoin sodium and phenobarbital, but these medications seemed to have no effect, and at the time of his admission he was having attacks daily or more frequently. There was a history of a brief period of unconsciousness following a head injury four years previously, but the past health had been good in other respects.

The physical examination showed no abnormality aside from a mild gynecomastia bilaterally, and partial syndactyly. The neurologic and laboratory examinations, including a roentgenogram of the skull, were also negative. The intelligence quotient was 104 on the Wechsler-Bellevue scale. The electroencephalogram[11] showed a dominant picture of three to four per second medium to high voltage waves. These were flat topped, with finer components superimposed on them. They occurred serially and singly in the motor regions and in the temporomotor regions on both sides. Hyperventilation slightly raised the height of the waves and brought on a few more of the slow waves but caused no continuous slowing or high voltage bursts. There were also eight to nine per second medium voltage waves with an intermittent sinusoidal pattern, especially in the occipital region, but there were no spike and wave patterns. It was felt that the electroencephalogram showed evidence of both psychomotor and grand mal characteristics.

The patient was placed on medication with diphenylhydantoin sodium 0.3 Gm. per day and phenobarbital 0.13 Gm. per day, with no control of the episodes of disordered consciousness, and he continued to have daily seizures. He was extremely difficult to manage, and during the attacks he was belligerent and often violent. After ten days in the hospital the patient was given tridione 0.32 Gm. three times a day in place of the phenobarbital. The attacks were completely controlled on this medication and there was a decided psychologic improvement as well. Two weeks after his discharge from the hospital the patient returned, stating that he had failed to take an adequate dosage of the medication and had had another attack of disordered consciousness. Since this time, however, he has taken both preparations regularly and when last seen, four months after the tridione had been started, the patient had had but the one attack mentioned. There had been no symptoms of toxicity.

CASE 2.—C. T. H., an unmarried woman aged 28, had had attacks of disordered consciousness for five years. During these attacks the patient would stare at people and would not know what was going on about her or what was said to her. Sometimes her body would become stiff and spin about, and there were some brief movements of the extremities, but she never fell over and there was no complete loss of consciousness. She would often exhibit automatic behavior and would carry out irrelevant but seemingly purposeful acts. She would sometimes take off her clothes, even though in a public place. The patient drooled and frequently was incontinent during the attacks, and on many occasions she was aware that she had had an attack only by perceiving that she had been incontinent. She had been treated by many physicians with many types of medication, and when first seen she was taking diphenylhydantoin sodium 0.4 Gm. per day and phenobarbital 0.13 Gm. per day and was having from ten to twenty seizures a month.

The physical, neurologic and laboratory examinations, including a roentgenogram of the skull, were entirely negative. The electroencephalogram showed a dominant picture of low voltage fast activity of a rather sharp type. There were frequent two to three per second bursts of high voltage with superimposed high frequency waves. The record was interpreted as consistent with a grand mal type of disorder with psychomotor components.

The patient was placed on tridione 0.32 Gm. three times a day in addition to the diphenylhydantoin sodium and phenobarbital. She has now been on these medications for five months, and there has been just one severe attack, presumably a grand mal seizure, and two or three petit mal episodes. All of these have occurred while under unusual emotional stress. There has been a decided psychologic improvement. There have been no toxic symptoms.

CASE 3.—T. V., a married woman aged 31, had been having attacks of disordered consciousness for a period of four years. These were characterized by a transient loss of memory and confusion with automatic behavior. The patient sometimes took off her clothes during the attacks and was frequently incontinent with them. Regardless of where she was, she would want to lie down and go to sleep. There were no convulsive manifestations. The entire episode usually lasted from ten to fifteen minutes and there was complete amnesia for this period of time. The seizures occurred about three times a week. Diphenylhydantoin sodium, mebaral, phenobarbital and bromides, individually and in various combinations, had failed to control them, and these medications were difficult for her to take, as they all caused drowsiness. Diphenylhydantoin sodium in a dosage of 0.4 Gm. daily caused the development of ataxia and anorexia.

---

[9] Lennox, W. G.: Personal communication to the author.

[10] The tridione used in this study was supplied by the Department of Medicine, Abbott Laboratories, North Chicago, Ill.

[11] The electroencephalograms in this study were recorded and interpreted by Dr. Basu K. Bagchi.

The physical, neurologic and laboratory examinations, including a roentgenogram of the skull, were negative. The electroencephalogram showed many six to seven per second high voltage waves and some two to three per second high voltage waves occurring singly or serially. These frequently were cone shaped or had flat tops or jagged sides. There were also many clear and abortive spike and wave patterns of the larval type. Hyperventilation increased the height of the waves and brought on occasional three to four per second slow waves. The record was interpreted as showing evidence of both psychomotor and petit mal seizures.

The patient was placed on tridione 0.32 Gm. three times a day in addition to the diphenylhydantoin sodium 0.1 Gm. three times a day. During the first three months after the institution of this therapy there was but one attack, and there was definite psychologic improvement. On discontinuing the tridione, however, while continuing to take the diphenylhydantoin sodium, the patient experienced a recurrence of the spells and had many in the course of a few days and became quite confused. The day after the tridione was resumed the attacks stopped and the confusion and irritability left completely.

Case 4.—A. F. H., an unmarried man aged 24, had had attacks of disordered consciousness for a period of six years. These were of three types: periods of confusion lasting for but a moment, prolonged periods of amnesia during which the patient would move his arms about, show bizarre behavior and sometimes expectorate and chew his tongue, and occasional grand mal convulsions. He had been taking diphenylhydantoin sodium and phenobarbital singly and in combination, with control of the grand mal seizures but without change in the frequency of the petit mal or psychomotor attacks.

The routine physical, neurologic and laboratory examinations, including a roentgenogram of the skull, showed no abnormality. The electroencephalogram showed a moderate proportion of six to seven per second high voltage waves and two to three per second discharges with other waves superimposed on them, and there were a few abortive spike and wave patterns. Hyperventilation increased the height of the waves and brought on many serials of six to eight per second waves and occasional two to three per second waves with many spike and wave patterns. There were abnormalities characteristic of grand mal, petit mal and psychomotor seizures.

The patient was placed on tridione 0.32 Gm. three times a day in addition to diphenylhydantoin sodium 0.3 Gm. daily and phenobarbital 0.13 Gm. daily. He was then free from attacks for six weeks, until his supply of tridione was exhausted. At this time he had a return of the psychomotor seizures. On discontinuance of the phenobarbital there was a return of the grand mal seizures. Resumption of all three medications again brought about complete relief.

Case 5.—R. A. C., a married man aged 27, had had bizarre attacks for a period of one year. During these he was apprehensive, had a feeling that he was unable to breathe and would stop whatever he was doing. He would obey commands but would attempt to turn away from people. There was complete amnesia for the attacks but no loss of consciousness and no convulsive manifestations. Following the episodes the patient would feel fatigued and sleepy. A right temporosphenoidal brain abscess had been drained at the age of 9. There were no residual symptoms of this.

The physical, neurologic and laboratory examinations showed no abnormality. A roentgenogram of the skull showed an old operative defect in the right midparietal region. The intelligence quotient was 105 on the Wechsler-Bellevue scale. The electroencephalogram showed many three per second extremely high voltage waves of a sloping form. These were found in both cerebral hemispheres but were especially well defined in the right temporal region. The patient had an attack during electroencephalography, and at this time there were extremely high voltage two to three per second waves with flat tops and a few spike and wave patterns. Hyperventilation increased the height and slowness of the waves. The record suggested the presence of both psychomotor and petit mal seizures, with some evidence of definite localization in the right hemisphere.

Treatment with diphenylhydantoin sodium, bromides and mebaral was not effective in controlling the attacks. These continued to occur from twice a day to five to six times a week. The patient was placed on tridione 0.32 Gm. three times a day in addition to phenobarbital and sodium bromide, and while on this regimen he had but three petit mal attacks in a period of three weeks. The phenobarbital and bromide were discontinued, and the psychomotor spells recurred from two to four times daily. When the phenobarbital and bromide were again given with the tridione there was complete relief from the attacks.

Case 6.—W. G. H., an unmarried man aged 30, had been having attacks of disordered consciousness for twelve years. There was a history of a head injury without loss of consciousness two weeks before the onset of the spells, and a family history of epilepsy. The attacks were of two types. In one the patient was confused and exhibited peculiar behavior. "He would walk around like a drunken man" and would carry out automatic acts. There was complete amnesia for these episodes. The other attacks were grand mal convulsions. The seizures occurred from two to three times a day in spite of medication with diphenylhydantoin sodium and phenobarbital.

The physical, neurologic and laboratory examinations, including roentgenographic examination of the skull, showed no abnormality. The intelligence quotient was 98 on the Wechsler-Bellevue scale. The electroencephalogram showed a dominant frequency of six to seven per second. There were many sudden high voltage bursts of three to four per second with dicrotic notches and slightly irregular tops lasting for fifteen to twenty seconds at a stretch. Hyperventilation resulted in a rise in voltage of the regular six to seven per second frequency with admixture of three to four per second waves. Some of the waves had a superimposed high frequency pattern, and there were rare low voltage spike and wave manifestations. The recording was interpreted as showing characteristics of the psychomotor pattern with grand and petit mal components as well.

Diphenylhydantoin sodium 0.3 Gm. daily and phenobarbital 0.065 Gm. daily did not control the attacks. Diphenylhydantoin sodium 0.3 Gm. daily and triodione 0.32 Gm. three times a day also failed to control the attacks. Diphenylhydantoin sodium, phenobarbital and tridione together completely controlled the attacks during the patient's hospitalization. There was improvement in the patient's behavior. When last seen, three months after therapy with triodione had been instituted, the patient stated that the psychomotor attacks had been entirely controlled. He had, however, had a few grand mal attacks, perhaps two or three during this period of three months. When the diphenylhydantoin sodium was increased to 0.4 Gm. daily in addition to the tridione and phenobarbital the grand mal attacks also were controlled.

CONCLUSIONS

Tridione is effective in the control of psychomotor seizures. In some cases there has been a spectacular improvement. Thus far it has not proved to be sufficiently effective when used alone, partly owing to the fact that most of the patients were subject to grand mal and petit mal attacks in addition to the psychomotor seizures, and it has been found necessary to continue to control these with phenobarbital, bromides and/or diphenylhydantoin sodium, as they frequently recurred when these drugs were discontinued. The use of tridione, however, in conjunction with other anticonvulsants such as phenobarbital, bromides and diphenylhydantoin sodium, has almost completely controlled the psychomotor seizures in a large percentage of the cases and has resulted in a decided psychologic improvement.

The drug has been given by oral administration in a dosage of 0.32 Gm. (5 grains) three times a day to every patient. In this dosage no symptoms of toxicity have been reported and no contraindications or limitations to the use of the drug have become apparent.

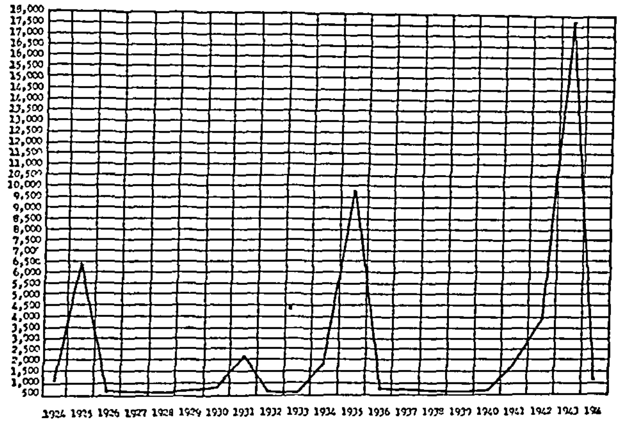
RUBELLA IN PREGNANCY CAUSING MALFORMATIONS IN NEWBORN

MAX J. FOX, M.D.
and
MORTIMER M. BORTIN, M.D.
Milwaukee

Investigation is being directed at the present time to congenital malformations of the newborn of mothers having had rubella during pregnancy. The congenital anomalies noted have been cataracts, heart disease, deaf-mutism, microcephaly, microphthalmos, atresia of the biliary ducts and renal glomerulosclerosis.

Table 1 presents most of the authors and their publications.

Gregg[1] in 1941 reported a series of 78 cases of congenital cataracts occurring in the children of mothers who had rubella from 1939 to 1941. Swan[2] investigated the problem by examination of congenitally defective children and subsequent corroboration of the rubella complication by an interview with the mothers. Swan[3] later reported further observations of rubella during pregnancy with its sequelae of congenital defects in the child. Carruthers[4] reported a high incidence of deaf-mutism, with a classification of the type, in his series of 18 cases. Reese[5] reported 3 cases of congenital cataracts and also congenital heart lesions within the first month of pregnancy. Erickson[6] in 1944 cited 11 cases in which either congenital eye or heart defects were attributable to rubella occurring in early pregnancy. Rones[7] reported 4 cases of congenital ocular abnormalities due to maternal rubella during the early months of pregnancy. Perera[8] in 1945 cited 1 case of congenital cataract with a probable cardiac lesion. deRoetth[9] in 1945 reported 2 cases of bilateral congenital cataracts with associated anomalous development.



Epidemics of rubella in Milwaukee, 1924-1944.

Most of the investigators of this timely subject based their conclusions on individual records. All of the investigators had failed to cite the total number of women having rubella in pregnancy with no congenital defects in the offspring. Each publication was based on clinical observation of the newborn infant, and the relationship to rubella during the pregnancy was in almost every instance noted in the history.

It is quite apparent that there is some relationship between these anomalies and the occurrence of this innocuous disease during pregnancy. We do not take issue on this particular point. We do feel certain, however, that the entire subject must be interpreted from a public health point of view. It is our purpose to present data covering a three year period, noting the total number of recorded cases, investigating, whenever possible, all married women having had the disease, and interviewing all pregnancy cases as to the status of the child.

EMBRYOLOGY[10]

Lens of the Eye.—The lens of the eye first appears as a thickening of the ectoderm over the developing optic cup during the fourth week. This lens placode is converted to the lens vesicle. The lens vesicle detaches from the ectoderm in the sixth week and loses its cavity by the eighth week. In association with the other structures of the eyeball, the lens reaches its typical appearance during the third month.

Internal Ear.—The primordium of the internal ear has been observed in embryos of 3 to 4 weeks. It appears from the ectoderm as the otic placode. This invaginates to form the otocyst. Differentiation of the otocyst results in the formation of the vestibular primordium and the cochlear primordium. The vestibular primordium eventually forms the semicircular canals, and the cochlear primordium forms the cochlea. This differentiation occurs at about 4 weeks and becomes distinct by 8 weeks. The essential features of the morphology of the cochlea and the semicircular canals are completed early in the third month.

TABLE 2.—*Survey 1942-1944*

	1942	1943	1944
Total number of cases	3,998	17,703	525
	73	477	31
	54	354	21
	19	123	10
Number pregnant	1	9	1

In the meantime the eighth cranial nerve has developed. The ganglions associated with the auditory nerve are formed from the neural crest at the fourth to the fifth week. They become associated with the differentiating otocyst. Early in the third month morphologic differentiation is practically complete.

Septums of the Heart.—Partition of the primitive chambers of the heart begins between 5 and 6 weeks. Development of the interatrial and interventricular septums is rapid and completed by the end of the seventh week. However, the interatrial septum is not entirely completed until the foramen ovale is closed at the time of birth.

DATA

The accompanying chart presents a series of 44,482 cases of rubella occurring in the city of Milwaukee over a period of twenty years. It will be noted that this disease occurred in epidemic proportions about every ten years. We thought it advisable to investigate the most recent years for a survey of the problem of pregnancy and rubella, and therefore we chose the years of 1942, 1943 and 1944.

Table 2 presents a total number of 22,226 cases during this time. The health department records reveal a "Mrs." in a series of 581 women during this three year survey. Of these cases we were able to investigate 152 women.

Among the 152 women investigated, 11 had rubella during their pregnancy and 5 had rubella up to the second month, 4 from the second month to the fourth month, 1 in the seventh month and another in the ninth month.

*	M. L.	..	No rubella ...		....	..	....	6/ ?/37	6/ ?/37	....	♂	Bilateral congenital cataracts

Table 3 presents the record in which in case 1 there were twins, both normal. Case 3 is the only evidence of either a coincident or direct involvement from the disease. We have purposely included the report of case 12. This case was of particular interest to us because the mother, who had rubella in her second month, gave birth to a normal child at term. In 1937 she had a normal pregnancy and gave birth to a child at that time with bilateral congenital cataracts.

COMMENT

Our approach to this subject was based on the records of the City of Milwaukee Public Health Department. Most authors on this subject reported cases seen in private practice or from a correspondence survey for congenital defects. In the event of congenital defects, further investigation for its relationship to rubella was carried out.

In our 11 cases only 1 evidenced a pathologic course. This percentage (9.09) does not concur with the statement of Swan, who claims that all mothers with such exanthems during the first two months of pregnancy will give birth to children with congenital abnormalities. It would be most proper for a well organized survey to be conducted from other health department records covering this particular subject. Incidentally, it might include a similar study of other virus diseases.

Another phase of this disease meriting a most cautious and careful approach must be considered. The question of therapeutic abortion has been suggested by the following quotations: "The justification for therapeutic abortion, if rubella occurs during the first two months of pregnancy, should be debated, since, according to Swan's figures and our own impression, 100 per cent of such babies will have serious congenital malformations."[6] "In view of the fact that, in a high proportion of cases, the contraction of rubella in the early months of pregnancy will lead to congenital defects in the infants born subsequently, it has been suggested that in such cases the pregnancy should be terminated."[2] "Should pregnant women who contract exanthemata in the first three months of pregnancy be aborted?"[5] From our records we cannot justify these conclusions. This subject is deserving of a much more intensive study than has heretofore been presented.

SUMMARY AND CONCLUSIONS

1. Rubella has occurred in the city of Milwaukee in epidemic proportions approximately every ten years.
2. In a survey of the period 1942, 1943 and 1944, 22,226 cases of rubella were reported, of which 152 married women were investigated. Of these, 11 were pregnant at the time they had rubella.
3. Of the 11 pregnant women who had rubella, the disease in 5 occurred during the first two months, in 4 during the second to fourth month, in 1 in the seventh month and in 1 in the ninth month.
4. One stillbirth occurred among the 11 cases; 1 woman had twins, both normal; 1 woman gave birth to a child with congenital cataracts during a normal pregnancy, and at the time during which she had rubella in the second month of her pregnancy she delivered a normal child.
5. Our records do not justify consideration of termination of pregnancy because of rubella.
6. The occurrence of congenital malformations in virus diseases in pregnant women is a subject deserving of further careful investigation.

Clinical Notes, Suggestions and New Instruments

COMPLETE SUBSIDENCE OF SCLERODERMA WITH DIHYDROTACHYSTEROL

EUGENE T. BERNSTEIN, M.D
and
LEWIS A. GOLDBERGER, M.D.
New York

This case of diffuse scleroderma is being reported because of the remarkable, almost dramatic response to therapy with dihydrotachysterol. The patient has been observed and treated by us for the past five years.

The clinical diagnosis of generalized scleroderma is usually not very difficult. The skin shows a boardlike thickening and appears to be stretched and hide bound. There is also a glistening with a characteristic ivory white sheen. Because of the extreme infiltration, the skin cannot be folded or picked up from the underlying connective tissues. The patient's face usually has a masklike appearance because of the tautness and increased density of the skin.

Scleroderma runs a protracted and progressive course resulting in steadily increasing disability, restriction of motion and immobility. Ulcerations, especially of the finger tips, contractures and impairment of normal physiologic functions, such as deglutition, are not uncommon sequelae.

The pathogenesis of diffuse generalized scleroderma is obscure. The disease is characterized by a progressive fibrosis which involves not only the skin but also the internal vital organs, thus making the prognosis grave. In the last decade, diffuse scleroderma was studied from the metabolic point of view and attention was focused particularly on calcium metabolism. In some cases it was found that the calcium content of the skin was increased by approximately 30 per cent. In 1927 there were introduced highly active substances affecting the calcium and phosphorus metabolism through the action of ultraviolet rays on ergosterol. The following isomers were isolated: ergosterol, lumisterol, tachysterol, calciferol, toxisterol, suprasterol I and suprasterol II. Of these, calciferol, lumisterol and the two suprasterols have been crystallized. These sterols differ from one another in their effects, only tachysterol, calciferol and toxisterol being pharmacologically active. Calciferol (vitamin D) is a potent antirachitic agent; the other two have little antirachitic value but exert powerful effects on calcium metabolism.

Holtz in 1927 attributed the toxic symptoms of hypercalcemia, produced through the administration of large doses of irradiated ergosterol, to these nonantirachitic sterols (the so-called "calcinose factor"). Through hydration or heating of the irradiated ergosterol the antirachitic factor was destroyed, whereas the toxic or serum calcium elevating factor remained. Dihydrotachysterol was obtained from unstable tachysterol by treatment with nascent hydrogen and was marketed as A. T. 10 (antitetany factor 10). By 1938 several hundred cases of low calcium diseases had been treated with uniformly good results.

REPORT OF CASE

History.—A white woman aged 70 was admitted to Mount Sinai Hospital in April 1938 because of an enlarged thyroid gland. This enlargement, about four times normal size, had existed for the past thirty-five years. On admission, a diagnosis of nontoxic goiter and chronic infectious arthritis was made. May 8, 1938 a subtotal thyroidectomy was performed and the pathologic report revealed a follicular colloid adenomatous process. The postoperative course was somewhat stormy, but eventually the patient made a good recovery.

One year later, in June 1939, the patient came to the Dermatology Outpatient Department with the following cutaneous symptoms:

1. The skin on the face, chest, abdomen and extremities had a hard, leathery appearance with ivory white and alabaster-like patches. There were also several areas of hyperpigmentation and hypopigmentation. The density of the skin was so great that it could not be picked up between the thumb and the index finger.
2. The face was infiltrated and drawn into a masklike appearance.
3. Mobility of the mouth was restricted to about half of normal, and the skin appeared to be firmly attached to the underlying structures.

The clinical picture was that of a classic case of scleroderma, and this diagnosis was confirmed by microscopic examination of a piece of skin taken for biopsy.

Treatment and Result.—On the assumption that the condition was caused by a parathyroid deficiency resulting from the thyroidectomy, treatment with dihydrotachysterol was instituted. In September 1939 15 drops were given daily and continued for eighteen days. A total of 45 cc. of dihydrotachysterol was given, after which the patient was put on a forty-five day rest period. Treatment was then resumed with a daily dose of 15 minims (1 cc.) until an additional 30 cc. had been taken. The total dosage was 75 cc. given over a period of five months. While under treatment, blood calcium and phosphorus determinations were made frequently and were always within normal limits.

The patient made excellent progress with definite somatic improvement and complete regression and recession of all physical symptoms except the maldistribution of pigment. Her skin was completely restored anatomically and physiologically. In addition, personality change occurred. From a severely depressed mental state the patient emerged with a much more cheerful outlook on life.

COMMENT

It is our impression that this patient sustained damage to her parathyroid glands during the performance of the subtotal thyroidectomy. This produced a disturbance in calcium metabolism sufficient to have resulted in scleroderma. As dihydrotachysterol is specific for disturbances in calcium metabolism, the excellent results obtained would seem to indicate that her scleroderma was parathyroprivic in origin.

SUMMARY

A case of diffuse scleroderma occurred one year following subtotal thyroidectomy for a colloid goiter. On the assumption that the scleroderma arose because of a disturbance in calcium metabolism secondary to surgical injury of the parathyroids, dihydrotachysterol was administered, with almost dramatic response.

PAIN IN THE PERFORATING TYPE OF PEPTIC ULCER

ARNOLD H. KADISH, M.D.
Fellow in Medicine, Mayo Foundation
and
ANDREW B. RIVERS, M.D.
Rochester, Minn.

Moynihan once said that peptic ulcer could be diagnosed over the telephone. He pointed out that duodenal ulcer is likely to produce the typical "food-comfort-pain" picture whereas gastric ulcer is more prone to cause the typical "food-comfort-pain-comfort" syndrome. All physicians are familiar with the classic picture of recurrent episodes of epigastric burning, gnawing or hunger distress which begin from half an hour to several hours after meals and are eased by food or soda. The telephonic diagnosis of peptic ulcer would go far amiss if it should be employed in cases of complicated peptic ulcer. Although it is true that uncomplicated peptic lesions involving stomach, duodenum or anastomatic stoma follow the usually accepted pattern so well described by Moynihan, it is equally true that the more serious the complication the less stereotyped and clocklike are the symptoms caused by such lesions. Change from the accepted pattern is particularly true of penetrating types of peptic ulcer.

When such ulcers begin to invade the wall of the viscus more deeply so that serosa and contiguous tissues are involved,

---

From the Division of Medicine, Mayo Clinic.

the pain becomes more severe, relief following the ingestion of food or soda is less prompt and adequate and there is more associated tenderness. The usual "food-comfort-pain" or "food-comfort-pain-comfort" cycles become distorted or are obliterated entirely. Furthermore, under such conditions varying shifts of pain into secondary regions are common. Our object in this report is to lay emphasis on the great variability of the pain under such circumstances.

Gastric ulcers often will produce pain or distress which is felt in the left side of the epigastrium. The pain may be referred laterally to the back or extend through to the back. The pain in the back, which may be extremely severe, is felt more frequently to the left than to the right of the lower thoracic portion of the spinal column. Pain extending into the left shoulder and neck is evidence of deep penetration of the ulcer with involvement of tissue with phrenic innervation.

The pain of duodenal ulcer is felt in the pit of the stomach or to the right of the midline just above the umbilicus. If the pain extends to secondary regions, it usually extends to the right costal region, into the thorax or around to the back. When the pain is severe, it may extend through to the back. Localization of the dorsal pain is usually at the level of the ninth and tenth thoracic vertebrae to the right of the spinal column.

Shift of pain due to duodenal ulcer to the left usually indicates penetration of the pancreas, a bilaterally placed organ. It is our belief that when ulcer invades tissues supplied by spinal nerves the pain often may be interpreted as being felt along the superficial, highly differentiated branches of these same nerves; for example, along the distribution of the intercostal nerves.

REPORT OF CASE

A white man aged 38 entered the Mayo Clinic on Feb. 3, 1944 and was hospitalized immediately. He stated that he had been well until 1926, at which time an epigastric gnawing sensation began one to two hours after meals. This distress was relieved by milk and by soda. Attacks lasting several days to a week occurred several times each year, but neither vomiting nor melena was associated. Posterior gastrojejunostomy performed in 1929 gave relief of pain until 1931, when it returned in more severe form with penetration to the back. Thereafter several increasingly severe attacks occurred each year until 1938, when roentgenograms revealed a gastrojejunal colic fistula. At operation closure of the colon, resection of the jejunum with end to end anastomosis and gastroduodenostomy were accomplished. The patient stated that since this operation he had had no further ulcer distress.

The illness which brought the patient to the clinic began in the spring of 1940 with pain in the right lower part of the chest. There was no abdominal pain. The pain was a hot, burning pain which would start either anteriorly or posteriorly and extend in either direction. It was skin deep. It was not related to meals. On some occasions hot coffee would ameliorate it somewhat but never would eliminate it completely. This pain had been present save for an occasional day almost continuously since onset. On one occasion it had been relieved temporarily by injection of the intercostal nerves with procaine.

A modified Sippy type of management was employed for two weeks after the patient was admitted to the hospital, with no relief at any time. Laboratory examination of the blood revealed hemoglobin 15.8 Gm. per hundred cubic centimeters of blood, leukocytes 11,800 per cubic millimeter of blood, blood urea 40 mg. per hundred cubic centimeters and sedimentation rate of erythrocytes 21 mm. per hour (Westergren). An occasional leukocyte and erythrocyte were noted in the urine; the guaiac test on the stool was negative (1 specimen) and spinal fluid was normal. Gastric analysis before treatment revealed a total acidity of 72 and a value for free hydrochloric acid 62 (Töpfer's method); 130 cc. of gastric content was obtained. After ten days of the Sippy treatment total acidity was 24, free hydrochloric acid was 14 and 150 cc. of contents was obtained. Results of gastric analysis were within normal limits in other respects. Roentgenograms of the chest, gallbladder, thoracic portion of the spinal column and colon and an excretory urogram revealed no abnormalities. Roentgenologic examination of the stomach, however, revealed considerable deformity, especially at the outlet.

Because the patient failed to improve under medical management for ulcer, despite decrease in gastric acids, injection of the sixth to eighth thoracic nerves on the right side with procaine was carried out. Within fifteen minutes the patient experienced remarkable relief, which lasted throughout the night so that he was able to sleep well, which was then truly unusual for him. However, because it was felt that the pain probably was referred from a perforating duodenal ulcer, exploratory operation was carried out. A huge duodenal ulcer was found on the anterior and lateral wall of the second portion of the duodenum. The ulcer was perforating onto the gallbladder, which formed its base. Partial gastrectomy and partial duodenectomy were carried out.

COMMENT

In this case of recurrent duodenal ulcer there were no abdominal complaints, but pain was present in the right lower portion of the chest. It should be emphasized that pain in cases of recurring ulcer may have no relation to meals, may not be relieved in the usually accepted manner and may be referred to regions remote from the abdomen. Furthermore the clinical impression in these cases must ofttimes be relied on when the roentgenologic studies reveal no evidence of recurring ulceration.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin Smith, M.D., *Secretary.*

PROCAINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1945, p. 97).

The following additional dosage forms have been accepted:

The Wm. S. Merrell Co., Inc., Loeser Laboratory Division, New York

Solution Procaine Hydrochloride 1% W/V: 30 cc. and 100 cc. Each cubic centimeter contains procaine hydrochloride 10 mg. in isotonic solution of sodium chloride with chlorobutanol 0.5 per cent as a preservative.

Solution Procaine Hydrochloride 2% W/V: 30 cc. and 100 cc. Each cubic centimeter contains procaine hydrochloride 20 mg. in isotonic solution of sodium chloride with chlorobutanol 0.5 per cent as a preservative.

PERTUSSIS VACCINE COMBINED WITH DIPHTHERIA AND TETANUS TOXOIDS (See The Journal, Jan. 5, 1946, p. 31).

The following dosage form has been accepted:

Sharp & Dohme, Inc., Glenolden, Pa.

Diphtheria-Tetanus-Pertussis Antigens Combined, Alum Precipitated: One 3 cc. vial (one 3 dose immunization) and one 10 cc. vial (three 3 dose immunizations). Preserved with phenylmercuric nitrate 1:50,000.

DIETHYLSTILBESTROL (See New and Nonofficial Remedies, 1945, p. 428).

The following dosage forms have been accepted:

Carroll Dunham Smith Pharmacal Company, Orange, N. J.

Diethylstilbestrol (in Peanut Oil): 1.0 mg. per cc.: 1 cc. ampuls.

Tablets Diethylstilbestrol: 0.1 mg., 0.5 mg., 1.0 mg. and 5.0 mg.

PENICILLIN (See New and Nonofficial Remedies, 1945, p. 214).

The following dosage form has been accepted:

Winthrop Chemical Co., Inc., New York

Penicillin Calcium: Vials containing 100,000 or 200,000 units.

SATURDAY, MARCH 2, 1946

THE TREATMENT OF SHOCK FROM PROLONGED EXPOSURE TO COLD

Sometime ago THE JOURNAL commented editorially on the experiments by the German Professor Weltz, who had accidentally discovered that rapid warming in water of 104 to 113 F. was life saving to guinea pigs and hogs that had been chilled to the threshold of death. Now the discovery of the entire contents of Himmler's cave in Hallein placed in Allied hands a number of secret S. S. records. These are the basis of a report by Major Alexander.[1] The letters convey a complete account of the organization and administration of the experiments on human beings performed by Dr. Rascher, assisted by his wife, Nini, who was formerly secretary and mistress of Himmler. Dr. Rascher proposed to Himmler experiments on human beings in the concentration camp of Dachau. Persons were cooled until the intragastric temperature was reduced to 79.5 F. and the rectal temperature to 79.7 according to thermoelectric measurements. Fatalities occurred only among the groups in which the bodies were immersed in such a position that they covered the occiput and thus affected the brain stem and the hind brain. Necropsies of such cases always revealed free blood up to 0.5 liter in the cranial cavity; the heart invariably showed dilatation, especially of the right chamber. These subjects died as soon as the rectal temperature reached 82.4 F. despite all attempts at resuscitation. Other important observations were an increase of the viscosity of the blood, increase of hemoglobin, increase of leukocytes and a rise of blood sugar to twice its normal value. Auricular fibrillation made its appearance regularly at 86 F. rectal temperature. During attempts to save severely chilled subjects, rapid rewarming was proved in all cases preferable to slow rewarming. Even after removal from the cold water the temperature of the body tended to sink rapidly. The experiments have also shown the inefficacy of pharmaceutic measures as well as of rewarming by animal warmth, that is, by animal bodies or women's bodies.

An interesting document is Professor Hippke's letter of thanks to Himmler in which he expresses his appreciation for the great assistance provided by the Dachau experiments with human beings and his hope that other problems, namely the combination of low pressure and extreme cold, would be solved in a similar manner in the future. There must have been some mild opposition on the part of the more decent scientists to this method of investigation, as is evident from the remark by Himmler in a letter to Dr. Rascher: "People who today still disapprove of experiments on human beings, but who prefer to let brave German soldiers die from the consequence of intense cold, are to me nothing but traitors to their country and I shall not hesitate to supply the names of these people to the authorities who are in a position to take action against them." According to the report, Nov. 5, 1942 four inmates of the concentration camp for women in Ravensbrück were turned over to Dr. Rascher and his staff in Dachau. They were not supposed to be used as subjects in the chilling experiments but merely as a means of rewarming male subjects used in such experiments. In another report to Himmler Rascher stated "Up to the present I have carried out intense chilling experiments on 30 human beings by leaving them outdoors naked from nine to fourteen hours, thereby reducing their body temperatures to 27 C. [80.6 F.]. In all experiments up to the present, all subjects, despite the fact that hands and feet were partly frozen white, were successfully rewarmed within another hour." He also makes a request that he be transferred to Auschwitz, where he "could clear up the question of rewarming people frozen on dry land in a large serial experiment." In another experiment people were kept naked outdoors for fourteen hours at a temperature of 21.2 F.

Rascher and his wife were executed by shooting in April 1945, two weeks before the arrival of the Americans, on the order of Himmler, who considered Rascher too talkative and hence a dangerous source of information if he fell alive into Allied hands. A relatively small percentage of fatalities occurred among prisoners who were used for malaria experiments. However, the report indicated that there were a great number of unnecessary casualties because of the crude manner of performing experimental liver punctures by a certain Dr. Brachtl. In general, human subjects for experimental purposes were selected from the inmates of the camp in the following order: first Jews, then foreigners, Gipsies, stateless prisoners, foreign Catholic priests, professional criminals and finally political prisoners. Such group distinctions between prisoners, expressed in the form of special badges, were made in order to create group rivalry and disunity among the prisoners.

The report lists all of the participants and witnesses for the convenience of the war crime authorities, because they may find that the manner in which these experiments were performed constituted a war crime. Dr. Rascher wallowed in blood and in obscenity, allowing frozen people to die in bed with naked women in order to demonstrate the relative ineffectiveness of that method of rewarming, while standing ready to measure the rectal temperature of those who recovered sufficiently to carry out sexual intercourse under those circumstances.

---

[1] Alexander, Leo: The Treatment of Shock from Prolonged Exposure to Cold, Especially in Water (Report 250), Office of the Publication Board, Department of Commerce, Washington, D. C.

Out of this revolting mess of sadistic cruelty and obscenity, participated in not only by men of Rascher's caliber but by a number of men once important in the German scientific world, came a single practical suggestion, namely that rapid rewarming is more effective in the treatment of shock due to chilling than slow rewarming. Even that suggestion was not original, for it was advocated as far back as 1880 by a Russian physician.[2]

AMYOTONIA CONGENITA (OPPENHEIM), A RARE BUT IMPORTANT ENTITY

While only 200 cases of amyotonia congenita are on record,[1] practical considerations demand a clear conception of the pathologic processes involved in this disease and its twin, Werdnig-Hoffmann's progressive muscular atrophy. The physician must be prepared to advise the anxious parents of a child with amyotonia congenita regarding the possibility of the occurrence of the disease in other children who may be born to them. The following data will prove helpful in meeting this responsibility: Amyotonia congenita is familial. Multiple cases occur among siblings, but the disease is not hereditary; the disease may occur in one of double-ovum twins or in both of identical twins. It has been observed also in triplets, two of the triplets being identical and affected with the disease, the third being of separate ovular origin and unaffected.

Along with these important clinical observations stand the following pathologic anatomic data: Hypoplasia (retardation in development and maturation), not atrophy, of a large portion of the fibers in certain voluntary muscles is regularly present; malformation of the end plates of the motor nerves appears to have been satisfactorily demonstrated; hypoplasia of the spinal motor ganglion cells is a characteristic feature; heterotopia (malformation in migration) of the ganglion cells of the spinal cord occasionally has been observed; malformations of parts of the body other than the central nervous system are common.

Correlation of these data suggests very strongly that amyotonia congenita is the result either of defective development of the fertilized ovum or of an essential biologic deficiency in one or both of the gametes. Recorded observations provide no support for a maldevelopment of the central nervous system referable to any injury to an originally normal fertilized ovum. Likewise there are no critical data to support a pathogenic theory based on continued destruction of fully formed spinal ganglion cells during fetal development. Specifically against such a theory are the following observations: Significant gliosis of the spinal cord has not been observed; recorded instances of ganglion cell degeneration may be attributed to terminal secondary pathologic processes either in the mother or in the child; progressive myelin degeneration of the anterior spinal nerve roots has not been observed. The characteristic absence of myelin sheaths may be considered a failure of development of these structures; even in cases in which the disease progresses rapidly, no inflammatory reaction has been described in the central nervous system, in the muscles or in the peripheral nerves.

In the light of these and other less essential observations, in summary, the following statements seem justifiable:

1. Amyotonia congenita may be considered a focal retardation or cessation in the development of voluntary muscles resulting from a malformation of the central nervous system involving chiefly, if not exclusively, the peripheral motor neurons. This malformation occurs in intrauterine life, most likely before the sixth month of gestation.
2. The disease not infrequently occurs in siblings but does not occur necessarily in all children of a given family.
3. Amyotonia congenita being essentially a congenital malformation fully developed and most likely completed during intrauterine life, improvement in or elimination of the basic defect is not to be expected, even though the disease may be compatible with life for a number of years.

IMMUNOGENIC DIET

Important data on the relation of diet to natural resistance have been posthumously reported by Webster[1] of the Rockefeller Institute. Webster and his associate had available for this work five inbred strains of mice. Each strain had been reared under strictest quarantine conditions for at least ten years. They sought first the selection of a natural food that would best support the normal physiologic welfare of mice. Following suggestions of earlier investigators[2] they tested the nutritional properties of various whole grain cereals (66 per cent) in combination with 33 per cent whole dried milk and 1 per cent sodium chloride. The cereals tested were wheat, corn, rye, oats and rice, with desiccated potato tested as a control.

Inspection of the life cycle data of various groups of weanling Swiss mice revealed that, when growth, fertility, fecundity, ability to rear young and growth of those young were used as criteria, the most satisfactory overall diet was the whole wheat-dried milk-salt mixture. Corn and rye were next in order. Rice was less satisfactory, having especially poor ability to support the rearing of sucklings. Potato and oats were equally inadequate on several counts, notably in the extremely poor growth of the progeny. Infection tests performed when the progeny were 5 weeks of age showed that the potato and oats fed progeny were hypersusceptible to experimental Salmonella enteritidis infection. Progeny fed on the other grains were of approximately equal resistance. As a result of these tests the whole wheat-whole milk diet was selected as the "natural" dietary point of resistance.

Weanling Swiss mice were reared on this "natural" diet, with an equal number of controls reared on a synthetic diet containing all known food essentials in as pure a state as possible. This synthetic diet contained all known vitamins at levels well above minimal requirements. The "natural" and synthetic diets were approximately equal in supporting growth. Comparison of their effects on natural resistance were made by inoculating each mouse by means of a stomach tube with 50,000 S. enteritidis bacilli. Of 293 mice reared on the "natural" diet 194 survived this infection, a survival rate of 66.2 per cent. Of 296 mice on the synthetic diet there were only 120 survivors, a survival rate of but 40.5 per cent. The test was repeated with a tenfold dose of S. enteritidis (500,000 bacilli). The average survival rate for mice on the "natural" diet was 37.5 per cent. On the synthetic diet the survival rate was but 17.7 per cent.

In both series the natural resistance was maintained at a higher level on the whole wheat-dried milk diet than on the best synthetic diet now available. In a search for the factors involved in this superiority, groups of mice were fed various combinations of synthetic diet and "natural" foods. Inoculation tests showed that the greater natural resistance of mice subsisting on the "natural" food was due to the whole wheat it contained, dried milk contributing nothing to this immunogenic effect. The physical or chemical nature of the whole wheat immunogen is not yet determined.

Several by-products of this research are of suggestive clinical interest. First, it was found that the resistance of females is less than that of males on all diets thus far tested. Thus, with the average survival rate of 40.5 per cent on the synthetic diet, the male survival rate was 51.0 per cent and the female rate but 29.9 per cent. Differences were also noted in different inbred strains of mice. With strains of mice of high hereditary resistance the immunogenic effect of the whole wheat diet was less pronounced than with strains of low hereditary resistance.

Whether or not the whole wheat immunogen is equally effective against organisms other than S. enteritidis or with portals of entry other than the gastrointestinal tract has not yet been determined. The relative titers of different types or grades of wheat and the effects of cooking also have not yet been reported. Evidently, however, Webster introduced a new test for nutritional efficiency which may have important applications to future research in clinical medicine and animal husbandry.

Current Comment

CONGENITAL DEFECTS FOLLOWING MATERNAL RUBELLA

From 1937 to 1942 rubella was widely prevalent in Australia. Gregg[1] and others[2] have reported the occurrence of grave eye, ear, cardiac and other congenital defects in the children born during these years of mothers who had rubella during the early months of pregnancy. At present this appears to be the first time that such defects have been recorded in connection with rubella. The virologist Burnet writes[3] that the defects "may represent the development of a new capacity on the part of the virus, but more probably it is only a reflex of the unusual opportunity presented to the virus by the existence of a large young adult population susceptible to infection." The startling Australian reports were soon followed by reports of cases in this country of congenital defects following maternal rubella early in pregnancy.[4] Instances have been observed in England also.[5] While the strange power of rubella to cause congenital defects is not limited to Australia, the possibility cannot be excluded that the Australian virus may have been introduced into this and other countries. The production by Hiro and Tasaka[6] and by Habel[7] of rubella in monkeys on inoculation of blood and nasal washings from early stages of the human disease has established quite clearly that rubella is a virus infection. The virus can be cultivated on the chorioallantoic membrane of the chick embryo.[7] These results warrant further work now much needed in the hope it may lead not only to a better understanding of the genesis of congenital malformations in general but also to means of preventing the tragic effects of rubella in early pregnancy. The importance of rubella in this respect cannot be overstated. On the basis of the facts then at hand Swan[2] estimated that practically all children of mothers who have rubella in the first two months of pregnancy and 50 per cent of those having it in the third month will be defective. The frequency of malformation after rubella in pregnancy is a matter for careful investigations under different conditions. In Milwaukee Fox and Bortin[8] found that of five women who had rubella in the first two months of pregnancy only 1 gave birth to an abnormal child (stillborn and hydrocephalic). There can be no question that special efforts must be made to prevent rubella in early pregnancy. At this time all contacts with persons suffering from rubella must be avoided, especially by the woman who has not had the disease. Perhaps specific means of prevention will become available.

HEARINGS ON S. 1606 SCHEDULED

The Senate Committee on Education and Labor has scheduled hearings on S. 1606, the second 1945 version of the Wagner-Murray-Dingell bill, to commence on Monday, March 18, at 10 a. m. These hearings will last, it is reported, for about a month, and plans are being completed so that the Association will be adequately represented during the course of the hearings. Senator Murray, Montana, the co-sponsor of the bill, is chairman of the committee, and the other members, together with the states they represent, are as follows:

Senator George D. Aiken, Vermont
Senator Joseph H. Ball, Minnesota
Senator Dennis Chavez, New Mexico
Senator Forrest C. Donnell, Missouri
Senator Allen J. Ellender, Louisiana
Senator J. William Fulbright, Arkansas
Senator Joseph F. Guffey, Pennsylvania
Senator Lister Hill, Alabama
Senator Olin D. Johnston, South Carolina
Senator Robert M. LaFollette Jr., Wisconsin
Senator Wayne Morse, Oregon
Senator Claude Pepper, Florida
Senator H. Alexander Smith, New Jersey
Senator Robert A. Taft, Ohio
Senator Elbert D. Thomas, Utah
Senator James M. Tunnell, Delaware
Senator David I. Walsh, Massachusetts

The House Committee on Ways and Means began public hearings on the subject of social security on February 25. The first 1945 version of the Wagner-Murray-Dingell bill is still pending before this committee and may be considered during the course of these hearings. Present indications are, however, that the initial hearings will be on the old age and survivors' insurance provisions of the Social Security Act and thereafter will extend progressively to other phases of the act, such as old age assistance, aid to dependent children, aid to the blind, general assistance and unemployment compensation. These hearings will consider the report of the committee's social security technical staff, recently submitted to the committee under the title "Issues in Social Security," which does not cover the problem of medical care in its broad application but does refer to the need of providing medical care to the recipients of public assistance, the aged, the dependent children and the blind.

TEMPORARY APPROVAL OF RESIDENCIES

Many hospitals are rapidly developing new educational programs at the residency level to meet the needs of returning medical officers who are seeking such work in large numbers. It has been deemed wise by the Council on Medical Education and Hospitals of the American Medical Association and by the executive committee of the Advisory Board for Medical Specialties to inaugurate a plan to facilitate at least temporary approval of new residencies. The plan proposed by these bodies is described elsewhere in this issue. This program should contribute materially to meeting the educational demands during this acute emergency. Temporary approval of a hospital in the manner described will protect such residents as may be enrolled in the educational program of the hospital so far as credit toward specialty board certification is concerned. Every effort will be made by representatives of the Council and the boards to be reasonably sure that subsequent inspection of the residency will reveal that the program warrants regular approval. The judgment of the Council and of the boards will be based on a careful study of the personnel, hospital statistics and educational program outlined by the hospital on making application for approval to the Council. The proposal has met with approval by a number of the boards. Most of them have already indicated that they will collaborate in this project. It is probable that most, if not all, of the remaining American boards will likewise participate.

HYPERSENSITIVITY RHEUMATIC FEVER

One concept of the etiology of rheumatic fever involves hypersensitivity. Aikawa[1] has recently reviewed the evidence in favor of this hypothesis. He points out that the nature of the antigen-antibody reaction has been firmly established on an experimental biochemical basis. The question of the relationship between immunity and allergy remains unsolved, however. Attempts to treat rheumatic fever on the basis of the desensitization theory have so far yielded equivocal results. The hypersensitivity theory of the causation of the rheumatic fever and the rationale of attempted desensitization may or may not be confirmed by subsequent investigations. In any event Aikawa deserves credit for his careful review of the evidence on this subject to date.

CONTINUATION COURSES

Elsewhere in this issue the Council on Medical Education and Hospitals of the American Medical Association presents a supplementary list of continuation courses. On Dec. 8, 1945 The Journal contained a long list of such courses being offered throughout the country for the period Jan. 1 to July 16, 1946. Because of the heavy demands for such work, many institutions have accelerated their plans for short courses and have reported considerable numbers of them since January. Further supplementary lists will be published as the need arises before the regular semiannual compilation, which will appear early in July.

MEDICINE AND THE WAR

NAVY

TRAINING IN AVIATION MEDICINE

The Bureau of Medicine and Surgery, Navy Department, Washington, D. C., recently made an urgent request for application for training in aviation medicine. This training leads to the designation of Naval Flight Surgeon, and eligibility is limited to medical officers of the rank of lieutenant commander or below.

The School of Aviation Medicine is conducted at the Naval Air Station, Pensacola, Fla. Classes are formed on an average of every four months, one having started in February. Two months' instruction is offered in applied aviation physiology, eye, ear, nose and throat, psychiatry and certain other subjects. Students are then assigned to flight indoctrinational training and ground school work for six weeks. On completion of the training program the student is designated as naval flight surgeon and receives his wings.

VOLUNTEERS TO BE TRAINED IN MEDICAL STATISTICS

The Bureau of Medicine and Surgery, Washington, D. C., recently issued a call for volunteers to be trained in the specialty of medical statistics. Capt. Fred R. Lang, chief of the Division of Statistics, has arranged for instruction of interested medical officers at the School of Hygiene and Public Health, Johns Hopkins University, Baltimore.

Unless a heavy registration necessitates an earlier, more concentrated course, the training program in medical statistics will begin on September 1. All interested medical officers of the Regular Navy are urged to send in their applications to the chief of the Bureau of Medicine and Surgery at the earliest possible date.

COMMODORE JOHN C. ADAMS PRESENTED THE JOHN JEFFRIES AWARD

The John Jeffries Award was recently presented to Commodore John C. Adams, New York, "for outstanding contributions to the advancement of aeronautics through medical research." Commodore Adams graduated from the University of Alabama School of Medicine, University, in 1917 and was appointed Lieutenant (jg), Medical Corps of the U. S. Navy, in 1917. He completed training as a flight surgeon at the Army School of Aviation Medicine in 1923, and since that time his interests have been primarily confined to aviation medicine.

NAVY AWARDS AND COMMENDATIONS

Rear Admiral William John Clarke Agnew

Rear Admiral William J. C. Agnew, assistant chief of the Bureau of Medicine and Survey, Navy Department, was recently awarded the Legion of Merit "for exceptionally meritorious conduct in the performance of outstanding services to the government of the United States as director of personnel, including the Medical Corps, Hospital Corps and Nurse Corps, from the beginning of the emergency to Nov. 24, 1944 and as assistant chief of the bureau from Nov. 25, 1944 to the surrender of the Japanese empire." According to the citation accompanying the award "by his dynamic leadership and his competence in handling problems of the greatest complexity during a period when the demand for medical officers and nurses was rising steadily, Rear Admiral Agnew was able to coordinate the recruiting and training of medical personnel in departmental duties, thereby insuring expeditious assignment to ships, advance bases and hospitals throughout the world as well as to the shore stations and hospitals at home. Serving as assistant chief of the bureau, he bore the entire responsibility for the operation of the Medical Department of the Navy during the absence of the Surgeon General and, by his quick grasp of essentials, his inherent ability to make immediate and correct decisions and his calm performance of duty under stress, contributed vitally to the successful operation of the Medical Department." Dr. Agnew graduated from the University of Vermont College of Medicine, Burlington, in 1914 and entered the service June 2, 1917.

Commander Julius M. Amberson

The Distinguished Service Medal was recently awarded to Comdr. Julius M. Amberson, formerly of Corpus Christi, Texas, "for exceptionally meritorious service to the government of the United States in a duty of great responsibility as medical officer in command of Epidemiology Unit No. 50, operating in Egypt, Lebanon, Turkey and East and South Africa over an extended period of time." The citation accompanying the award stated that, "obtaining protocols to establish the official presence of his unit in the East, Middle East and Africa, Commander Amberson conducted pioneer research in the treatment of Asiatic cholera and relapsing fever, developing the unit into a potent force in the control of endemic diseases, a source of sound basic research and creator of good will toward the United States. He maintained effective liaison with the United States Typhus Commission stationed in Egypt and later assumed responsibility for the commission's duties, equipment and continuing clinical investigations. In addition, he demonstrated the value of penicillin in treating the victims of relapsing fever. Introducing a revolutionary cure for Asiatic cholera after extensive and painstaking scientific and medical development, Commander Amberson applied this treatment in 500 cases of this ordinarily fatal disease and, by his efforts, prevented the loss of a single life in the test group, thereby bringing to mankind a new method of treatment which will undoubtedly save the lives of untold thousands in the years to come. Through his professional skill, administrative ability and great scientific motives maintained despite his continual exposure to fatal endemic diseases, Commander Amberson has made an outstanding contribution in the field of medical research, and his unwavering devotion to an important assignment reflects the highest credit on himself and the United States Naval Service." Dr. Amberson graduated from Rush Medical College, Chicago, in 1927 and entered the service Sept. 24, 1942.

Captain Don S. Knowlton

A gold star in lieu of a second Legion of Merit was recently awarded to Capt. Don S. Knowlton, Washington, D. C., for exceptionally meritorious conduct in the performance of outstanding services as division surgeon of a Marine infantry division during the planning for and conduct of operations against the Japanese enemy on Okinawa, Shima, Ryukyu Islands during the period from April 1 to June 21, 1945. "During the preparatory phase of the operation," stated the citation, "Captain Knowlton, with untiring efforts, supervised the organization and training of the medical battalion within the division. With keen technical skill and professional ability he trained his command to a high state of readiness for amphibious operations. During the assault phase of the operation the medical companies under his direction kept constantly in contact with the advancing front lines troops, offering prompt and efficient medical aid and surgical treatment to those wounded or injured in action. The ability of the individual corpsmen, the capabilities of the unit medical officers, the efficiency of the medical organization, the promptness of the evacuation of wounded, all attested to his brilliant leadership. Throughout the entire operation he demonstrated an extremely high degree of professional knowledge both as a member of the medical profession and as a naval officer. He kept constantly in touch with the rapidly changing tactical situation so that he might better employ the men of his command. His sound judgment, both tactically and medically, his inspiring leadership and his intense devotion to duty were ever an inspiration to the men of the division and aided materially in the furtherance of the operation. His actions throughout were in keeping with the highest traditions of the United States Naval Service." Dr. Knowlton graduated from Tufts College Medical School, Boston, in 1921 and entered the service Nov. 5, 1940.

Captain Theodore R. Meyer

The Cross of the Order of Taxiarchis was recently awarded to Capt. Theodore R. Meyer, Sag Harbor, L. I., N. Y., for services rendered to the population of Greece. Captain Meyer recently returned from Greece after ten months' duty as officer in charge of a special Navy epidemiologic unit formed at the request of the Greek government for the purpose of improving public health conditions in that formerly enemy occupied country. The unit that Captain Meyer headed, comprising four officers and ten hospital corpsmen, worked in close cooperation with the Greek Ministry of Health. Education of native physicians and technicians in the uses and administration of penicillin was undertaken. The epidemiologic unit established a school for instruction in laboratory procedures, conducted surveys of sanitary conditions in restaurants and other food handling establishments in the Athens-Piraeus area, instituted malaria control measures on small islands off the coast of Greece and furnished assistance, including the loan of equipment and materials, to the government's hygiene school. Dr. Meyer graduated from the Medical College of the State of South Carolina in 1924 and entered the service April 1, 1941.

With the generous cooperation of certain American citizens of Greek descent, Captain Meyer's unit has arranged for two Greek doctors to come to the United States for specialized study at the National Navy Medical Center, Bethesda, Md.

Lieutenant Commander Francis X. Sommer

Lieut. Comdr. Francis X. Sommer, formerly of Ashburnham, Mass., was recently commended "for distinguishing himself by excellent service as medical officer for the Commander Manila-Subic Harbor Clearance Group. On Aug. 11, 1945 a U. S. Army diver, having completed a dive in Mariveles Harbor, Luzon, Philippine Islands, experienced a severe case of bends. Lieutenant Commander Sommer diagnosed the critical condition of the man, used improvised equipment from enemy stores and then worked continuously for a period of more than two days until the patient was restored to health. For his outstanding performance of his duties he is commended and authorized to wear the Commendation Ribbon." Dr. Sommer graduated from Yale University School of Medicine in 1940 and entered the service July 1, 1941.

Commander Maksymiljan Robert Gelber

Comdr. Maksymiljan Robert Gelber, Aberdeen, S. D., was recently commended "for distinguishing himself by excellent service as senior medical officer of the Escort Carrier U. S. S. *Hoggatt Bay* during operations against the enemy in the Luzon (Manila-Lingayen) campaign, Philippine Islands, Jan. 1-23, 1945. During this entire period, by his skill and devotion to duty the general health of the crew was maintained at a remarkably high level. When a deck explosion occurred, Commander Gelber's department was so well organized that they not only handled the casualties in an outstandingly efficient manner but also effected a plan to lower stretcher cases to sick bay. For his conduct throughout he is commended and authorized to wear the Commendation Ribbon." Dr. Gelber graduated from the University of Minnesota Medical School, Minneapolis, in 1926 and entered the service May 15, 1941.

MISCELLANEOUS

AMERICA TYPHUS COMMISSION AWARDS

Dr. William W. Bolton

On February 13 Dr. William W. Bolton, assistant director of the Bureau of Health Education of the American Medical Association, Chicago, was presented with the United States of America Typhus Commission Medal in recognition of noteworthy service rendered in the control of typhus in Germany during the period March 6, 1945 to June 14, 1945. The presentation was made by Brig. Gen. John A. Rogers, U. S. Army, chief surgeon, Sixth Service Command. Dr. Bolton, who graduated at Jefferson Medical College in 1930, entered the Army of the United States July 1, 1945. His service terminated Jan. 13, 1946 with the rank of captain. While in Germany Dr. Bolton was in charge of a typhus team that was responsible for locating and isolating all persons with the disease.

Dr. Leonard A. Scheele

Dr. Leonard A. Scheele, senior surgeon, U. S. Public Health Service, was recently awarded the United States of America Typhus Commission medal for "exceptionally meritorious service" which helped prevent the spread of typhus in northwestern Europe during 1944-1945. Dr. Scheele served in the Mediterranean and European theaters of operation from May 1943 to September 1945 while on temporary duty with the Army Medical Department. As chief of the preventive medicine section, Public Health Branch, he took an important part in the development of policies, the determination of principles and the accumulation of supplies essential for typhus control among refugees and displaced persons in Germany and in allied countries of northwestern Europe. On his return from Europe Dr. Scheele resumed his activities with the Public Health Service and is now assistant chief of the National Cancer Institute at Bethesda. He was a consultant on cancer control at the institute for a number of years prior to his first wartime assignment in December 1942, which placed him with the Office of Civilian Defense as deputy for field medical operations.

Dr. Scheele joined the regular corps of the Public Health Service in July 1934. He graduated from Wayne University College of Medicine, Detroit, in 1934.

MEDICAL AND SURGICAL RELIEF COMMITTEE

The Medical and Surgical Relief Committee (420 Lexington Avenue, New York 17) in its annual report for 1945 announced through Mr. George L. Knoll, chief of procurement and distribution, that pharmaceutical supplies contributed during the year amounted to $29,859.99. The Medical and Surgical Relief Committee donates medical, surgical and dental supplies to meet authentic appeals from hospitals, missions and welfare organizations in all parts of the world. The fine cooperation of supply houses has enabled the committee to send otherwise unobtainable supplies to Italy, Greece, Africa, France, Korea, Czechoslovakia, the Netherlands, China, Nicaragua, Bolivia and Central America during the past year. In most of these areas doctors and dentists have been helpless to combat disease because of the complete lack of equipment. The Medical and Surgical Relief Committee meets emergencies of this kind by sending quickly enough basic material and instruments to permit clinical routine to be reestablished. Only those organizations which supply free service to patients are assisted.

UNRRA NEWS

Yugoslav Doctor to Study Latest Serum Technics in London

The United States Relief and Rehabilitation Administration, Washington, D. C., recently sent Dr. Mirke Stanic, Yugoslav serologist, to London to study the latest serology methods, according to a Belgrade report to the Washington headquarters of UNRRA.

The fullest use is now being made in Yugoslavia of UNRRA-supplied penicillin. At a recent meeting of the Yugoslav Federal Penicillin Center and the Belgrade Medical Society, special mention was made of the success of penicillin treatment in Yugoslavia and of the invaluable assistance given the country by the Health Division of the UNRRA Mission there.

Steps to forestall the introduction of bubonic plague also are being taken by the Sanitary Engineering Section of the UNRRA Mission, and preventive measures are being concentrated at ports on the Dalmatian coast.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

Feb. 25, 1946.

Contract Hospitalization for Veterans Criticized by Legion

The Veterans Administration's contract hospitalization program is under fire from the American Legion. Commander John Stelle, who is reported to be coming to Washington to "bury the hatchet" in his squabble with Veterans Administrator Omar Bradley, has called for facts and figures from every state on contract hospitalization. Veterans claim it was not satisfactory after the last war, and Mr. Stelle says it will "be pretty tough on these new veterans." The veterans agency, in what is planned as a nationwide project, has already arranged with four state hospital associations to contract with private institutions to furnish beds for veterans with service connected ailments. The Legion chief plans to present information to General Bradley and the veterans' medical director, Major Gen. Paul R. Hawley. General Bradley says his agency has already asked for seventeen surplus army and navy hospitals, bub the Legion feels that more should be used for veterans. General Hawley contends that only where there are plenty of good doctors available will hospitals be taken over. "It is the worst kind of fraud to offer the veteran a hospital in which it is impossible to give him first class medical care." General Bradley reports a reluctance by employers to hire disabled veterans.

Wallace Starts Controversy in Des Moines Speech

The charge by Commerce Secretary Wallace in his recent Des Moines speech that western pigs are better nourished than Washington, D. C., school children stirred up a lively controversy. Mr. Wallace claimed that he usually saw ill fed, undernourished children on his home to office walks each day. Dr. Thorval L. Hickman, Gallinger Hospital pediatrician, called the secretary's remarks "exaggerated" and pointed out that standards for determining proper nourishment vary. Dr. Roland B. Scott, pediatrics chief at Freedman's Hospital, reported that 95 per cent of the children brought to that hospital suffered from malnutrition.

Women to Get Role in Postwar Army

The War Department will seek early legislation establishing the Army Nurse Corps, the proposed Women's Medical Specialist Corps and the Women's Army Corps in the postwar military establishment, according to Major Gen. Willard S. Paul, assistant chief of staff. He addressed a conference of delegates of leading women's groups at the Pentagon Building. General Paul said that as the bill is now being drawn the Army Nurse Corps will be made a permanent corps in the Regular Army and it will give reserve status on request to nurses who served honorably during World War II. The legislation would also include a Women's Medical Specialist Corps consisting of women in the present Dietitians and Physical Therapists Corps. Reserve status will also be sought for discharged Wacs and would include the wartime corps in the permanent army.

School Lunch Program Bill Approved by House

The House of Representatives has passed by a 275 to 101 vote, and sent to the Senate, the bill authorizing the federal government to spend $50,000,000 on state school lunch programs. Also passed was an amendment by Representative Powell, Democrat of New York, prohibiting funds to states or schools in which students are discriminated against because of race or color.

Capital News in Brief

Brig. Gen. George R. Callender, U. S. Army, assistant commandant of the Medical Department Professional Service Schools, presented awards to civilian employees of the Army Medical Service who were honored for meritorious service.

Temporary relaxation of Washington zoning regulations has been asked to permit doctors unable to get office space to use their living quarters for offices.

Congress has been urged to bypass the controversy between public and private housing on how to clear Washington, D. C., slums and to approve a $20,000,000 Redevelopment Agency in Washington.

Open hearings on legislation to ban experimentation on dogs in the District of Columbia have been set for 10 a. m. Thursday, February 28.

The District of Columbia Medical Society, which took an important part through its delegates in working out the American Medical Association health insurance program, will launch the program here shortly, it is reported.

Group Health, Inc., medical cooperative of government workers, voted at its annual meeting here to extend its medical service "without racial discrimination."

Persons who paid large medical and dental bills in 1945 are advised to make their 1945 income tax returns on the long form 1040 to save money.

Official Notes

TEMPORARY APPROVAL OF RESIDENCIES

Because of the large number of applications for approval of residency training programs submitted by hospitals developing these programs in response to the increased demand for training by returning medical officers, the Council on Medical Education and Hospitals of the American Medical Association has approved a plan for the temporary approval of residencies. This plan was developed in collaboration with the Advisory Board for Medical Specialties through its executive committee. A majority of the American boards in the specialties has already indicated an approval of the proposal. It is anticipated that other boards, if not all of them, will subscribe to the plan. The program is as follows:

1. The Council on Medical Education and Hospitals of the American Medical Association has temporarily delegated to its secretary the authority to grant temporary residency approval on behalf of the Council subject to concurrence by the appropriate American board as described in No. 2.

2. Each participating American board has appointed representatives (usually one individual for each board) to consider new residencies for temporary approval with authority to act on behalf of the board.

3. Temporary approval will be based on information from the hospital concerning the personnel, facilities and educational program of the hospital service involved without immediate inspection. Such approval will be granted only if the representatives of the Council and of the board are reasonably satisfied that the educational program fulfils the standards of both bodies.

4. Subsequently, employing the usual procedures, an inspection of the hospital will be carried out by the Council's staff. On the basis of inspection report, the Council will consider the temporarily approved hospital for transfer to the regularly approved list in the usual manner. The inspection report and the recommendations of the Council will be submitted to the appropriate board, and the board will return its concurrence or disagreement with the Council. The result of this procedure would be either (*a*) transfer of the temporarily approved residency to a fully approved status or (*b*) withdrawal of the temporary approval.

5. In the event of withdrawal of temporary approval and failure to grant regular approval, credit toward board certification will be given to physicians for that part of their training received while the residency was on a temporary approval status. After such withdrawal of approval, residents seeking board certification will be given a reasonable time to obtain another acceptable residency without loss of time credit. This means that no resident would be penalized so far as board credit is concerned for time spent in a temporarily approved residency.

In seeking approval by the Council on Medical Education and Hospitals, those hospitals which organize new residencies should initially make no distinction between regular versus temporary approval. Applications should be transmitted to the Council in the regular manner. In the immediate future most, if not all, applications will be considered at once for temporary approval. The Council's staff will proceed with regular inspections as rapidly as possible so that transfer of acceptable hospital residencies from the temporarily approved to the regular approved list will take place as rapidly as possible if the inspection report seems to warrant such transfer in the opinion of the representatives of the Council and of the American board concerned.

DOCTORS AT HOME BROADCASTS

The American Medical Association in cooperation with the National Broadcasting Company broadcasts each Saturday afternoon at 4 o'clock eastern standard time (3 p. m. central standard time, 2 p. m. mountain standard time, 1 p. m. Pacific standard time) under the title "Doctors at Home." This is the sixth season of broadcasting in dramatized form under the general title "Doctors at Work." The broadcasts present a serial story of the experiences of a fictitious doctor just returned from service as a medical officer of the United States Army.

The next three programs are as follows:

March 2. Surgery Saves Blue Babies; the story of arterial surgery.
March 9. The Tale of a Gland; about toxic goiter.
March 16. Dogs, Cats and Squirrels; the story of rabies.

The programs are summarized by Drs. W. W. Bauer and William W. Bolton of the Bureau of Health Education.

Announcement folders have been prepared for distribution locally. These may be had in quantities of 100 by applying to the Bureau of Health Education. Local distribution can be made effectively by the Woman's Auxiliary groups.

Council on Medical Service and Public Relations

REGIONAL CONFERENCE OF REPRESENTATIVES OF MIDDLE ATLANTIC STATES

At the request of the Council on Medical Service and Public Relations of the American Medical Association a regional conference of the representatives of the Middle Atlantic states, including New York, New Jersey, Delaware, Pennsylvania, District of Columbia, Virginia and Maryland, was held at Philadelphia on Thursday, January 31. More than fifty representatives attended.

The conference took the form of an all day round table discussion highlighted particularly by steps toward the formation of a permanent regional organization. It was stressed that this organization should function in a two way manner in order to bring to this area both the desires and information from the national council and convey more in detail the problems and progress made in the several states included in the conference. The following committee was appointed to effect this organization: Dr. F. F. Borzell, Pennsylvania, chairman; Dr. J. M. Emmett, Virginia; Dr. F. J. Quigley, New Jersey; Dr. H. H. Bauckus, New York, and Dr. L. R. Wharton, Maryland; representatives from the District of Columbia and from the Delaware State Medical Society are to be named later.

The conference discussed in detail plans already in operation covering both prepaid medical care to all groups and the cooperation of the several states in the reorganized Veterans Administration program. The latter subject was presented effectively by Col. J. C. Harding, acting director, outpatient service, Veterans Administration, officially representing General Hawley, medical director. From each state represented a frank, factual report was given on the status of medical care problems in that state.

It was obvious that the greatest need at the present time is more effective participation of the county medical societies. Public relations activities were stressed, and here again the necessity for stimulation of local public relations activities through county medical societies is imperative. Said Dr. Borzell, the chairman, "While this was the first conference in this area, it was quite obvious that, as indicated by the active participation of those present, regional conferences have a place in carrying forward both the defensive fight against federal control of medicine as well as the positive constructive program of meeting obvious medical care needs." Another conference of this region will be held early in May.

Those who took part in the program were Dr. F. F. Borzell, chairman, Council on Medical Service and Public Relations, Medical Society of the State of Pennsylvania; Dr. William L. Estes Jr., president, Medical Society of the State of Pennsylvania; Mr. Jay Ketchum, executive vice president, Michigan Medical Service Association, and chairman of the Advisory Committee on Prepayment Medical Care of the Council on Medical Service and Public Relations; Mr. Thomas A. Hendricks, secretary, Council on Medical Service and Public Relations; Col. J. C. Harding, M. C., acting director, outpatient service; Dr. Norman M. Scott, medical director, Medical Service Administration of New Jersey, and executive assistant, Medical Society of New Jersey; Dr. Walter F. Donaldson, secretary-treasurer of the Medical Society of the State of Pennsylvania; Mr. Roy Jansen, publicity representative, Medical Society of the State of Pennsylvania; Mr. James E. Bryan, executive secretary, New York County Medical Society; Mr. Theodore Wiprud, executive secretary, Medical Society of the District of Columbia, and Dr. Joseph S. Lawrence, director of the Washington Office of the Council on Medical Service and Public Relations.

ATTITUDE OF CHICAGO WOMEN TOWARD MEDICINE

Chicago women are not in favor of socialized medicine, a survey conducted January 28 in the city's Loop area by the Chicago *Tribune* indicated. Of the first fifty women interviewed at the corner of State and Washington streets by *Tribune* writer Norma Lee Browning, only one said that she was willing to relinquish her freedom of choice of a physician or that she wanted free hospitalization and medical care at the expense of an increase in taxes. That one was a native-born German.

The survey was prompted by a doctor's statement that women in general are more doctor conscious than men and should be concerned over what the Wagner-Murray-Dingell proposal for a government medical plan would mean to them and to their families.

Few of the women interviewed, said the *Tribune* reporter, knew anything about the Wagner-Murray-Dingell bill. Most of them admitted that they didn't understand socialized medicine but expressed a fear that in some way it would trespass on sacred territory.

PREPAID MEDICAL CARE NEWS

American Pharmaceutical Association Appoints Committee to Study Medical Care

The Council of the American Pharmaceutical Association and the Executive Committee of the N. A. R. D. at their joint meeting in 1944 suggested the appointment of a joint committee of the two associations to study and supply information on various plans that may be suggested for prepaid medical care, with special reference to the pharmaceutical phases of such plans.

The members of the committee elected Dr. Robert P. Fischelis, secretary of the American Pharmaceutical Association, as chairman. The committee is now in the process of obtaining information from medical societies, pharmaceutical associations and state boards of health on various available plans, preparatory to studying these plans.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Scientific Research

A revised bill, S. 1850, has been introduced proposing to promote the progress of science and the useful arts, to secure the national defense and to advance the national health and welfare. This bill was introduced by Senator Kilgore, West Virginia, for himself and Senator Magnuson, Washington, Senator Johnson, Colorado, Senator Pepper, Florida, Senator Fulbright, Arkansas, Senator Saltonstall, Massachusetts, Senator Thomas, Utah, and Senator Ferguson, Michigan. This legislation would create a National Science Foundation administered by an administrator to be appointed by the President after consultation with the National Science Board to be created by the law.

School Lunch Programs

The House has passed H. R. 3370, to authorize the federal government to contribute $50,000,000 a year to school lunch programs. This federal fund will be matched 50-50 by participating states beginning July 1, but the bill requires that the federal government would spend $1 for each $2 expended by the states in 1948, $1 to $3 in 1949 and 1950, and $1 to $4 thereafter.

Hearings

The Senate Committee on Education and Labor has scheduled hearings on S. 1606, the second 1945 version of the Wagner-Murray-Dingell bill, to begin March 18.

The House Committee on Ways and Means began hearings on social security legislation, February 25.

The House Committee on the District of Columbia has scheduled hearings on the Lemke antivivisection bill, H. R. 491, to begin February 28.

STATE LEGISLATION

California

Bills Passed.—A. 88-X passed the senate February 12. It proposes the creation of a State Advisory Council on Hospital Facilities and would authorize the Department of Public Health to make a survey of existing public and private hospitals and health centers in the state, to evaluate the sufficiency of such hospitals and health centers to supply the necessary physical facilities for furnishing adequate hospital, clinic and similar services to the people of the state, and to make any recommendations concerning additional facilities as may be necessary. S. C. R. 16-X passed the house February 15. It proposes a resolution requesting the state director of finance to appropriate $44,000 for the purpose of carrying out a 1945 law providing for the better protection of the public health by state licensing, inspecting, regulating and supervising of public and private hospitals.

Bills Enacted.—A. 35-X has become chapter 33 of the Laws of 1946. It authorizes the appropriation to the Regents of the University of California of the sum of seven million dollars for the purpose of establishing, equipping and maintaining a medical school and center as a unit in the University of California at Los Angeles. A. 37-X has become chapter 31 of the Laws of 1946. It amends the Business and Professions Code so as to increase the annual tax and registration fee of osteopaths from $5 to $10 for residents and from $2 to $10 for nonresidents. S. J. R. 7-X was filed with the secretary of state, February 11. It requires that the President of the United States and the Veterans Administration be memorialized to enter immediately into contracts with the Army and Navy to take over an adequate number of hospitals in California adequately staffed to furnish hospital facilities for veterans.

Kentucky

Bills Introduced.—H. 347 proposes regulations for the licensing of manufacturers, wholesalers, jobbers and retailers of foods and drugs. S. 152, to amend the law relating to the practice of pharmacy, proposes that any one who, while in the service of the armed forces, was regularly employed for a period of not less than twelve months in the preparation and dispensing of drugs and medicines and who, in addition thereto, has successfully completed at least two years of study in a recognized college of pharmacy may apply for a pharmacist's license.

Bills Passed.—H. 257 passed the house February 18. To amend the law relating to divorce, it proposes to authorize the granting of a divorce when one spouse has become permanently and incurably insane and has been confined in an asylum for at least five years prior to filing the suit. In such action the court shall find from the testimony of two or more physicians competent in psychiatry that such insanity is permanently incurable. S. 109 passed the senate February 14. To amend the law relating to the practic of chiropractic, it increases the required period of academic training and adds philosophy to the list of subjects which must be studied.

Massachusetts

Bills Introduced.—H. 951, to amend the law relating to medical examinatons of injured persons in connection with accident cases, proposes that, if a person injured in an accident unreasonably refuses to submit to a medical examination to be made in the presence of his physician after a written request therefor is made by or on behalf of any person from whom damages have been claimed, such refusal shall be admissible in evidence and a proper subject for comment at the trial of any action brought to recover damages for bodily injuries or death resulting from such accident. S. 407 proposes the revocation of the charter of the College of Physicians and Surgeons.

Bill Enacted.—H. 1468 has become chapter 33 of the Laws of 1946. It amends the law relating to the restraint of patients in mental hospitals and provides that "restraints" shall not include chemical or mechanical restraint in cases of contagious disease, during the administration of anesthesia or following an operation or accident which has caused serious bodily injury, or during the administration of shock therapy, insulin treatment or any other recognized specific therapy.

New Jersey

Bills Introduced.—A. C. R. 3 proposes the enactment of an unemployment sickness compensation law. A. 91 proposes the creation of a board of chiropractic examiners to examine, regulate, license and register persons desiring to practice chiropractic. Chiropractic is defined to be "the philosophy, art, science and practice of things natural; a system of adjusting the articulations of the spinal column and adjacent tissues by hand only for the correction of the cause of disease." Licentiates would have the right "to practice chiropractic within this state and to that end shall have authority to examine patients and to diagnose and adjust for any interference with the transmission of nerve energy and to prescribe or regulate the patient's dietary, sanitary and hygienic requirements; also to use the Neurocalometer, x-ray and any other instrument for the purpose of diagnosis or analysis only, and such licensee shall have the right to employ nurses and assistants." The proposal would also declare chiropractic not to be a limited branch of medicine and surgery and would authorize a licentiate to use the title "Doctor" in connection with his name when accompanied by the name chiropractor or D.C. A. 171 proposes the creation of a Bureau of Cancer Control under the supervision of a director who shall be a duly licensed medical physician in the state qualified by training and experience to direct the work of cancer control and competent to administer cancer clinics. The bureau shall establish four cancer clinics within the state, each one under the direction of a duly licensed medical physician. A. 178, to amend the law relating to institutions designed for the care of communicable diseases, proposes to omit from the existing law the requirement that the superintendent of any such institution be a reputable, licensed and qualified physician of the state of at least five years' experience.

New York

Bills Introduced.—A. Res. 68 proposes the creation of a joint legislative committee to make a survey and study of the social, educational and physical problems of individuals afflicted with cerebral palsy, with special attention to those whose muscle involvement is commonly referred to as (1) spasticity or (2) athetosis or (3) ataxia and including those who have similar central motor or sensory defects. A. Res. 70 proposes the appointment of a joint legislative committee to make a study and investigation "of the discriminatory practices being carried on by the American College of Surgeons" with reference to barring "Negro surgeons from fellowship therein" A 1117 and S 1033 propose a new law relating to the licensing and regulating of the practice of barbering Barbering is defined as the performance of certain practices, among which are the giving of facial or scalp massages with oils, creams, lotions or other preparations, either by hand or mechanical appliances to males only and another is the applying of cosmetic preparations, antiseptics, powders, oils, clays or lotions to scalp, face or neck of males only Specifically exempted from the provisions of this proposal are duly licensed physicians, osteopaths, dentists, optometrists, nurses or physiotherapists, and hairdressers or cosmetologists A 1145 and S 986 propose the creation of a temporary state commission to examine into the need for and to make recommendations relative to the creation of a state university A 1167, to amend the law relating to hypnotic and somnifacient drugs, would prohibit prescriptions therefor from being refilled if the prescription bears a direction to that effect The proposal would further authorize the prescriber to indicate the number of times a prescription may be refilled If the prescription is silent as to the refilling, then the prescription may be refilled by the pharmacist during a period of not more than six months from the original date of the prescription A 1170 is the same as S 620 previously reported To amend the law relating to action for damages for death caused by wrongful act and the distribution of the proceeds thereof, it proposes to put in the first priority of items to be paid for when damages are distributed the reasonable expenses of medical aid, nursing and attention incident to the injury causing death A 1179 and S 975, to amend the workmen's compensation law, propose to authorize injured claimants to have free choice of hospitals for the treatment of injuries A 1200 and S 958, to amend the education law, propose the establishment of a New York state university with, among other subjects, a school of medicine A 1204 and S 1000, to amend the law relating to privileged communications, propose the waiver of such privilege by any party in interest in any litigation wherein the interests of the personal representative of the deceased patient are deemed by the trial judge to be adverse to those of the estate A 1223 and S 956 propose the enactment of a new law providing for the examination, licensing and regulation of persons desiring to practice hairdressing and cosmetology To engage in the practice of hairdressing and cosmetology means a person who "holds himself out directly or indirectly as being able, or who offers or undertakes, by any means or method, with the aid of the hands or of mechanical, electrical or other apparatus or appliances and/or by the use of tonics, lotions, creams, cosmetics, cosmetic preparations or compounds, to wave, dye, color, bleach cut, arrange, dress, curl, cleanse, or stimulate the growth of the hair of the head of a female person or to massage, cleanse or exercise the scalp, face, neck or arms, or manicure the nails, of such person, or to do any similar work intended to enhance the appearance of such person" Specifically exempted from the provisions of this proposal are duly licensed physicians, osteopaths, dentists, optometrists, nurses or physiotherapists and barbers A 1249 and S 1099, to amend the law relating to the practice of osteopathy, propose that persons holding a license to practice osteopathy who have been granted the additional rights provided for under existing statutes and persons who shall meet all the preliminary and professional requirements required as of Sept 1, 1936 and have satisfactorily passed or shall satisfactorily pass the regular medical licensing examination shall be granted the right to practice medicine without limitation as defined by the statutes of the state of New York A 1325 and S 1149 propose the creation of a temporary commission to make a comprehensive study and analysis of the care and treatment of patients in the mental hospitals of the state who are children under 16, seniles, arteriosclerotics, alcoholics and psychopaths, and to devise and recommend ways and means of improving the care and treatment of such patients A 1356 and S 1189, to amend the law relating to live pathogenic micro organisms or viruses, propose that persons cultivating or possessing live pathogenic microorganisms or viruses must satisfy the commissioner of health that such organisms or viruses will not become a menace to the public health and shall register with the commissioner of health The registration must be renewed each year A 1442 and S 1186, to amend the workmen's compensation law, propose that no claim for services by an x-ray laboratory or other laboratory shall be valid or enforceable unless such laboratory has obtained a license from the industrial commissioner This proposal would not apply to an authorized and qualified physician doing his own x-ray work in connection with his own treatment of injured workmen S 1045, to amend the workmen's compensation law, proposes to authorize an injured employee to have free choice of a dentist when dental care and treatment are necessary S 1085 proposes a licensing law for persons desiring to perform scientific experiments and vivisection on living dogs These licensing provisions would not apply to any laboratory, experimental or scientific activity conducted by the state of New York or to any agency of the federal government operating in the state of New York but every agency of the state or federal government operating in New York State, conducting scientific experiments or vivisection on living dogs, shall register with the department on a special form to be prescribed by the commissioner, without the payment of any license fee The fee would be one thousand dollars and would be renewed annually S 1173, to amend the education law, proposes to require the licensing of dental laboratories S 1354, to amend the law relating to nonprofit medical and hospital service corporations, proposes to authorize the creation of dental expense indemnity service plans Dental expense indemnity would consist of reimbursement for dental care provided through duly licensed dentists and of furnishing necessary appliances, drugs, medicines and supplies, prosthetic appliances, orthodontic appliances, precious metal and ceramic restorations

Bills Passed—A 896 passed the assembly February 18 To amend the law relating to the practice of optometry, it proposes that applicants must be citizens of the United States or must have declared an intention of becoming such A 898 passed the assembly February 18 To amend the law relating to the practice of podiatry, it proposes that applicants must be citizens of the United States or must have declared an intention of becoming such

Coming Medical Meetings

Aero Medical Association Chicago April 7 9 Dr David S Brachman, 1016 Dime Building Detroit 26 Secretary
Alabama Medical Association of the State of, Birmingham April 16 18 Dr Douglas L Cannon, 519 Dexter Ave, Montgomery 4, Secretary
Alaska Territorial Medical Association, Juneau, March 11 13 Dr William P Blanton Juneau Secretary
American Association of Anatomists, Cleveland, April 4 6 Dr Eliot R Clark University of Pennsylvania School of Medicine, Philadelphia 4, Secretary
American Association of Pathologists and Bacteriologists Chicago March 8 9 Dr Howard T Karsner 2085 Adelbert Road Cleveland Secretary
American Physiological Society, Atlantic City, March 11 15 Dr Wallace O Fenn 260 Crittenden Blvd, Rochester 7, New York Secretary
American Society for Experimental Pathology, Atlantic City, March 11 15 Dr Harry P Smith 630 W 168th St, New York 32, Secretary
American Society for Pharmacology and Experimental Therapeutics, Atlantic City, March 11 15 Dr Raymond N Bieter, University of Minnesota Medical School Minneapolis, Secretary
American Surgical Association Hot Springs Va, April 2 4 Dr Warfield M Firor, Johns Hopkins Hospital, Baltimore 5, Secretary
Arkansas Medical Society, Little Rock, April 14 15 Dr W R Brooksher 602 Garrison Ave Fort Smith Secretary
Central States Dermatological Society, Detroit April 27 Dr Clarence E Reyner Henry Ford Hospital Detroit, Secretary
Chicago Medical Society Annual Clinical Conference Chicago, March 5 8 Dr Warren W Furey, 30 North Michigan Ave Chicago 2, Secretary.
Dallas Southern Clinical Society Dallas Texas March 18 21 Dr. John G Young 1719 Pacific Avenue Dallas 1 Director of Clinics
Federation of American Societies for Experimental Biology, Atlantic City, March 11 15 Dr D R Hooker, 19 West Chase Street, Baltimore 1, Secretary
Florida Medical Association, Jacksonville, April 22 24 Dr Robert B McIver, P O Box 1018, Jacksonville, Secretary
Iowa State Medical Society, Des Moines, April 17 19 Dr John C Parsons 406 Sixth Ave, Des Moines 9, Secretary
Kansas Medical Society, Wichita April 22 25 Dr F R Croson, 112 W Sixth St, Topeka, Secretary
Medical Library Association, New Haven, Conn, March 25 27 Miss Frida Pliefke, 2006 Medical Arts Bldg Minneapolis 2 Secretary
Missouri State Medical Association St Louis, March 24 26 Dr Ralph L Thompson, 634 N Grand Blvd, St Louis 3, Secretary
New Orleans Graduate Medical Assembly, New Orleans April 1 4 Dr Joseph S D Antoni, 1430 Tulane Ave, New Orleans 13 Secretary
Postgraduate Institute of the Philadelphia County Medical Society, Philadelphia, April 9 12 Dr George P Muller, 301 S 21st St, Philadelphia, Director
Southeastern Surgical Congress, Memphis Tenn, March 11 13 Dr Benjamin T Beasley 45 Edgewood Ave S E Atlanta 3 Georgia Secretary
Tennessee State Medical Association Knoxville April 9 11 Dr W M Hardy, 706 Church Street Nashville Secretary

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education and public health.)

ALABAMA

Charles Thigpen Honored on Eightieth Birthday.—The Montgomery County Medical Society gave a dinner on January 15 in honor of Dr. Charles A. Thigpen, Montgomery, who on December 19 observed his eightieth birthday. Dr. Thigpen served as president of the Medical Association of Alabama in 1935. The previous year he had received the honorary degree of doctor of laws from the University of Alabama.

Changes in Health Officers.—Dr. Arthur M. Shelamer, Athens, has been appointed health officer of Madison County. Dr. Maurice M. Duncan, Huntsville, has been serving in the position since Dr. William C. Hatchett, Huntsville, resigned to join the Florida State Department of Health. Dr. Carl A. F. Holler, Fort Payne, has resigned as health officer of DeKalb County to accept a similar position in Etowah County with headquarters in Gadsden, effective February 1.

CALIFORNIA

University News.—The Stanford University School of Medicine, San Francisco, announces that the Winthrop Chemical Company has extended for another two years its fellowship for the training of medical graduates in the teaching and research of pharmacology.

Industrial Hygiene Change.—Dr. Douglas G. MacPherson, Van Nuys, formerly director of the Los Angeles City division of industrial hygiene, has been appointed chief of the Los Angeles County division of industrial hygiene. He succeeds Dr. Hugh Dierker Jr., Los Angeles, who has become medical director of the southern California division of General Motors.

Medical Veterans Organized.—Dr. William H. Leake, Beverly Hills, was named president of the Medical Veterans at its organization meeting in Los Angeles January 4 and Dr. Frederick A. Bennetts, Los Angeles, secretary. An executive committee was formed and directed to prepare a constitution and by-laws. The immediate objective of the new organization is to assist physicians returning from service in reestablishing their practice. Such problems as office space, purchase of surplus medical property, delay in obtaining narcotic licenses and ineligibility of physicians on terminal leave to the educational and loan provisions of the G. I. Bill of Rights will be studied through specially appointed committees.

CONNECTICUT

Personal.—Dr. Emerick Friedman, senior physician at the Norwich State Hospital, has been promoted to clinical director, effective February 1.

The Building Fund.—The original goal of $50,000 for the building fund of the Connecticut State Medical Society has been passed. Funds will continue to be solicited, however, in the face of uncertain building costs.

DELAWARE

Society News.—Dr. Thomas M. Durant, associate professor of medicine, Temple University School of Medicine, Philadelphia, addressed the New Castle County Medical Society in Wilmington, January 15, on "Recent Advances in the Etiology and Treatment of Coronary Heart Disease." Dr. Joseph Stokes Jr., professor of pediatrics, University of Pennsylvania School of Medicine, Philadelphia, addressed the society, February 19, on "Influenza and Virus Pneumonia."

GEORGIA

Grants for Research.—Frederick Stearns and Company, Eli Lilly and Company and Ciba Pharmaceutical Products, Inc., have established grants to the pharmacology department of the University of Georgia School of Medicine, Augusta, totaling $5,400 for the year of 1946. These funds are to support fellowships and technical help in investigating the pharmacology of the uterus in pregnancy and dysmenorrhea. One of these fellowships will be available in September 1946, with opportunity for the fellow to take part time medical work.

The Fischer Awards.—Dr. C. Dixon Fowler has received the Dr. Luther C. Fischer Award for the paper showing the best original research on "A Study of Malaria on Island X in the Pacific," and Dr. Roy S. Leadingham, both of Atlanta, the Fischer Award for the best written paper on "The Medical History in Physical Diagnosis." The prizes are awarded through the Fulton County Medical Society and honor Dr. Fischer, one of the founders of the Atlanta School of Medicine, where he was professor of anatomy and clinical surgery. The awards, consisting of $100 each, were established by Dr. Fischer in 1925.

ILLINOIS

X-Ray Testing Program.—On January 10 Gov. Dwight H. Green was the subject of the first x-ray in the mobile x-ray unit which is a part of a new initiated tuberculosis program conducted by the Illinois State Department of Public Health. The service is being offered to the people of the state free of charge.

Changes in Division Heads.—Lieut. Col. G. Howard Gowen has been appointed chief of the division of cancer control in the department of public health, effective March 1. Dr. Gowen graduated at the Northwestern University Medical School, Chicago, in 1926. He was epidemiologist for the state department of public health in 1936 and 1937. Thereafter he served as health officer of Champaign-Urbana, as administrative assistant in the Chicago Board of Health and as a member of the faculty of the Graduate School of Public Health at the University of Michigan Medical School, Ann Arbor. Lieut. Comdr. John F. Shronts, on terminal leave after nearly four years' service in the navy, has been named chief of the division of industrial hygiene, effective March 10. The position was formerly held by Dr. Milton H. Kronenberg, who resigned to become assistant to the medical director at the Caterpillar Tractor Company, Peoria. (The Journal, Oct. 14, 1944, p. 444). Dr. Shronts graduated at Northwestern University Medical School in 1936. Prior to entering the navy he was district health superintendent for the state department of public health with headquarters at Woodstock.

Chicago

The Ludvig Hektoen Lecture.—The twenty-second Ludvig Hektoen Lecture of the Frank Billings Foundation will be delivered at the Palmer House, March 22, by Dr. Simeon B. Wolbach, Shattuck professor of pathologic anatomy, Harvard Medical School, Boston. His subject will be "Vitamin A Deficiency and Excess in Relation to Skeletal Growth."

Placement Service for Psychiatrists.—The Illinois Society for Mental Hygiene announces a new placement service for psychiatrists at 343 South Dearborn Street. A complete roster of opportunities for employment, education and fellowships in Illinois will be set up for the convenience of applicants. Inquiries may be addressed to Dr. Rudolph G. Novick, Elgin, Ill., medical director of the society. The society for mental hygiene opened a series of lectures February 1 with a talk by Dr. David Slight on "Who is Normal?" The second lecture was given by Dr. Slight February 8 on "Who is Abnormal?" Dr. John P. Spiegel explained February 14 what a psychiatrist's treatment consists of and Mr. Louis De Boer, February 21, the importance of prevention and what preventive services are available.

INDIANA

George Brother Heads New Bureau.—Dr. George M. Brother, Indianapolis, recently released from military service, has been placed in charge of a new bureau of preventable diseases of the Indiana State Board of Health. The bureau will include the divisions of tuberculosis control, venereal disease control, industrial hygiene, dental health, adult hygiene and geriatrics, and communicable disease control. According to the *Journal of the Indiana State Medical Association*, grouping of these several divisions with related activities into one bureau will facilitate coordination and administration of activities and result in a more effective preventable disease program. Previous to his enlistment, Dr. Brother organized District Health Department Number 4 in the southeastern part of Indiana and later served as director of the division of local health administration with the state board of health.

KENTUCKY

Survey of Hospital Facilities.—Dr. William B. Atkinson, Campbellsville, formerly state medical officer for Selective Service, has been named acting director of a newly created division of medical and related services in the state department of health. The first activity of the division is to be a survey of hospital and nursing facilities as well as a study to determine the number of physicians in the state. The new division is the result of an executive order of Governor Simeon S. Willis.

Changes in State Health Personnel.—Dr. William F. Lamb, Russellville, recently returned from military service, has been appointed director of the division of venereal disease of the state department of health. Dr. Wayne L. Ritter, Louisville, on leave from the U. S. Public Health Service, has resigned as director of the bureau of industrial hygiene. Mr. W. W. Stalker is currently acting director of the division. Mr. Charles E. Tucker, recently released from military service, has been named educational director of a new cancer control program inaugurated by the state department of health in cooperation with the Kentucky Field Army of the American Cancer Society.

Physician Honored.—Dr. John M. Ryan, Carrollton, has been selected as the recipient of the Citizenship Award given each year by the Carrollton Chamber of Commerce to the man who, in the opinion of the organization, has rendered most valuable service to the community during the year. The citation accompanying the award announced that, "in view of his unselfish devotion to duty not only during the year of 1945 but also during the trying times forced on us by the shortages in his field during World War II, and being mindful of his contribution not only in time and in money but particularly the sacrificing of his personal health, we respectfully suggest that the Citizenship Award for the year 1945 be conferred on Dr. John Maxwell Ryan."

MARYLAND

Personal.—Dr. Joseph P. Franklin, Cumberland, who has been on military leave since February 1941, has returned as deputy state and county health officer of Allegany County.

Borden Award Goes to Edwards Park.—The American Academy of Pediatrics presented to Dr. Edwards A. Park, Baltimore, the Borden Award, consisting of a medal and $1,000. The award is granted annually to the specialist considered to have done the best research in nutrition in the field of pediatrics. Dr. Park's work was in nutrition to combat rickets. He graduated at Columbia University College of Physicians and Surgeons, New York, in 1905 and is professor of pediatrics at Johns Hopkins University School of Medicine, Baltimore.

MASSACHUSETTS

Ether Centenary.—Plans are now being made to observe the one hundredth anniversary of William T. G. Morton's demonstration of the use of ether for anesthesia. It is planned tentatively to hold symposiums during the days of October 14-16 and a special commemorative dinner Monday evening October 14.

Hugh Cabot Memorial Fund.—Two million dollars will be sought in a campaign by the Hugh Cabot Memorial Fund to erect a penicillin research laboratory and plant in Russia. Harlow Shapley, ScD., director of the Harvard Observatory and chairman of the national committee of the fund, indicated in a statement to the press that a campaign would be launched at a dinner February 13. Dr. Hugh Cabot died Aug. 14, 1945.

New Appointments in Physiology.—Hans O. Haterius, Ph.D., professor of physiology, Wayne University College of Medicine, Detroit, has been appointed professor of physiology and chairman of the department of physiology in the Boston University School of Medicine. Dr. George L. Maison, formerly assistant professor of physiology at Wayne University, has been appointed associate professor of physiology at the medical school. Dr. Maison recently was released from the Army of the United States, where he was engaged in aeromedical research. For his work in developing the anti-G suit Dr. Maison was awarded the Legion of Merit.

Camp Miles Standish Proposed as School for Adult Mental Defectives.—The Massachusetts Department of Mental Health, as soon as Camp Miles Standish was declared surplus property, applied to the government for purchase of the site for an institution for the care of mentally defective persons. At present it is planned that the institution will be used as an industrial and agricultural training school for the adult mental defectives who are transferred from the present schools. The vacancy thus created in the older schools will be for the admission of younger mental defectives who may be suitable for educational programs. It is planned that the institution shall have a final capacity for 2,000 mental defectives.

MICHIGAN

Changes in Health Personnel.—Dr. Robert R. Scott, Beulah, recently released from military service, has been appointed director of the Mason County Health Department. Dr. Robert L. Loftin, Cynthiana, Ky., who recently resigned as health officer of Harrison County, is the new health officer of the Bay City-Bay County Health Department. Dr. Edward F. Fisher, Dearborn, resigned the presidency of the Dearborn City Council to become director of the Dearborn Department of Health and Recreation.

New Public Relations Counselor.—Hugh W. Brenneman, recently returned from navy service as a destroyer communication and public relations officer, was on January 19 appointed public relations counsel for the Michigan State Medical Society, with headquarters at the executive offices in Lansing. Mr. Brenneman, since his graduation from Alma College in 1936, has had varied experiences, including service with the Associated Press, as a radio announcer and as president of the Wexford-Missaukee Teachers Association.

MINNESOTA

Medical School Cooperates in Care of Veterans.—A plan to add 146 physicians to the Veterans Administration Hospital, Minneapolis, through the cooperation of the University of Minnesota Medical School, was announced January 13. The program is the outgrowth of a law passed recently by Congress creating a bureau of medicine and surgery within the Veterans Administration. The program will add 35 men with rank of senior consultant, 43 consultants and 68 resident physicians or fellows. It provides placing of veterans' hospital standards on university medical school standards through direct supervision of all appointments of doctors by the dean of the university medical school; introduction of specialists drawn from all parts of the nation under supervision of a university "Dean's Committee"; setting up a fellowship system under which 68 university graduate doctors will work in the veterans' hospital on a full time basis while obtaining specialists' ratings, and ability instead of civil service status as the primary basis for appointment of physicians, with veterans given voluntary preference wherever possible. The program is similar to one described in The Journal, February 2, page 297, and to those planned for ten additional veterans' hospitals through cooperation of forty-six approved medical schools. Under the program 35 senior consultants, all specialists, will be appointed to make rounds in the hospital, aid in the treatment of special cases, hold conferences with the new staff and present resident doctors and act as consultants in difficult rehabilitation cases. The 43 men of "consultant" rank will comprise a visiting staff, spending roughly half of their time at the hospital and holding responsibility for the patients. Another 68 ward officers or resident doctors authorized will be full time resident doctors attending patients. They will be a "highly selected" group of university graduates, recommended by Dr. Harold S. Diehl, Minneapolis, who have finished internships, have had three or more years of military service and have some graduate training beyond internship. All senior consultants and consultants will be men who have qualified for certification by examining boards as specialists. Authorized by the national Veterans Administration are 61 men in surgery and surgical specialties, 65 in medicine and medical specialties and 20 in laboratory and x-ray specialties.

MISSOURI

First Hanau W. Loeb Lecture.—The first annual Hanau W. Loeb Lecture was given by Edward A. Doisy, Ph.D., St. Louis, at the St. Louis Medical Society Auditorium, December 10. He discussed "Vitamin K."

Ninety-Seven Years of Age.—Dr. Jacob D. Smith, Shelbina, observed his ninety-seventh birthday January 25. Dr. Smith graduated at Rush Medical College, Chicago, in 1870, first locating in Shelbyville. Dr. and Mrs. Smith on February 20 celebrated their seventy-third wedding anniversary. Mrs. Smith is 94 years of age.

Returning Faculty Members Honored.—A dinner was held in the Hotel Statler February 27 by the Rev. Alphonse M. Schwitalla, S.J., dean of the St. Louis University School of Medicine, and the administrative board, to welcome the 70th General Hospital and faculty members returning home from service. Speakers at the dinner included Major Gen. George F. Lull, U. S. Army, and Capt. Francis J. Braceland (M.C.), U.S.N.R.

Chemists Win Award.—Drs. Carl F. and Gerty T. Cori, head of the department of pharmacology and associate professor of biochemical research, respectively, Washington University School of Medicine, St. Louis, on February 3 were announced as co-winners of the second annual Midwest Award of the St. Louis section of the American Chemical Society. The award, a gold medallion, is made annually by the St. Louis section in recognition of "meritorious contribution to the advancement of pure or applied chemistry or chemical education." The formal presentation will take place March 21. The Coris received the award for their studies of the biochemistry of enzymatic reactions involved in carbohydrate metabolism. Both physicians graduated at the Deutsche Universität Medizinische Fakultät, Prague, Czechoslovakia, in 1920.

NEW YORK

Max Poser Dies.—Max H. Poser, known for his research in the field of optics, died in his home in Rochester, January 4, aged 75. In 1937 Dr. Poser was made a life technical adviser of the American Academy of Ophthalmology and Otolaryngology.

Fifty Thousand Dollars for Cancer.—Under the will of Mrs. Ruth Wheelock, who died Nov. 26, 1945, the bulk of her "more than $50,000 estate will go to the University of Rochester School of Medicine and Dentistry . . . to become a part of its cancer research fund."

Colgate Plans Medical Service.—With the appointment of Dr. John H. Rathbone as university physician and director of the department of student health at Colgate University, announcement was made that the university was making plans for a new medical center which would service the community as well as the student body and faculty. Dr. Rathbone is the prospective director of the center. An alumni representative on the board of trustees, Dr. Rathbone has been a member of the faculty of the Columbia University College of Physicians and Surgeons since 1931.

Personal.—Dr. John C. Eccles of the University of Otago, New Zealand, lectured at a conference sponsored by the New York Academy of Sciences, February 8-9. Dr. Eccles, who attended the conference at the request of the Rockefeller Institute for Medical Research, spoke on "Physicochemical Mechanism of Nerve Activity."——Dr. Donald C. O'Connor, Buffalo, has been named superintendent of the Edward J. Meyer Memorial (City) Hospital to fill the vacancy that occurred when Dr. William T. Clark, Buffalo, resigned on July 1, 1945.——Dr. Bernard S. Strait, Penn Yan, was installed as state Kiwanis governor at a convention in Albany, January 20.——Dr. Hugh H. Shaw on December 31 resigned as health officer of Utica after holding the position for twenty-six years.

State Care for Defective Infants.—The New York State Department of Mental Hygiene, at the direction of Governor Thomas E. Dewey, will accept into its institutions a limited number of mentally defective infants under the age of 5. The change in policy is due to the wartime increase in the number of infant defectives, making it impossible for local facilities and private families to continue to carry the main responsibility for their care. While the number will be limited, when the postwar building programs are completed at the state schools for defectives the number admitted will be greatly expanded. Only the most urgent cases will be granted immediate admission, cases which, in the opinion of department investigators, will grant immediate relief to the infant or the infant's family. The policy of the state for many years has been against accepting infant defectives into its institutions, except for occasional emergency cases, on the theory that the care of defective infants under 5 was primarily the responsibility of the family or the local welfare units, since the nursing factor in those cases usually outweighs the mental care. A $17,000,000 postwar building expansion program at the six state schools for the mentally defective and at Craig Colony for the Epileptic has been authorized, and an additional $2,000,000 program to build children's hospitals at four of these institutions has been proposed.

Druggist Guilty of Fatal Sulfonamide Dosage.—Jacob Greenwald, East Elmhurst, Queens, was convicted February 11 on a charge of second degree manslaughter following the death of a baby after being treated with six times as much sulfathiazole as a physician prescribed. The excessive dosage was considered a druggist's error and Greenwald was sentenced to a minimum term of one to two years in Sing Sing. Execution of the sentence was stayed and a certificate of reasonable doubt was granted which has the effect of an appeal and calls for a ruling by the appellate division before the sentence can be carried out, newspapers reported. Commenting that this was the first sulfathiazole case in the criminal courts of New York, Judge Thomas Downs said he believed the five judges of the appellate court should review the conviction because of "the unknown lethal qualities" of the drug. During the trial Alexander O. Gettler, Ph.D., New York toxicologist, and Dr. Jacob Werne, Jamaica, assistant medical examiner, testified that medical science does not know just what constitutes a lethal dose of sulfathiazole. Testimony showed a physician had prescribed 21 grains of the drug to be administered at the rate of 3 grains each four hours. Greenwald said he misconstrued the prescription and gave the child's father 147 grains in 7 grain doses. The baby got doses of 21 grains each four hours for twenty-four hours, a total of 126 grains.

New York City

University News.—Sharp and Dohme, Inc., has given $2,200 to Columbia University College of Physicians and Surgeons in support of Dr. Erwin Brand's work on proteins and amino acids.

Pamphlet on Syphilis.—The Community Service Society of New York City prepared a pamphlet on syphilis for the use of nurses doing family work. The pamphlet is made available at 5 cents a copy on orders of 1 to 100 and 4 cents on orders of over 100. The Department of Educational Nursing can be addressed at 105 East 22d Street, New York 10.

Alumni Day.—On February 22 the Alumni Association of the New York University College of Medicine held its tenth annual Alumni Day. The program included a scientific session and a dinner in the evening in honor of Dr. Arthur M. Wright, who has announced his retirement as George David Stewart professor and chairman of the department of surgery. Among the speakers were:

Drs. Hervey C. Williamson, Currier McEwen and Luther E. Holt Jr., A Reevaluation of the Vitamins.
Dr. Colin M. MacLeod, Certain Aspects of Chemotherapy.
Dr. Frank W. CoTui, *Protein Metabolism* in Disease and Injury.
Dr. Leonard J. Goldwater, Group Medical Practice.

A feature of the dinner honoring Dr. Wright was the presentation to Harry W. Chase, chancellor of the university, of a check for $575,000, representing the amount raised by the Alumni Association in its five month [illegible] of an auditorium in the new New [illegible] Medical Center.

Whipple Award to "Josie and Trixie."—On February 6 the American Museum of Natural History and the Friends of Medical Research presented a preview of a new exhibit, "Really Man's Best Friend." A feature of the event was the presentation of the first Whipple Award to "Josie and Trixie" of the School of Medicine and Dentistry of the University of Rochester. The dogs are the descendants of the original dogs used by Dr. George H. Whipple, Rochester, in his research on anemia. This award, established by the Friends of Medical Research and named for Dr. Whipple, who was given the Nobel Prize for research which led to the development of liver therapy for pernicious anemia, took the form of two leather collars bearing silver tags on which were described the services of the dogs in acting as experimental animals in blood plasma research. Josie and Trixie were brought to the ceremonies at the Museum of Natural History by Dr. Frieda S. Robbins, Rochester, Dr. Whipple's research associate of many years.

Residencies and Fellowship in Physical Medicine.—As one phase of its program of teaching and research in the field of physical medicine, the faculty of Columbia University College of Physicians and Surgeons, with the cooperation of a group of its affiliated hospitals, has established residencies and fellowships to provide training in physical medicine on a graduate level. The first group of residents were to be appointed by the hospitals before March 1 and will spend the months of April through June in an introductory course before beginning clinical work in the hospitals. For residencies the annual stipend varies with the hospital but includes maintenance or its equivalent. Applicants must have graduated from a medical school and have completed an internship approved by Columbia University. Applications should be submitted to the directors of the following hospitals:

Presbyterian Hospital, 620 West 168th Street, New York 32.
New York Post-Graduate Medical School and Hospital, 303 East 20th Street, New York 3.
Mount Sinai Hospital, Fifth Avenue at 100th Street, New York 29.
St. Luke's Hospital, 421 West 113th Street, New York 25.
Goldwater Memorial Hospital, Welfare Island, New York.
Montefiore Hospital, 150 East Gunhill Road, New York 67.
Hospital for Joint Diseases, 1919 Madison Avenue, New York 35.

A limited number of those who have completed the first or second years of the residency may apply for fellowships in physical medicine in Columbia University under a grant from the Baruch Committee on Physical Medicine. Fellowships are devoted to basic research related to physical medicine. The annual stipend is $2,500 without maintenance.

OREGON

Health Board Activities.—The Oregon State Board of Health will soon move to new quarters at Southwest Eleventh Avenue and Salmon Street in the building formerly occupied by the Behnke-Walker business college. The action follows approval at the annual board meeting in Salem of a five year lease on two floors of the building. Recent sale of the Oregon building, in which the board now has offices, brought about the change. Changes in personnel approved by the board include the resignation of Dr. Donald J. Bourg, The Dalles, as director of the division of maternal child health. The appointments of Dr. Daniel C. Kelley, Lawrenceville, Ga., as health officer of Clatsop County and the reinstatement of Dr. Richard Wilcox, Pendleton, recently returned from military service, as health officer of Umatilla County, have been announced.

TENNESSEE

Twenty-Five Years as Health Officer.—Dr. John J. Lentz on December 8 completed twenty-five years as director of the Davidson County Health Department, Nashville.

New Pediatric Head at Tennessee.—Dr. Frank T. Mitchell, Memphis, has been appointed professor and head of the department of pediatrics at the University of Tennessee College of Medicine, Memphis. He succeeds Dr. Edward C. Mitchell, who has been named emeritus professor. Dr. James G. Hughes has been promoted to associate professor of pediatrics and will devote his full time to the department.

Postgraduate Activities.—A postgraduate medical extension course in gynecology by Dr. Joseph R. B. Branch, Macon, Ga., has just closed in West Tennessee. In Memphis the registrations were so many that it was necessary to divide the Memphis group into three sections with the Millington Navy Base Medical Officers' meeting at John Gaston City Hospital with a total of forty-seven registered, the Army Medical Officers' meeting at Kennedy General Hospital with a total of forty registered, and with physicians in civilian practice of Shelby County and vicinity meeting at Methodist Hospital with a registration of 199. The course by Dr. Branch has already functioned over a period of a year in Tennessee and has included five circuits of twenty-two teaching groups with a total registration of 590. January 17 he opened a course in Nashville and vicinity with centers at Clarksville, Springfield and Dickson. The course will be given also for a group of medical officers at Camp Campbell, Meharry Medical College for a colored group and his final lecture each week with physicians of Nashville at Nashville General Hospital. This course in gynecology has been very popular among both medical officers of Tennessee on duty in various camps of army and navy establishments as well as civilian practitioners. Dr. Branch, the instructor, has just rounded out three years of postgraduate teaching in Tennessee. His first two years were spent in giving a course in surgical diagnosis in which 1,418 physicians registered and took the course in forty-seven teaching centers. One more year of instruction in gynecology in other areas in Tennessee will be given by Dr. Branch. The program is financed by contributions from the Commonwealth Fund of New York, the Tennessee State Health Department and the two medical schools of Vanderbilt and the University of Tennessee, and appropriations from the treasury of the Tennessee State Medical Association plus fees of the physicians. Mr. L. W. Kibler, who recently resigned as field director of the postgraduate course conducted by the postgraduate committee of the Oklahoma State Medical Association, now occupies a similar position with the committee on postgraduate instruction in gynecology of the Tennessee State Medical Association.

VIRGINIA

Coroner Goes to Korea as Missionary.—Dr. Robert Wilson, since the fall of 1941 city coroner of Richmond, is returning to Korea early in the new year to resume his medical missionary work, which was interrupted by the war. Prior to returning to America, Dr. Wilson had spent more than thirty years in Korea.

Joseph Barrett Named Mental Hygiene Head.—Dr. Joseph E. Barrett, Marion, superintendent of the Eastern State Hospital, Williamsburg, has been appointed commissioner of the Virginia State Department of Mental Hygiene and Hospitals. He succeeds Dr. Hugh C. Henry, who died Oct. 14, 1945. The position at the time Dr. Henry assumed it was a newly created one provided in the state government reorganization act, effective July 1, 1942. Dr. Barrett, who graduated at the University of Tennessee College of Medicine, Memphis, in 1922, formerly was director of the Michigan state hospital commission and assistant commissioner of the Massachusetts Department of Mental Hygiene.

GENERAL

National Noise Abatement Week.—April 28-May 4 has been designated National Noise Abatement Week, with the establishment of noise control on the agenda of all cities by city planning commissions as the keynote of the campaign.

Joe Savage Named Executive Director of Infantile Paralysis.—Mr. Joe W. Savage, Charleston, W. Va., who was recently discharged from the Army Air Force with the rank of major after more than three years' service, has been given the title of executive director of the National Foundation for Infantile Paralysis, it was announced February 13. The appointment of Mr. Savage to the foundation was reported in The Journal, Oct. 6, 1945, page 472.

Plotz Foundation for the Advancement of Scientific Investigation.—During 1945, the twenty-second year of the Ella Sachs Plotz Foundation for the Advancement of Scientific Investigation, thirty-eight applications for grants were received by the trustees, twenty-five of which came from the United States, the other thirteen coming from five different countries in Europe, Asia and North and South America. In the twenty-two years of its existence the foundation has made 531 grants, which have been distributed to scientists throughout the world.

Panel on Juvenile Delinquency.—Twenty-eight persons, each prominent in his field, were named by Attorney General Tom C. Clark February 9 as a national volunteer advisory panel to study the growing problem of juvenile delinquency. The attorney general said that the panel was not limited to the number announced and that others would be named from time to time. The panel was created to assist the department of justice in the formulation of plans to combat the upsurge in serious crimes being committed by teen-agers, both boys and girls.

Scott Awards Go to Goodpasture and Cohn. — On January 17 the John Scott Award, given by the Philadelphia Board of City Trusts, went to Dr. Ernest W. Goodpasture, professor of pathology and dean of the Vanderbilt University School of Medicine, Nashville, for his "development of a method for the cultivation of viruses that have made hitherto unknown vaccines possible." Edwin J. Cohn, Ph.D., professor of biochemistry, Harvard Medical School, Boston, received a similar award for developing "a substitute for dried blood plasma used in the treatment of shock in the war."

Examination in Orthopedic Surgery.—The American Board of Orthopaedic Surgery announces that examinations (part I) are scheduled to be given in New Orleans May 3-4, St. Louis and San Francisco May 10-11, and Philadelphia May 17-18. Applications must be received by the secretary on or before March 10. Part I of the examination will not be repeated until the spring of 1947. Part II will be given in Chicago in January 1947 preceding the meeting of the American Academy of Orthopaedic Surgeons. Correspondence and applications related to part I of the examinations should be sent to Dr. Guy A. Caldwell, 3503 Prytania Street, New Orleans 15. After July 1 all correspondence and applications for part II should be sent to Dr. Francis M. McKeever, 1130 West 6th Street, Los Angeles 14.

Arthritis Research Foundation Formed.—Establishment of a National Arthritis Research Foundation was announced at a meeting in the Blackstone Hotel, Chicago, February 10. A campaign for $2,500,000 will be launched to set up the foundation as a national and independent center for studying the cause and treatment of rheumatic diseases. The main buildings will be located in Hot Springs National Park. Present officers of the foundation include Judge A. B. Frey, St. Louis, president, and Mr. Walter W. Head, president of the General American Life Insurance Company, treasurer. As president of B'nai B'rith, which founded the Levi Memorial Hospital, Mr. Henry Monsky, Omaha, has been designated as honorary chairman of the campaign. Hon. Allen May, president, Mutual Life Insurance Company of St. Louis, is chairman of the insurance division. Mr. Louis Kranitz, St. Joseph, Mo., is chairman of the national campaign committee. The creation of the foundation stemmed from the plan of the Leo N. Levi Memorial Hospital, Hot Springs, Ark., to develop a research wing. Instead the hospital abandoned its own plans to assist in the creation of the national foundation.

Deaths

Henry Wellman Emile Walther ⊕ New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1910; born in New Orleans, Sept. 7, 1888; appointed professor and head of the department of urology at the Graduate School of Medicine of the Louisiana State University Medical Center in 1937; member of the House of Delegates of the American Medical Association from 1932 to 1935 and chairman of the Section on Urology, 1937-1938; specialist certified by the American Board of Urology, Inc.; member of the American Urological Association and co-founder of the Southeastern Branch, of which he had been president in 1936; treasurer of the Orleans Parish Medical Society, 1917-1918; co-founder and past president of the Louisiana Urological Society and the New Orleans Social Hygiene Society; member of the Southeastern Surgical Congress, American Neisserian Society, Southern Medical Association, serving as chairman of its section on urology in 1923, and the Louisiana State Medical Society, serving as chairman of its section on urology in 1927; fellow of the American College of Surgeons; vice president of the second Pan American Medical Congress; assistant surgeon, U. S. Public Health Service, during World War I; consulting urologist on the medical advisory board, Selective Service System, during World War II; served on the staffs of the Southern Baptist Hospital, Charity Hospital, U. S. Marine Hospital, Illinois Central Railway Hospital and the Hotel Dieu; member of the Art Association of New Orleans, serving as president from 1930 to 1934, Isaac Delgado Museum of Art, serving as vice president, and the Friends of the Howard-Tilton Memorial Library of Tulane University, of which he had been co-founder and past president; in 1937 resigned as editor of the *New Orleans Medical and Surgical Journal;* died January 6, aged 57.

William Jepson ⊕ Sioux City, Iowa; born in Aarhus, Denmark, June 29, 1863; State University of Iowa College of Medicine, Iowa City, 1886; University of Pennsylvania Department of Medicine and Jefferson Medical College, Philadelphia, 1891; licentiate of the Royal College of Physicians, Edinburgh, Royal College of Surgeons, Edinburgh, and Royal Faculty of Physicians and Surgeons of Glasgow, 1897; an Affiliate Fellow of the American Medical Association, serving as a member of its House of Delegates in 1906-1907, 1926, 1928, 1929 and 1930; past president of the state board of medical examiners, Tri-State Medical Society, Iowa Clinical Surgical Society, Iowa State Medical Society, Woodbury County Medical Society and the Sioux Valley Medical Society; past state chairman for the American Society for the Control of Cancer; member of the Western Surgical Association; fellow of the American College of Surgeons and the International College of Surgeons; since 1938 professor emeritus of surgery at the State University of Iowa College of Medicine in Iowa City, where he was professor and head of the department of surgery from 1902 to 1913; formerly professor of surgery at the Sioux City College of Medicine; served as a member of the faculty of medicine of the University of South Dakota; member of the founders group of the American Board of Surgery; surgeon of the 56th Regiment of the Iowa National Guard from 1907 to 1916 with the rank of major; during 1916 and 1917 served as surgeon of the Second Iowa Regiment on the Mexican border and during World War I was chief surgeon at the Base Hospital, Camp Bowie, Texas; active in establishing St. Joseph Hospital; died November 30, aged 82, of urinary obstruction and uremia.

Isaac Hall Manning, Chapel Hill, N. C.; Long Island College Hospital, Brooklyn, 1897; born in Pittsboro, Sept. 14, 1866; since 1939 Kenan professor emeritus of physiology at the University of North Carolina School of Medicine, where he had been professor of physiology since 1901 and dean from 1905 to 1933; in 1933 president of the Medical Society of North Carolina, of which he had been an honorary member; president of the Hospital Savings Association of North Carolina, Inc., from the time of its organization in 1935 until 1942, when he became chairman of the board of medical directors; member of the American Medical Association; fellow of the American College of Physicians; in 1940 the Alumni Association of the University of North Carolina School of Medicine presented his portrait to the university; died February 12, aged 79.

Allmond, Carrcroft, Del.; Hahnemann Medical College and Hospital of Philadelphia, 1889; formerly mayor and secretary of the board of health in Newark; at one time member of the Homeopathic Medical Society Examining Board; for many years on the staff of the Memorial Hospital, Wilmington, where he died November 2, aged 79.

Arthur G. Altham ⊕ Sheldon, Mo.; University Medical College of Kansas City, 1905; honorary member of the Missouri State Medical Association; died October 29, aged 66.

Jesse Earle Ambler ⊕ Ford City, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1908; found dead November 23, aged 66.

Edward Thomas Anderson, Excelsior, Minn.; Sioux City (Iowa) College of Medicine, 1897; served during World War I; died in the Veterans Administration Facility, St. Cloud, November 1, aged 76, of arteriosclerotic heart disease.

Sullivan Lane Andrews, Lewiston, Maine; Medical School of Maine, Portland, 1901; member of the American Medical Association; past president of the Androscoggin County Medical Society; fellow of the American College of Surgeons; past president of the staff of the Central Maine General Hospital, where he served for many years and where he died November 26, aged 68.

William A. Borin, Bartonville, Ill.; Medical Department of Grant University, Chattanooga, Tenn., 1891; member of the American Medical Association; on the staff of the Methodist Hospital in Peoria; died November 5, aged 79, of cerebral hemorrhage.

Patrick Stephen Brady, Hays, Kan.; Kansas City (Mo.) College of Medicine and Surgery, 1921; member of the American Medical Association; served during World War I; county health officer; on the staff of St. Anthony's Hospital; died November 12, aged 56, of coronary thrombosis.

James Henry Brennan, New Rochelle, N. Y.; Long Island College Hospital, Brooklyn, 1898; on the staff of the New Rochelle Hospital; died November 26, aged 72, of bronchopneumonia.

Henry Edward Briody, Paterson, N. J.; Jefferson Medical College of Philadelphia, 1909; died November 26, aged 65, of coronary occlusion.

Lester Rupert Brown ⊕ Laconia, N. H.; University of Vermont College of Medicine, Burlington, 1899; served as county coroner and as city and county physician; died November 1, aged 71, of coronary thrombosis.

William Bates Buckner, Jacksonville Beach, Fla.; Tulane University of Louisiana School of Medicine, New Orleans, 1935; member of the American Medical Association; first lieutenant, medical reserve corps, U. S. Army, not on active duty; in 1938 elected health commissioner of Dougherty County with headquarters in Albany, Ga.; served a residency at the Florida State Hospital in Chattahooche; died November 11, aged 39, of coronary thrombosis.

Thomas B. Budge, Logan, Utah; Northwestern University Medical School, Chicago, 1905; also a D.D.S.; fellow of the American College of Surgeons; served as associate medical director and head of the eye, ear, nose and throat department, William Budge Memorial Hospital; died November 22, aged 67, of hypertension and cerebral embolism.

Robert Hiram Butler ⊕ Bellefontaine, Ohio; Miami Medical College, Cincinnati, 1906; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; specialist certified by the American Board of Otolaryngology; served during World War I; president of the board of trustees of the Bellefontaine Library; died November 21, aged 64, of injuries received in an automobile accident.

Delia Caldwell, Carbondale, Ill.; Northwestern University Woman's Medical School, Chicago, 1896; formerly practiced in Paducah, Ky., where she served as president of the board of education; at one time vice president of the Kentucky State Medical Association; assistant professor, college physician, emerita, Southern Illinois Normal University; died November 28, aged 85, of nephritis.

Maggie Annettie Campbell, Davenport, Iowa; Hering Medical College, Chicago, 1905; died November 26, aged 86, of bronchopneumonia.

Emanuel Charbonneau, Van Nuys, Calif.; Milwaukee Medical College, 1909; served during World War I; contract surgeon in the U. S. Army; died in the DeWitt General Hospital, Auburn, November 23, aged 63, of bronchopneumonia secondary to carcinoma.

C. Hermann Claus ⊕ Newark, N. J.; Georg August-Universität Medizinische Fakultät, Göttingen, Prussia, Germany, 1919; on the staff of St. Vincent's Hospital, Montclair, where he died November 30, aged 54, of virus pneumonia.

Frank Di Cosola, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1912; served during World War I; on the staffs of the West Suburban Hospital, Oak Park, and the Mother Cabrini Memorial Hospital; died November 26, aged 57, of coronary occlusion.

Frederick Edward Dargatz ⊕ Kinsley, Kan.; University Medical College of Kansas City, Mo., 1913; served during World War I and as health officer of Edwards County and as director of the health unit of Ardmore, Okla.; died in the Bethel Deaconess Hospital, Newton, November 30, aged 59, of coronary occlusion and cerebral thrombosis.

William Rowland Davies ⊕ Scranton, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1899; past president and secretary of the Lackawanna County Medical Society; served as vice president of the American Physicians' Art Association; member of the House of Delegates of the American Medical Association, 1913-1914; chief surgeon on the staff and member of the board of directors of the West Side Hospital, where he died November 20, aged 70, of coronary thrombosis.

Louis George D'Elia, Jersey City, N. J.; University of Tennessee College of Medicine, Memphis, 1931; died November 25, aged 40, of coronary thrombosis.

Libeus Marshall Denman, Cincinnati; Cincinnati College of Medicine and Surgery, 1876; for many years a medical examiner for the Prudential Life Insurance Company; died November 30, aged 94, of hypertensive heart disease.

Nathan Freeman Doleman ⊕ Tintah, Minn.; Boston University School of Medicine, 1901; served as health officer; on the staff of St. Francis Hospital in Breckenridge; died in Wellington, Kan., November 8, aged 68, of arteriosclerosis.

John Edmund Doran, Atascadero, Calif.; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1898; died October 29, aged 73.

Helena Eleanor Enz, Kansas City, Mo.; Kansas City (Mo.) Hahnemann Medical College, 1912; died in the Trinity Lutheran Hospital November 25, aged 59.

John Robert Espey ⊕ Trinidad, Colo.; Jefferson Medical College of Philadelphia, 1889; past president of the Colorado State Medical Society; in 1930 member of the House of Delegates of the American Medical Association; fellow of the American College of Surgeons; served during World War I; major, medical reserve corps, U. S. Army, not on active duty; surgeon at the Mount San Rafael Hospital; died November 24, aged 81, of cerebral hemorrhage.

Maurice Exiner ⊕ Brentwood, N. Y.; University and Bellevue Hospital Medical College, New York, 1911; served during World War I; died November 23, aged 56, of coronary thrombosis.

Walter William Frank, Lombard, Ill.; Bennett Medical College, Chicago, 1910; examining physician for the local draft board, many insurance companies and civil service in the area bounded by Oak Park and the Fox River valley; died in Elmhurst November 23, aged 60.

Powell Beal Gardner ⊕ Guthrie, Okla.; Tulane University of Louisiana School of Medicine, New Orleans, 1915; member of the city council; on the staff of the Cimarron Valley Wesley Hospital; died November 26, aged 56, of coronary thrombosis and ileitis with gangrenous bowel.

Ross Holland Gregory, Fontanelle, Iowa; Kentucky School of Medicine, Louisville, 1893; died November 7, aged 75, of cerebral hemorrhage.

Cesidio Arthur Guarini, Boston; Middlesex College of Medicine and Surgery, Cambridge, 1919; died November 14, aged 53.

John Lewis Haddox, Knoxville, Tenn.; Tennessee Medical College, Knoxville, 1903; died in St. Mary's Hospital November 19, aged 72.

Frederick S. Halm, Sand Springs, Okla.; Kansas City (Mo.) Medical College, 1901; died in the Mercy Hospital, Tulsa, November 12, aged 67.

Paul E. Harper, Dry Ridge, Ky.; University of Louisville School of Medicine, 1935; member of the American Medical Association; interned at St. Elizabeth Hospital in Covington; began active duty in the medical corps, Army of the United States, on Oct. 1, 1942; relieved from active duty Nov. 1, 1944; died October 22, aged 35.

John Ramsey Harrison, Greer, S. C.; University of Tennessee College of Medicine, Memphis, 1923; died in the General Hospital, Greenville, November 22, aged 53, of a fractured skull received in a fall.

Evert Clarence Hartman ⊕ Janesville, Wis.; Northwestern University Medical School, Chicago, 1908; served as president of the Rock County Medical Society; served during World War I; affiliated with the Pember-Nuzum Clinic; member of the staffs of the Pinehurst Sanatorium and the Mercy Hospital, where he died November 30, aged 63, of coronary thrombosis and diverticula of the colon with hemorrhage.

Walter A. Hazelton, Hayward, Wis.; Chicago Homeopathic Medical College, 1892; died November 11, aged 77, of coronary occlusion.

Louis Kaufman Henschel, Huntington, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1906; served overseas during World War I; at one time surgeon in the U. S. Public Health Service Reserve; formerly on the staffs of the New Jersey State Hospital in Greystone Park, Bellevue Hospital and the U. S. Veterans Bureau in New York; died in the Huntington Hospital November 27, aged 66, of cardiovascular renal disease.

Harry Joseph Herzstein ⊕ Pittsburgh; Medico-Chirurgical College of Philadelphia, 1905; died November 26, aged 63, of coronary thrombosis.

Warren La Rue Hogue, Montpelier, Ohio; Michigan College of Medicine and Surgery, Detroit, 1890; died in Alvordton November 17, aged 82, of carcinoma of the lungs.

Spencer Stoddard Howe ⊕ Bellingham, Wash.; Rush Medical College, Chicago, 1903; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology and the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; served during World War I; on the staffs of St. Luke's General Hospital and St. Joseph's Hospital, where he died November 8, aged 69, of coronary occlusion.

William Johns ⊕ Wilkinsburg, Pa.; University of Pittsburgh School of Medicine, 1908; died November 19, aged 65.

Joseph Warren Johnson, Los Angeles; University of Arkansas School of Medicine, Little Rock, 1938; member of the American Medical Association; interned at the Los Angeles County Hospital; died November 12, aged 35.

Arthur Proschold Kaelber ⊕ San Francisco; Cooper Medical College, San Francisco, 1903; died recently aged 66.

John Lawrence Keane, Dubuque, Iowa; Creighton University School of Medicine, Omaha, 1926; member of the American Medical Association; died in Dyersville November 3, aged 49, of coronary embolism.

Marie Sarah Ella Kinner, Pittsburgh; Howard University College of Medicine, Washington, D. C., 1919; member of the American Medical Association; died in the Allegheny General Hospital November 30, aged 52, of glomerulonephritis.

Kristine Mann ⊕ New York; Cornell University Medical College, New York, 1913; died in the New York Hospital November 12, aged 71, of carcinoma of the breast.

William Elmer Marsh ⊕ Eldora, Iowa; State University of Iowa College of Medicine, Iowa City, 1891; served as secretary of the Hardin County Medical Society; died November 10, aged 79, of senility.

Hobart Earle Martin ⊕ Clinton, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1901; served two terms as president of the Clinton County Medical Society; member and past president on the staffs of the Jane Lamb Memorial and St. Joseph Mercy hospitals; member of the Iowa State Historical Society; died November 15, aged 67, of coronary thrombosis.

Conley Pinkney McEachern ⊕ Geneva, Ala.; Medical College of Alabama, Mobile, 1896; died November 19, aged 73, of cardiorenal disease and influenza.

John McQuade ⊕ San Francisco; College of Physicians and Surgeons of San Francisco, 1918; on the staff of Mary's Help Hospital; died November 17, aged 68.

Robert Mabry Miller ⊕ Belton, Mo.; St. Louis University School of Medicine, 1905; served three terms on the school board; president of the township board and bank president; died in the Research Hospital, Kansas City, November 9, aged 66, of coronary thrombosis.

Charles Burdette Pillsbury ⊕ Ypsilanti, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1918; specialist certified by the American Board of Radiology, Inc.; member of the Radiological Society of North America, Inc.; past president of the Washtenaw County Medical Society; on the staffs of the Ypsilanti State Hospital and the Beyer Memorial Hospital, where he died recently, aged 53, of coronary thrombosis.

Victor Strong Randolph ⊕ Phoenix, Ariz.; University of California Medical School, San Francisco, 1923; fellow of the American College of Surgeons; member of the American College of Chest Physicians; on the staffs of the State Welfare Sanatorium, Tempe, Good Samaritan and St. Joseph's hospitals; died November 6, aged 52.

William Isaac Robey, Herndon, Va.; George Washington University School of Medicine, Washington, D. C., 1902; member of the American Medical Association; died in Washington, D. C., October 5, aged 67.

Robert Hunter Scott, Newark, N. J.; Medical College of Virginia, Richmond, 1901; member of the American Medical Association; at one time professor of obstetrics at his alma mater; specialist certified by the American Board of Pediatrics, Inc.; on the staffs of the Babies Hospital-Coit Memorial, Newark City Hospital, Presbyterian Hospital and the Hospital of St. Barnabas and for Women and Children; died November 21, aged 69, of coronary thrombosis.

The Social Insurance Plan

Three years after the publication of the Beveridge report on social insurance a national insurance bill embodying the proposals, with a few modifications, has been formulated by the government. This measure is the climax of a socialistic trend in British legislation for many years. It should be remembered that the Beveridge plan was produced by a coalition government in which the conservative party was dominant.

The main weekly benefits under the bill are for sickness and unemployment $5, with $3 for a dependent and $1.50 for the first child; retirement pension $5, widow's allowance $7, maternity allowance $7, attendance allowance $4, maternity grant $16, death grant $80. The cost of benefits is estimated at $1,808,000,000 in 1949, of which about a third will be paid by the exchequer, which will also finance the cost of a family allowance plan, $240,000,000. For the employee the weekly contribution is $1 and for the employer $0.75.

Free medical attendance, which includes every form of treatment—general practitioner, consultant and specialist, domicilary and hospital—is to be provided for all. Details have not yet been published, as the negotiations with representatives of the medical profession are in progress and the decisions of the government remain to be announced. It is unfortunate that these will be made by a socialist government. With the previous coalition government a more balanced consideration of the various interests involved could be expected.

Cancer Research

The annual report of the British Empire Cancer Campaign is based on work done in many laboratories in Britain and the dominions. At the laboratories of the Middlesex Hospital an attempt was made to complete the synthesis of the stilbestrol series. It did not yield any substance of greater activity than diethylstilbestrol. Intensive research is being carried out on the metabolism of synthetic estrogens, especially in relation to cancer of the prostate and breast. At present the use of estrogens in inoperable cancer of the breast has not given conclusive results. A study of the pathology of cancer of the colon at St. Mark's Hospital shows a less malignant tumor to be more common in the colon than in the small intestine. The histology of the primary tumor, the extent of venous spread and the incidence of lymphatic metastases reveal that cancer of the colon is a relatively favorable field for surgery. In cancer of the rectosigmoid region about half the patients who survived a combined excision of the rectum were alive after five years. The best prospects of survival were found in cases without local spread beyond the rectal muscle, without detectable venous spread or lymphatic metastases. The survival rate in these patients was 82 per cent. At the Cambridge University Research Center studies were made by means of serial biopsies of the effects of x-rays and gamma rays. In carcinoma of the cervix anaplastic growths often fail to respond to irradiation. At the Marie Curie Hospital a study of the treatment of uterine cancer with radium was continued. Of 1,410 patients with cancer of the cervix treated over five years ago 36.9 per cent are alive. Radium alone appears to be the method of choice until a combined radium and x-ray technic can be found which will deliver adequate radiation without increasing intestinal morbidity. About 500 cases of cancer of the larynx and pharynx treated at London hospitals have been analyzed. Males predominated over females in a ratio of 10 to 1 except in the ropharynx, where the numbers were nearly equal, and in the id region, where there was a ratio of 3 women to 1 man. Only 19 of 384 persons with cancer of the pharynx survived five years, and 26 of 124 with cancer of the larynx. In early cases laryngofissure gave a survival rate of 91 per cent of the normal expectation of life over a five year period. An investigation was made as to the effect of tobacco and alcohol. Of 307 males 232 were said to smoke in moderation, 64 smoked to excess and 11 were nonsmokers. Of 291 patients 227 used alcohol in moderation and 27 to excess, while 37 were total abstainers.

Treatment of Acute Prolapse of the Uterus

A new treatment of acute prolapse of the uterus has been described in the *British Medical Journal.* It was discovered by accident. A woman aged 31 had been spontaneously delivered of her second child. As there was moderate hemorrhage, Credé's expression of the placenta was performed and the uterus became completely inverted. It was at once replaced in the vagina, but further manipulation was considered inadvisable because of shock. An obstetric surgeon, Mr. J. V. O'Sullivan, saw her seventy minutes after the inversion. She was pale and sweating, with a blood pressure of 80/50 and a pulse rate of 140. On separation of the labia the fundus of the uterus could be seen with the placenta. The treatment of shock included 3 pints of blood. Three hours later the patient had improved greatly and replacement by taxis was attempted with ether anesthesia. This caused rapid deterioration of her condition, so a douche was given preparatory to a later attempt. When the douche was given the tip of the nozzle, guarded by the fingers, was passed toward the posterior fornix. The surgeon's forearm blocked the vaginal orifice, the vagina ballooned out and the uterus promptly returned to its correct position. The signs of shock rapidly disappeared, and uninterrupted recovery followed.

In a second case inversion of the uterus took place in the third stage of labor, and two large tears occurred in an attempt to strip off the placenta. The patient's condition became desperate, with a blood pressure of 70/40. O'Sullivan saw her nine hours after inversion, when she had improved sufficiently to warrant further treatment. Under light open ether anesthesia the uterus was gently delivered through the vagina and the adjacent peritoneal cavity was inspected through the tears. The oviducts and ovaries were found normal. The two tears were repaired. Gentle taxis failed to replace the uterus. In spite of the ruptured uterus, which had been sutured, it was decided to attempt to replace it by hydraulic pressure. The vagina was distended to capacity by a dettol and proflavine douche, which was retained by blocking the outlet with the forearm aided by the assistant's hands. The position of the uterus was corrected, the douche can being held 2 to 3 feet above the vagina. Complete recovery followed.

O'Sullivan recommends immediate replacement of the uterus as soon as inversion occurs, before shock develops, without attempting to remove the placenta. If the patient is in shock, clean the uterus and change the complete inversion to an incomplete by gently replacing it in the vagina, then raise the foot of the bed, place a sterile pad on the vulva and treat for shock. When shock is controlled replace the uterus by hydraulic pressure, as described. Other obstetricians have reported cases in which hydraulic pressure was successful.

A Hospital for Tropical Diseases

In his presidential address to the Royal Society of Tropical Medicine and Hygiene Dr. C. M. Wenyon called attention to the present inadequacy of the facilities in London for the treatment and investigation of tropical diseases. In 1899 Manson founded at the London docks the School of Tropical Medicine and the Hospital for Tropical Diseases. This center functioned successfully until shortly after the war of 1914-1918, when it was removed to a more central position. Later the London School of Hygiene and Tropical Medicine was founded as a gift from the Rockefeller Foundation. For the first time the School of Tropical Medicine was separated from the Hospital for Tropical Diseases. In the recent war the hospital was evacuated and subsequently was so damaged that it had to be abandoned. There is now, Dr. Wenyon pointed out, a great opportunity for establishing in London a Tropical Medical Center with a hospital of 300 beds and all facilities for teaching and research. The reestablishment in London of a Tropical Medical Center would also assist in improving the health of the natives of our colonies, although large sums of money have been designated for this purpose alone.

The New Health Program

Dr. René Sand will publish through the Institute of Sociology an important work dealing with health conditions in Belgium and the necessary improvements. Advancement must include dissemination of practical knowledge of the rules of hygiene, an increase in the general well being and social security and the institution of certain measures such as the drainage of swampy regions, generalization of water distribution and drainage of lands as well as organizations of public health. The author is particularly concerned with the latter, which he believes should constitute an autonomous service independent of political influence. He foresees the creation of a national health service which would have among its assignments hygiene and all the branches of health service and the supervision of the professions and institutions of curative and preventive medicine. This service would include a national health council, regional health services, committees of coordination of communal and provincial health service and committees of coordination of public works and private institutions.

Conditions of Malnutrition in Belgium During the German Occupation (1940-1944)

Professor Brull and his collaborators have published a series of studies on the results of malnutrition in Belgium during the war. The effects on the public health due to privations undergone during the occupation are not all known as yet and it will take years before they can be definitely established. There is, however, a collection of facts which it was advisable to study even during these sad years. Investigation has established the value of whole grain bread; studies on adults and adolescents have shown that there was a general loss of weight and a parallel lowering of arterial tension, but the hemoglobin was maintained at a normal level. Hypoproteinemia, hypocholesteremia and a low phospholipid content of the blood was almost constant in young persons. Valuable conclusions were reached on the pathogenesis of hunger edemas, the condition of the heart and circulation and nitrogen metabolism in malnutrition.

Special Hospital for Poliomyelitis

The reappearance of infantile paralysis resulted in considerable confusion among the people. The information released by the Ministry of Public Health on this subject was of an alarming character. A special hospital was immediately designated by the Ministry of Public Health for the diagnosis and treatment of infantile paralysis. It must be recognized that by doing so the authorities evidenced unprecedented promptness. Dr. Leon Laruelle, president of the National League against Poliomyelitis and director of the Neurologic Center of Brussels, has specialized in the study of infantile paralysis. He was appointed to direct the activities required at such a time. The rapid shipment of four iron lungs was at once assured, thanks to the collaboration of the United States of America.

Dangers of Artificial Respiration

In an article in the *Scalpel* Hustin directs attention to the dangers in certain procedures of artificial respiration, which by various mechanisms exert a harmful influence on the circulation of the blood. An apparatus which utilizes the insufflation of air into the lungs under pressure hinders more or less the entrance of blood into the thorax and interrupts the venous circulation. The author has observed in a case of syncope in the course of a spinal anesthesia that the hemorrhage of the wound stopped at the time the respirator was put into action, and this effect was produced more rapidly because the blood pressure had previously been much below normal. The supine position of the patient in the apparatus of Paris and the strap which surrounds the lower part of the thorax greatly disturb the circulation in the abdomen and the lower extremities; the inclined plane on which the thorax rests only accentuates the epigastric compression, as may the obesity of the subject. Thus, to the inconveniences of a purely respiratory nature pointed out by André and Boxus with the apparatus of Paris there are added other disadvantages of this apparatus for the circulation. In estimating the value of a method of artificial respiration, it is necessary to consider not only the entrance and exit of the pulmonary air but also whether the intrathoracic circulation is hindered by the means employed to insure pulmonary ventilation.

Naval Medicine

During the recent war the Soviet navy was free from epidemics, although in preceding wars the loss of life from epidemics was higher than from combat. The mortality of seamen with various infectious diseases did not exceed prewar figures. These good results were due to various measures of control. Reinforcements for navy crews were temporarily quarantined from the regular personnel. Seamen returning from holidays, hospitals or leaves entered sanitary control stations for medical examination. At naval bases sanitary epidemiologic laboratories were established to inspect ships and coast troops, drinking water and food. They acted immediately to control infectious diseases. Antiepidemic measures were especially difficult to maintain on small war ships, which rapidly changed location and were often detached from bases for long periods. Mobile disinfection chambers, x-ray units, bath trains and laundry trains were utilized in the besieged seaports of Odessa, Leningrad, Sebastopol and certain arctic bases.

Battleships and cruisers carried experienced surgeons and adequate equipment so that surgical work could be performed on shipboard. But for personnel of smaller warships specialized medical and surgical work was performed in naval hospitals.

In order to provide medical care for the navy, spread over immense distances, "maneuver groups of strengthening" such as antiepidemic, surgical and transport groups were organized. A special system of closed evacuatory treatment provided for evacuation and complete medical service in naval hospitals.

As the result of treatment in the navy for the first forty-five months of the war 84.9 per cent of wounded and 96.4 per cent of diseased recovered and returned to service. These figures result from the excellent treatment and the work of numerous specialists, among them Prof. Julian Janelidze, the hero of Socialist Labor, and Professors Lisitzyn, Melnikov, Miasnikov, Púnin and Yassinovsky. During the war an institution of flag specialists was organized. The members of this medical staff took direct part in the medical practice of the navy.

Much attention was given to the study of professional injuries in the navy, especially for divers and crews of cutters, submarines and the navy air fleet. Recommendations were made for improving hydroacoustics, air regeneration, rational food supply and stimulation of the nervous system. The conditions were especially hard in the navy of the North Sea. Medical officers of submarines studied them directly while on ship board. Major Gusinsky of the medical corps worked out air regeneration tables for different types of submarines. He participated in eight campaigns.

The scientific and research medical work of the navy is planned by the scientific medical council of the medical sanitary administration of the navy and its sections. During the war eighteen volumes of transactions of the scientific medical council were published with about three hundred articles on different questions of naval medicine.

Special journals on naval medicine are issued, including the *Naval Military Surgeon, Military Medical Navy Transactions* and *Generalization of War Experience.* A great share of the credit for this work belongs to the director of the Navy Scientific Medical Institute, Professor Bykov, member of the Academy of Medical Sciences of the U. S. S. R., and to Professors Koiransky, Yakovenko, Podkopaiev and Frenkel as well as to the staff of the Naval Military Medical Academy.

BCG Immunization of the Allergic Healthy Adult

Dr. Arlindo de Assis, head of the tuberculosis laboratory of the Ataulpho de Paiva Foundation, is conducting a series of experiments to ascertain the mechanism of BCG immunization in man. In a paper recently published he reports the effect, on the human organism allergic to tuberculin, of the prolonged use of massive doses of the BCG immunizing material. Two volunteers previously tested with old tuberculin reacted respectively to Pirquet's test and to Mantoux's test (1:1,000). X-ray films in 1 case showed residual lesions of the hilus lymph nodes as well as of the right apex (Simon's nodules). The second volunteer presented only residual x-ray lesions of hilus lymph nodes. Both of them began then to ingest daily increasing doses of BCG, starting from 4.5 mg. and reaching progressively 10, 15 and finally 30 mg. The daily use of BCG was continued for six months in 1 case and for five in the other, totaling respectively 2.095 and 2.358 Gm. In both cases the general health condition was quite normal during the immunization period and after it was discontinued. The leukocyte counts evidenced a very slight increase of lymphocytes. Blood sedimentation tests remained unaffected in 1 case and showed inconclusive variations in the second. X-ray films were taken both during the immunization period and four to six months after the BCG ingestion had ceased. Pathologic changes could not be discerned in the original pulmonary findings of the cases. Tuberculin tests were periodically performed, evidencing a slight degree of desensitization of the skin specific allergy as the result of the daily absorption of BCG by the oral route. A gradual increase of tuberculin hypersensitiveness was again observed some time after BCG was discontinued.

Occurrence of Murine Virus of Choriomeningitis

In the examination of material from gray mice captured in Salvador, state of Bahia, Dr. Fulvio J. Alice has found a filtrable virus similar to the virus of choriomeningitis. In a preliminary paper Dr. Alice reported that a virus filtrable in Berkefeld W filters has been isolated from Bahia gray mice through peritoneal and intracerebral inoculation of guinea pigs. It has been possible to infect albino rats and mice, but rabbits and cats apparently are not susceptible. The blood serum of guinea pigs which recovered from the infection produced by inoculation of the strain under study contained antibodies capable of neutralizing the strain WE of the choriomeningitis virus. The inoculation of the WE strain could also neutralize, but only partially, the Bahia strain. Guinea pigs which recovered from the infection produced by inoculation of the SP4 strain were resistant to the reinoculation of the standard virus, which was lethal for apparently normal guinea pigs used as a control. In a new paper Dr. Alice confirms and enlarges on his previous findings. The virus isolated from gray mice on simultaneous intracranial and intraperitoneal inoculations into guinea pigs is filtrable in Berkefeld V, N and W filters. Guinea pig brain, liver, spleen and blood are infective to other guinea pigs through the cerebral, peritoneal, muscular, subcutaneous and intradermic routes. Rabbits, cats, dogs, pigeons and chickens apparently are not susceptible to cranial or muscular inoculation. The presence of the virus in chicken tissues nine days after the cranial inoculation was demonstrated, but tests to verify the maximum persistence of the virus were not performed. It was not possible to demonstrate the virus in guinea pigs and mice of the laboratory colony. Guinea pigs or mice resistant to an infective initial inoculation were not found. Fever and other symptoms developed in almost all of the inoculated animals. Cross immunity and neutralization tests proved that the SP4 strain is serologically similar or closely related to the standard strain of lymphocytic choriomeningitis virus (WE strain, Rivers-Scott).

Personal

Dr. O. de Almeida e Silva has been appointed director of the Department of Hospitals of the city of Rio de Janeiro, succeeding Dr. J. Paes de Carvalho.

Dr. Joaquim Motta has been appointed director of the Department of Public Health of this city, succeeding Dr. R. de Almeida Magalhães.

Dr. William Coolidge, the scientist who introduced improvements in x-ray tubes, recently spent some time in Rio de Janeiro and São Paulo, where he was honored by the National Academy of Medicine, by the Brazilian Academy of Sciences, by the Brazilian Society of Radiology and by the universities of the two cities. Dr. Coolidge delivered several lectures on his research in radiology.

The Society of Forensic Medicine and Criminology of São Paulo awarded the Oscar Freire medal to Dr. Horacio M. Canellas, to Dr. José T. Bittencourt and to Dr. Sylvio Marone for remarkable scientific papers in the field of forensic medicine during 1945.

Deaths

Col. Carlos Eugenio Guimarães of the Brazilian army medical corps, retired, died recently at the age of 64. Dr. Guimarães was a leading surgeon, founder of the Brazilian Red Cross and its president for several years.

Marriages

Edward G. Davis Jr., Richmond, Va., to Miss Doris Davenport of Hampton in Corpus Christi, Texas, September 22.

John Pope Collins to Miss Dorothy Jean Watkins, both of Durham, N. C., at Zanesville, Ohio, January 1.

Joseph Lindsay Cook, Graham, N. C., to Miss Jean Foster Bailey of Greenwood, S. C., December 15.

Gerald Anderson Fostvedt, Harrison, N. J., to Dr. Lucille Marian Radke of Minneapolis, October 20.

Walter W. Hamburger Jr., Chicago, to Miss Ruth C. Kraft of Hackensack, N. J., January 7.

Irwin I. Lubowe, New York, to Miss Ruth C. Katz of Union City, N. J., in Boston, December 22.

Alfred B. Stich to Miss Muriel J. Edelstein, both of Washington, D. C., December 31.

Henry M. Stern to Miss Carol Goodman, both of Wilmington, N. C., January 18.

Leo Wilson to Miss Hilda Loveman, both of New York, December 29.

Correspondence

REACTION FOLLOWING BRONCHOGRAPHY WITH IODIZED OIL

To the Editor:—My comment on the article "Reaction Following Bronchography with Iodized Oil" by Capt. George S. Mahon (The Journal, January 26, p. 194) is prompted by my belief that he has misinterpreted the findings at hand. The proper interpretation of the accident would have prevented this death and should prevent further fatalities.

In his discussion Dr. Mahon correctly disregards the possibility of cocaine poisoning and of allergic shock from cocaine sensitivity because of the time elapsed between the administration of the drug and the onset of the symptoms. The same reasoning should also pertain to the question of a localized lipiodol sensitivity in the bronchi or of allergic shock from the instillation of lipiodol: an allergic reaction severe enough to be fatal would have taken place immediately or shortly after the instillation of the lipiodol. It would have been characterized by generalized edema in most areas of the system as well as in the shock organ itself (Waldbott, G. L.: Allergic Shock: III. From Substances Other Than Pollen and Serum, *Ann. Int. Med.* 7:1308 [April] 1934).

Since the pathologic condition described was typical of death from allergic asthma and since death was due to obstruction of the bronchi by mucous plugs, the preexisting asthma and bronchiectasis should be held solely responsible. There was no indication whatever of "allergic sensitivity to some constituent of lipiodol, probably the iodine"!

In patients displaying a great deal of mucus in the bronchial tree, injections of such additional viscous material as lipiodol into the bronchi not infrequently induce obstruction of the small bronchi followed by atelectasis of lung tissue and pneumonitis or—as in this case—massive collapse of a lung when a main bronchus is involved. It is the result of too much "crowding" in the bronchi.

Two lessons may be learned from the experience of Dr. Mahon's case:

1. If an asthmatic patient has much mucus in the bronchial tree, a lipiodol injection should either be avoided or preceded by bronchoscopic aspiration of mucus.

2. When an accident of this kind occurs, the first measure should be the immediate insertion of a bronchoscope into the bronchi and the aspiration of the obstructing material. This was first proposed by me (Emergency Treatment in Asthma, The Journal, April 30, 1938, p. 1423) as *the* life-saving measure in asthma of extreme severity. In my own experience this has materially reduced the incidence of asthmatic death, regardless of whether the attack originated spontaneously or through the administration of some drug.

George L. Waldbott, M.D., Detroit.

HOSPITAL STAFF MEETING

To the Editor:—The type of medical staff meeting that I describe here has proved of interest to other groups of doctors who have learned about it. After two years of use at Geneva Community Hospital it has proved to be successful beyond expectations. Although no originality is claimed for the idea behind the meeting, I conceived it for the first time for use at Geneva in January 1945.

A subject is selected from a group suggested by the staff, biliary tract disease, for example. This is divided into anatomy of the biliary tract, congenital deviations, etiology and pathology of disorders, medical and surgical diseases with diagnosis and management, one subject being assigned to each staff man until the entire subject is covered. Time is limited to ten minutes. After completion of presentations, questions are accepted from the floor for answering. They are listed by the secretary. Those left unanswered or those provocative of controversy are compiled.

An authority on the subject (most of our guests have been members of the faculties of medical schools in Chicago) is invited to be guest at a subsequent meeting. The questions are sent to him a week in advance. He comes prepared to offer answers or enter into the controversy. Much information is derived by all.

Illness has been about the only reason that has kept staff members or guests away from meetings.

The pleasure of the staff and the amazing attendance records prompt this report, with the idea that other hospitals might like it.

James P. Campbell, M.D., Wheaton, Ill.

OPPORTUNITIES FOR PRACTICE IN CHINA

To the Editor:—I should like, as a medical missionary in China for thirty-eight years—soon to go back—to reinforce the letter of Drs. Hume and Forman published in The Journal, February 2. There are wonderful opportunities in China and the other mission fields for young men and women to put their lives where they will do most good and help to bring in the era of lasting peace. The life is stimulating, developing and deeply rewarding. Especially is this true of medical missionaries. After study of the language, which in the case of Chinese is fascinating in my opinion, the doctor, man or woman, is thrown into a busy hospital work with unlimited opportunities of development along any special line. Especially rewarding is the working with people of another race, getting to know and understand them and helping them to a more abundant life. It isn't always easy—one has to be a pioneer and build, improvise and perfect. But such a life should appeal to those who have a deep faith in God and in men and who want to make their lives count in this troubled world.

Harry B. Taylor, M.D., Anking, China.

MEDICAL NEEDS IN YUGOSLAVIA

To the Editor:—I have been informed that over a month ago the chief delegate of the Yugoslav Red Cross, Lieut. Col. Robert Neubauer, called on you and gave you a true picture about the health conditions existing in Yugoslavia today. According to authentic information there are over a million children afflicted with pulmonary tuberculosis, among whom are more than 12,000 cases of bone tuberculosis. The present relief campaign was organized by Americans under the honorary chairmanship of Mrs. Eleanor Roosevelt especially to ward off the starvation and famine of Yugoslav children. I wish also to inform you that there are more than six million Yugoslavs completely exhausted, undernourished and facing starvation because of widespread devastation and complete destruction of the country by Nazi-fascist invaders.

I am writing to you as an American citizen of Yugoslav descent (from Ljubljana-Slovenia) who knows intimately the country from historical, ethnical, economopolitical and linguistic-cultural points of view. It is imperative for our government to get correct, true and unbiased information about the new Yugoslav Republic if we want to avoid disturbing political storms that may confront us in the near future. A few days ago I received a letter from Dr. Božidar Lavrič, professor of surgery at Ljubljana University, who wrote:

"Our medical institutes need laboratory equipment of all kinds, and surgical instruments used in brain and neurosurgery and modern oral surgery. At present the most urgent need exists for microscopes, analytic apparatus, cameras and projection apparatus employed in teaching the students We would be extremely grateful if we could get a single apparatus for anesthesia with cyclopropane or nitrous oxide In fact, our young medical faculty is the weakest in technical laboratory equipment, we still have enough of our own sanitary material, cotton and gauze and we are getting it also from UNRRA We tried to obtain medical literature from America but we were unsuccessful We need urgently special medical reviews and medical books that will enable us to replace those we lost during five years of occupation and war '

From the foregoing translation of a part of the letter of Dr Božidar Lavric you can easily see how thorough the Nazi-fascist invaders were in destroying universities, libraries and laboratories

Chicago

RESTLESS LEGS

To the Editor —The editorial on "Restless Legs" (THE JOURNAL, Nov 24, 1945, p 875) interested us deeply You refer to a syndrome described by Axel Ekbom in which the most characteristic signs are paresthesias over the inner aspect of the legs which develop only when the legs are still and induce the patient to move the legs to get relief The same syndrome was described by us in the *Confinia Neurologica* **3**:*110, 1940* under the heading "Familiares Auftreten von Pruritus, Urtikaria und parasthetischer Hyperkinese der unteren Extremitaten" We assumed that this syndrome may be due to a heredodegeneration of the nervous system Since then we have observed another family instance in which the patient described his disease in a graphic way as *"fidgets"*

Bureau of Investigation

SOME MISCELLANEOUS MEDICAL FRAUDS

A Variety of Schemes Debarred from the Mails

Fraud orders issued by the Post Office Department have frequently been the subject of extensive articles by the Bureau of Investigation in these pages of THE JOURNAL Following are abstracts of two such orders

Cal-Indo (or Cal-Inda) Company —These were trade styles for a Los Angeles concern *which sold* through the mails something known as 'Calindo [or Calinda] Tablets" The promoters represented that this was a competent, effective and curative treatment for constipation high blood pressure, liver ailments, diabetes, neuritis, arthritis, rheumatism, intestinal disorders and so called heart trouble, regardless of the age and physical condition of the user, *that persons taking these products* would receive benefits identical with, or similar to, those claimed by other *users in* testimonials appearing in the concern's sales literature, that the tablets contain minerals required by the system in the normal functioning of the human body, and that the continued use of the *preparation*, until all symptoms have disappeared, will restore the liver, kidneys, intestines, pancreas and spleen to a state of normal function The *Post Office Department* declared these representations to be false and fraudulent, and cited the concern to show cause why it should not be debarred from the mails One L G Dieker, designated as president of the firm, filed a written reply, denying any violation of the postal laws and any representation that his tablets were an effective treatment for the diseases *mentioned Nevertheless the Post* Office Department was able to cite many testimonials to the effect that the tablets *had been effective* for diabetes, neuritis, arthritis, asthma, high blood pressure, heart and liver troubles and intestinal disorders At the hearing of the case a chemist of the Food and Drug Administration testified for the government that the *Calindo (Calinda) Tablets (pink* coated) contained belladonna ginger, podophyllin and cascarin He testified further that the accompanying brown coated tablets (exact name not reported) contained emodin bearing material licorice, leptandra, podophyllin ginger, possibly anise and acid insoluble material used as a *binder, which was probably* talc A Senior Medical *Officer* of the Food and Drug Administration testified for the government that, among other things the total action of the drugs mentioned would be *that* of any irritant laxative useful only as a means of relieving occasional or temporary constipation, that, scientifically considered, they would not be a *proper treatment* or cure for chronic constipation, and that certain types of this disorder would probably be made worse by this treatment He further declared that the tablets contained no significant amount of minerals and therefore would be of no value in treating any condition resulting from a mineral deficiency Again he showed that there is no *scientific* basis *for* a statement or belief that high blood pressure is in any way caused by constipation or relieved by laxative drugs His testimony included a discussion of the *causes and proper treatment of diabetes*, rheumatism and heart and liver disorders, and showed the futility and even danger in treating such conditions with laxatives As a result of the hearing, L G Dieker, the Cal Indo Company and the Cal Inda Company were on Dec 7, 1944, denied the use of the mails In this connection *it is worth noting that in the Calindo literature there was* the claim "no man will ever know 'What Strange Secret' nature has locked in these wonderful herbs from the far away jungle country" This recalls the fact that in 1931 and for a few years afterward something called "Duryana' and claimed to be based on "jungle fruits" was *being advertised by an L G Dieker of the Duryana Company*, 402 Bradbury Building Los Angeles Earlier in 1931 it was reported that a "Dr Dieker' having the same Los Angeles building and room address as above was agent for a "fruit gland food' known as "Lukutate" No record could be found of Dieker as a Doctor of Medicine or as any *kind of* 'drugless healer" Lukutate, a nostrum from Germany, was dealt with at some length in this department of The Journal Jan 25 1930 page 281 A later name for it was "Dur Inda" a *discussion of which appeared in The Journal April 23, 1932*, page *1493*

Lee Products *—Under this trade style* one Milton L Lieberman sold some fifteen nostrums by mail from his Chicago residence He was said to claim to be a registered pharmacist and to have his own laboratory 'modestly equipped," at his home Because of questionable claims made for three of his products "Anti Gray Hair Vitamin" "Lee s Rheumatic Pills' and "Lee's Special Pills" he was notified *by* the Post Office Department to show cause at a hearing in Washington why his business should not be debarred from the mails as a fraud Among these claims were that the Anti Gray Hair Vitamin, when used as directed, would restore the 'natural youthful color" to gray hair of any person, regardless of age or cause of discoloration, and that such restoration would be accomplished "within 24 to 50 days", that Lee s Rheumatic Pills when taken as directed would *provide* the "desired *relief*' from 'the tortures of pain" incidental to arthritis, neuritis and sciatica, regardless of the cause or duration thereof or the age or condition of the user, *and that Lee's Special Pills*, when used *according to directions*, would give "sure" relief to persons suffering from kidney and bladder ailments Although Lee's attorney asked *the* Post Office *Department for* certain extensions of time, and finally for a disposition of the case by "agreement or stipulation" which was denied neither he nor his client appeared at the hearing in Washington On that occasion a qualified chemist testified for the government that his analysis did not disagree with the *statement of ingredients given* on the label of Anti Gray Hair Vitamin namely that each tablet contained 10 000 micrograms of calcium pantothenate and 333 units of vitamin B1, plus B complex from yeast, that Lee s Rheumatic Pills are actually gelatin capsules each containing a white powder in which were found 7 2 grains of sodium salicylate, 1 13 *grams of* aspirin and 4 5 grains of sodium bicarbonate, whereas Lee's Special Pills were blue coated tablets consisting of potassium nitrate, cascara juniper berries and buchu A Senior Medical Officer of the Food and Drug Administration testified for the government that the chief cause of gray hair is aging processes though it may be caused by debilitating, systemic diseases glandular disorders, heredity or nerve injury resulting from accidents In some cases the grayness may be only temporary and the original color may return especially in cases of younger persons whose health is restored after some sudden or acute condition which caused the gray hair The witness further testified that there is no scientific medical evidence to show that calcium pantothenate, either separately or in combination with the other ingredients of the mixture in question will restore natural color to gray hair He cited the results of a scientific test in which he had participated and in which 27 persons with gray hair working in the same office were given daily dosage of 20 milligrams of calcium pantothenate for a period of six months at the end of which time every one of them still had gray hair Discussing Lee's Rheumatic Pills the witness stated that rheumatism may arise *from many causes* and *take various forms* and that since no single treatment would be adapted to all of these the Lee *nostrum* would be an unscientific treatment for them Lee's Special Pills he showed *to* be equally ineffective in their own field that of kidney and bladder disorders He declared that many serious diseases of these organs, and other *ailments mistaken for them, cannot be cured* by any home treatment, but rather, require scientific study and handling The evidence presented was considered to confirm the charge that of obtaining money through the mails by means of false and fraudulent pretenses, representations and promises and on Dec 1, 1944, a fraud order was issued to debar the Lee *Products from further use of the* mails Meantime, another government agency, the Federal Trade Commission, also had objected to certain unwarranted claims made for "Lee's Periodic Pills" and "Lee's Periodic Capsules" put out for 'feminine hygiene" by Milton L Lieberman trading as Lee Products and as Chemi Culture Laboratories As a *result, the* Commission announced on Dec 5, 1943 that Lieberman had entered into a stipulation *with* the Commission, agreeing to discontinue these misrepresentations The case was briefly reviewed in this department of The Journal Sept 16 *1944* page 189 A later complaint brought by the Commission in September 1944 against Lieberman and his trade *names and involving further* unwarranted advertising representations for his "female weakness' nostrums *has not yet been concluded*

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Drunkenness: Results of Chemical Test of Blood Admissible in Evidence on Question of Intoxication.—The plaintiff sued to recover damages for the death of her husband, which was alleged to have resulted from the defendant's negligent operation of a motor vehicle. From a judgment for the plaintiff, the defendant appealed to the Supreme Court of Oregon.

The defendant was a soldier stationed at Camp White, Oregon. At the trial Captain Porro, a medical officer at the camp hospital, was permitted to testify that he had made a chemical test of the defendant's blood after the accident and that it disclosed a sufficient quantity of alcohol to indicate intoxication. The defendant objected to the admission of such testimony on the ground that the presence of alcohol in the blood stream is no evidence of intoxication. We think, said the court, that, when intoxication is the issue, testimony by a qualified witness as to the result of a blood test has probative value and should be received. Continuing, the court said that the subject of blood and urine tests in this connection had been discussed in numerous published scientific treatises and that there is ample support for the following statement from the exhaustive article "The Medico-Legal Aspects of the Blood Test to Determine Intoxication" by Ladd and Gibson, 24 Iowa L. Rev. 190:

> The blood and urine test to determine intoxication has reached a stage of scientific development and reliability where it may serve a most useful purpose in assisting courts and juries to discover the truth in cases in which intoxication is an issue.

Another objection to the Captain's evidence was that the test offends against the rule that a witness will not be permitted to express an opinion on the merits of a case. The Supreme Court said that an expert witness, testifying as to the result of a blood test, may say that a given quantity of alcohol found in the blood of a particular individual indicates intoxication in a greater or less degree, but, since his testimony is based solely on the result of the blood test, he may not, of course, give his opinion that the individual in question was in fact intoxicated. In this particular, the testimony of Captain Porro was not objectionable. Furthermore, the competency of such testimony is not at all impaired because some persons yield more readily than others to the deleterious effects of intoxicants. That fact, concluded the court, may lessen the weight of the testimony, but it will not exclude it.

The judgment in favor of the plaintiff was reversed, however, because of the failure of the evidence to show that the blood which Captain Porro examined was in fact the blood of the defendant.—*Natwick v. Moyer et ux 163 P. (2d) 936 (Ore., 1945).*

Medical Practice Acts: Osteopathic School Granted Discretion in Admission Requirements.—Plaintiff, in the name of the People of the State of Illinois, filed a mandamus action to compel the defendant, Department of Registration and Education, to permit her to take an examination for a license to practice osteopathy. From a judgment denying the requested relief, the plaintiff appealed to the appellate court of Illinois.

Section 5, paragraph 2(b) of the medical practice act provides, in reference to the educational standards set up for osteopaths and other limited practitioners,

> . . . that such . . . college . . . at the time of his graduation required as a prerequisite to admission thereto a *four years' course* of instruction in a high school, and as a prerequisite to graduation therefrom a *four years' course* of instruction . . . of not less than *eight* months each, . . . the time elapsing between the beginning of the first year and ending of the fourth year . . . having been not less than thirty-six (36) months, . . . such high school and such . . . college . . . having been reputable and in good standing in the judgment of the department.

The defendant denied that the high school which the plaintiff attended was in good standing.

The plaintiff testified that, in order to qualify for admission to the Chicago College of Osteopathy, from which she graduated in June 1942, she had studied in a state chartered adult high school and under private tutelage to gain fifteen high school credits. In 1937 she took the University of Illinois examination in high school subjects and was admitted to the college in September of that year. When admitted, the results of the examination on only 12½ credits were known and to that extent she passed. Later she learned that she had passed only 2 of the remaining 2½ credits, having failed in physiography. When she was admitted to the college, the college assumed that she had passed the 15 credits, but, on learning of the final results of the examination, it consented to her continued study on condition that she make up the deficiency by examination. She failed in the physiography examination three times and then, with the consent of the college, abandoned that subject, studied organic chemistry at Lewis Institute in Chicago, passed the examination in that subject and subsequently graduated from the college.

In the oral argument before the appellate court, the defendant admitted that four years of high school was not required; it contended however that, since the plaintiff entered the college with less than 15 credits, the equivalent of a four years' high school, she was not qualified to take the examination for a license to practice osteopathy. The question, said the court, is whether the plaintiff should be disqualified because, when admitted to the college, she was deficient in credits.

The court noted that the medical practice act does not require 15 credits. There is no requirement under its provisions that plaintiff must have had a high school education. The requirement is that the college, at the time of the plaintiff's graduation, should require, as a prerequisite to admission, "a four years' course." It is a matter of common knowledge, said the court, that colleges and universities exercise a certain discretion in their admission requirements. Moreover, the tendency in judging educational attainments is strongly toward considerations of ability rather than records or credits. We believe, continued the court, that the discretion of the college extended to permitting the plaintiff to continue study on the condition that she make up ½ credit. Under the circumstances of this case, the court concluded, we think a grave injustice will be done if plaintiff is denied the writ of mandamus. Accordingly the judgment of the trial court was reversed and the cause was remanded with directions to enter a judgment for the plaintiff.—*People ex rel. Harmon v. Thompson, Director of Registration and Education, 63 N. E. (2d) 624 (Ill., 1945).*

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in The Journal, Feb. 23, page 531.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Part III. Various Centers, March. Exec. Sec., Mr. E. S. Elwood, 225 S. Fifteenth St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Oral.* New York, Oct. 9-14. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York 22.

American Board of Internal Medicine: *Oral.* Philadelphia, May 9-11. Final date for filing application is March 15. San Francisco, June 27-29. Final date for filing application is April 15. Asst. Sec., Dr. W. A. Werrell, 1 W. Main St., Madison 3, Wis.

American Board of Ophthalmology: Chicago, Oct. 9-12. Sec., Dr. S. Judd Beach, 56 Ivie Rd., Cape Cottage, Me.

American Board of Orthopedic Surgery: *Part I.* New Orleans, May 3-4, San Francisco and St. Louis, May 10-11 and Philadelphia, May 17-18. Final date for filing application is March 10. Sec., Dr. G. A. Caldwell, 3503 Prytania St., New Orleans 15.

American Board of Otolaryngology: Chicago, May 22-25. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City, Ia.

American Board of Pediatrics: *Written.* Locally, March 22. *Oral.* Cleveland, April 27-28 and San Francisco, July 1-5. Sec., Dr. Lee F. Hill, 3309 Forest Ave., Des Moines, Ia.

American Board of Radiology: Chicago, Nov. 27 to Dec. 1. Final date for filing application is Sept. 1. Sec., Dr. B. R. Kirklin, Mayo Clinic, Rochester, Minn.

American Board of Surgery: *Written. Part I.* Various centers, October. Final date for filing application is July 1. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia 2.

American Board of Urology: *Oral.* Chicago, February 1947. Final date for filing application is Nov. 15. Sec., Dr Gilbert J. Thomas, 1409 Willow St., Minneapolis 4.

POSTGRADUATE CONTINUATION COURSES FOR VETERAN AND CIVILIAN PHYSICIANS

(Supplementary to listing published Dec. 8, 1945, Vol. 129, pp. 1046-1059).

Institution	Title of Course	Schedule of Course	Registration Fee and/or Tuition
	ALLERGY		
University of Colorado School of Medicine, 4200 East Ninth Ave., Denver	Skin and Allergy	Arranged, 3 days	$20
Cook County Graduate School of Medicine, 427 S. Honore St., Chicago	*Personal Course in Allergy and Related Conditions*	*April 3-June 5, 1946, once weekly*	125
University of Michigan Medical School, 1313 East Ann St., Ann Arbor, Mich.	Allergy	May 13-18, 1946	Not stated
	ANATOMY		
Cook County Graduate School of Medicine, 427 S. Honore St., Chicago	Surgical Anatomy on the Cadaver	April 3, 1946, 10 weeks once weekly	125
	ANESTHESIOLOGY		
Ohio State University College of Medicine, 11th and Neil Aves., Columbus, Ohio At: University Hospital	*Anesthesiology*	*Arranged, at least 3 months*	
	ARTHRITIS		
University of Colorado School of Medicine, 4200 East Ninth Ave., Denver	Arthritides including Rheumatic Fever	Arranged, 3 days	20
	CHEST DISEASES		
University of Colorado School of Medicine, 4200 East Ninth Ave., Denver At National Jewish Hospital	Diseases of the Chest	Arranged, 3 days	20
Cook County Graduate School of Medicine, 427 S. Honore St., Chicago	Technic of Physical Examination and Diagnosis of Chest	April 5, 1946, 8 weeks once weekly	65
New York *State Dept. of Health, Alfred E. Smith State Office* Bldg., Albany, N. Y. At Various state tuberculosis hospitals	Course of *Instruction in Pul*monary Disease and Tuberculosis	Arranged, 3 to 12 months	
	CARDIOVASCULAR DISEASE		
University of Colorado School of Medicine, 4200 East Ninth Ave., Denver	Cardiovascular Diseases (Including Peripheral Vascular Diseases)	Arranged, 4 days	25
	DIABETES		
Harvard University Medical School Courses for Graduates, 25 Shattuck St., Boston	Diabetes Mellitus in Relation to General Medicine	Scheduled April 1-3, 1946, postponed to April 22-24, 1946	20
	ENDOCRINOLOGY		
University of Colorado School of Medicine, 4200 East Ninth Ave., Denver	*Endocrine Diseases*	*Arranged, 2 days*	15
	FRACTURES		
Cook County Graduate School of Medicine, 427 S. Honore St., Chicago	Special Course in Fractures	March 20, 1946, 10 weeks once weekly	125
	GASTROENTEROLOGY		
University of Colorado School of Medicine, 4200 East Ninth Ave., Denver	Gastro Intestinal Diseases	Arranged, 3 days	20
University of Michigan Medical School, 1313 East Ann St., Ann Arbor, Mich.	Gastroenterology	June 17-21, 1946	Not stated
	HEMATOLOGY		
University of Colorado School of Medicine, 4200 East Ninth Ave., Denver	Blood Diseases	Arranged, 3 days	20
Cook County Graduate School of Medicine, 427 S. Honore St., Chicago	Course in Hematology	April 3, 1946, 10 weeks once weekly	100
University of Michigan Medical School, 1313 East Ann St., Ann Arbor, Mich.	Diseases of the Blood	June 3-8, 1946	Not stated
	INDUSTRIAL HEALTH		
Wayne University School of Occupational *Health, 1516* St. Antoine St., Detroit	*Occupational Health and* Medicine	March 4, 1946, 12 weeks (postponed because of labor conditions)	Not stated
	MEDICINE, GENERAL		
Cook County Graduate School of Medicine, 427 S. Honore St., Chicago	Course in Heart Disease and Electrocardiography	April 5-June 19, 1946, 10 weeks once weekly	125
University of Kansas School of Medicine, 39th St. and Rainbow Blvd., Kansas City, Kan.	Internal Medicine, Psychiatry, Dermatology	March 25-29, 1946	Not stated
Kentucky Medical Association, Louisville, Ky. At Louisville General Hospital	Refresher Course in Internal Medicine	6 weeks, given continuously	None
University of Maryland School of Medicine, Lombard and Green Sts., Baltimore	General Medicine, including Medicine, Surgery, Pediatrics, Obstetrics and Gynecology	April 15-June 8, 1946, 8 weeks	100
Boston University School of Medicine, 80 E. Concord St., Boston	Internal Medicine	March 15, 1946, *6 months*	375
Beth Israel Hospital, *330 Brookline* Ave., Boston	Postgraduate Course in Internal Medicine	1 academic year	Not stated

Institution	Title of Course	Schedule of Course	Registration Fee and/or Tuition
	MEDICINE, GENERAL—Continued		
St. Louis University School of Medicine, 1402 S. Grand Blvd., St. Louis	Aspects of the Medical and Surgical Specialties in General practice	May 13-June 8, 1946	$62.50 G. I. Bill of Rights
	General Refresher Courses in Medicine and Surgery	March 15-May 11, 1946	Each course 125
Cornell University Medical College, 1300 York Ave., New York At: Bellevue Hospital	Graduate Course in Internal Medicine	April 1, 1946	6 months 250 2 weeks 50
University of Pittsburgh School of Medicine, Bigelow Blvd., Pittsburgh	Refresher Course for General Practitioners	8 weeks tentatively scheduled for April 1, 1946	150
	NEUROLOGY and PSYCHIATRY		
Cook County Graduate School of Medicine, 427 S. Honore St., Chicago	Neurology for the General Practitioner	April 3, 1946, 10 weeks once weekly	80
University of Colorado School of Medicine, 4200 East Ninth Ave., Denver	Neurology and Psychiatry	Arranged, 3 days	20
	OBSTETRICS and GYNECOLOGY		
University of Colorado School of Medicine, 4200 East Ninth Ave., Denver	Gynecology	Arranged, 1½ days	15
	Obstetrics	Arranged, 2½ days	20
Cook County Graduate School of Medicine, 427 S. Honore St., Chicago	Practical and Didactic Course in Office Gynecology	March 13, May 8, July 10, Aug. 28, Oct. 9, Nov. 20, 4 weeks once weekly	80
	Personal Course in Gynecological Surgery	March 14, May 9, July 11, Aug. 29, Oct. 10, Nov. 21, 4 weeks once weekly	80
University of Kansas School of Medicine, 39th St. and Rainbow Blvd., Kansas City, Kan.	Obstetrics and Gynecology	June 17-21, 1946	Not stated
Boston University School of Medicine, 80 E. Concord St., Boston	Obstetrics and Gynecology	March 15, 1946, 6 months	375
St. Louis University School of Medicine, 1402 S. Grand Blvd., St. Louis	Gynecology and Obstetrics	April 15-May 11, 1946 4 weeks	62.50 G. I. Bill of Rights
	OPHTHALMOLOGY		
The Ophthalmalogical Study Council, 520 Commonwealth Ave., Boston	Intensive Course on the Basic Subjects of Ophthalmology	April 1-June 1, 1946	2 months 200 1 month 110
Washington University School of Medicine, Euclid Ave. and Kingshighway, St. Louis	Refresher Course in Ophthalmology	June 3-29, 1946	200
	ORTHOPEDIC SURGERY		
University of Colorado School of Medicine, 4200 East Ninth Ave., Denver	Orthopedics	Arranged, 3 days	20
Boston University School of Medicine, 80 E. Concord St., Boston	Orthopedic Surgery	March 15, 1946, 6 months	375
	OTOLOGY		
Harvard Medical School Courses for Graduates, 25 Shattuck St., Boston	All Day Course in Otology	April 1-30, 1946	185
	OTORHINOLARYNGOLOGY		
University of Kansas School of Medicine, 39th St. and Rainbow Blvd., Kansas City, Kan.	Eye, Ear, Nose and Throat	April 15-19, 1946	Not stated
Boston University School of Medicine, 80 E. Concord St., Boston	Ear, Nose and Throat	March 15, 1946, 6 months	375
Manhattan General Hospital, New York City	Clinical and Laboratory Course in Rhinoplasty	March 18-April 18, 1946	Not stated
	PEDIATRICS		
University of Colorado School of Medicine, 4200 East Ninth Ave., Denver	Pediatrics	Arranged, 3 days	20
St. Louis University School of Medicine, 1402 S. Grand Blvd., St. Louis	Pediatrics	May 13-June 8, 1946	62.50 G. I. Bill of Rights

University of Colorado School of Medicine, 4200 East Ninth Ave., Denver	Communicable Diseases, Venereal Disease	Arranged, 4 days	25

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1936 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

*Transient 0 Diastolic Brachial Pressure (Indirect) Associated with Normal or Elevated Popliteal Pressure, Tachycardia and Nervous Tension. M. Wilburne.—p. 381.
New Form of Generalized Arterial Disease in Negroes: Report of 2 Cases. W. M. Yater and J. T. Roberts.—p. 390.
Evaluation of Vascular Reserve in Peripheral Vascular Disease. G. Saland and B. Calef.—p. 398.

Traumatic Rupture of Normal Aorta.—McDonald and Campbell report histories of 2 young men aged 32 and 24 respectively in whom the normal aorta had ruptured. Both ruptures occurred as the result of an automobile accident. An element produced by torsion of the head and trunk was probably an important factor in rupturing the vessel. The site of the rupture was distal to the emergence of the major branches of the aorta, which is the relatively mobile point of the thoracic aorta. A sudden blow displacing the thoracic structures might cause a rupture in this mobile section either by direct or by contrecoup force. In both patients there was a fracture of a few ribs but displacement of only one, on the right side. In the absence of abnormalities on macroscopic and microscopic study of the aorta it is clear that complete transection of all the coats of the aorta owing to trauma in these 2 young adults is in striking contrast to spontaneous rupture of the aorta resulting from a process described by Erdheim as medionecrosis aortae idiopathica. Measures directed at combating shock and supporting the circulation are fruitless.

Transient 0 Diastolic Brachial Pressure.—Wilburne observed in the course of routine examinations of men for induction into the armed forces a hitherto undescribed cardiovascular syndrome in examinees exhibiting great nervous tension. In addition to the nervous element the syndrome was characterized by transient 0 diastolic brachial pressure (indirect method), normal or elevated popliteal pressure and tachycardia. At first it was thought that perhaps these were cases of functional aortic insufficiency; consequently blood pressure readings were recorded in the lower extremities. The brachial systolic pressure associated with the 0 diastolic tension ranged from 118 to 250 mm. of mercury and averaged 159.1. The popliteal systolic and diastolic pressures in the prone position averaged 202.3 and 101.9 respectively. In the standing position the popliteal pressures were considerably higher. The heart rate ranged from 90 to 168 and averaged 127.4. Following rest periods varying between five and ninety minutes the diastolic pressure rose to values ranging from 60 to 112, exhibiting an average level of 75.2. The brachial systolic pressure revealed an average fall of 11 from the initial levels. The popliteal systolic pressure in the prone posture exhibited an average drop of 12.5. The popliteal diastolic pressure showed an average drop of 7.1. (The popliteal blood pressure in the standing position exhibited a corresponding reduction.) After resting the heart rate ranged from 76 to 148 and averaged 104.7, representing a fall of 22.7 beats per minute. These cases do not represent functional aortic insufficiency, because an aortic diastolic murmur was absent and a brachial diastolic pressure of 0 is generally not encountered in functional aortic insufficiency. Evidence of left ventricular dilatation was not found, and the diastolic pressure in the lower extremities did not show a corresponding change.

Tissue Changes Induced by Senecio Riddellii. I. Rosenfeld and O. A. Beath.—p. 407.

Tissue Changes in Protein Deprivation.—Fallas Diaz and Nettleship did postmortem examinations on children who died of dietary protein deficiency. There was a moderate to severe emaciation, with universal edema and anemia. Microscopically there is loss of cell cytoplasm and nuclear condensation with a noninflammatory edema, intracellular and interstitial. There is a loss of cells from the adrenal medulla with fibrosis, and cloudy swelling of the kidney with tubular cell loss. There is severe, widespread, irregular fatty infiltrations of the liver with, in some instances, flecks of acute necrosis.

Vitamin C Nutrition of Rural Population in Tennessee.—Youmans and his associates assessed the nutrition of a rural population in Middle Tennessee with respect to vitamin C by a study of the diet, the medical history and physical examination and determination of the concentration of vitamin C in the blood. Records of the dietary intake suggest that many people apparently can subsist on amounts of vitamin C at present believed to be inadequate without developing symptoms of ascorbic acid deficiency. The history and examination did not disclose scurvy and only infrequently revealed clinical evidence of a deficiency. Gingivitis, perhaps the best sign of minor deficiency, was found in a considerable proportion of the adults, and while statistical analysis of the data suggests the influence of other factors, there is also an indication of relation to the lack of vitamin C. X-ray examinations revealed only 1 instance of bone changes indicative of mild scurvy. With the paucity of reliable physical evidence of deficiency of vitamin C, the evaluation of the nutrition of the population in respect to this factor rests mainly on the concentration of vitamin C in the blood. Every subject tested showed some vitamin C in the blood, and only 10 had a concentration less than 0.1 mg. per hundred cubic centimeters. Whether a conclusion about the vitamin C nutrition is to be based on the evidence obtained will depend on the concentration which is designated as "abnormally low" and the significance to be attached to the concentration of ascorbic acid in the blood as an index of this nutrition. If it is assumed that concentrations below 0.3 mg. per hundred cubic centimeters represent a subnormal state of vitamin C nutrition, then by this standard about 92 subjects (8.6 per cent) of those examined were deficient.

Azotemia in Typhus.—Yeomans and his associates report observations made in 1943 and 1944. The data were obtained from 64 patients in the United States of America Typhus Commission ward and 14 patients in the general wards of the Cairo Fever Hospital. Azotemia in epidemic louse borne typhus was found to occur frequently (in more than half of the cases), as indicated by elevated concentrations of blood nonprotein nitrogen, urea nitrogen and creatinine. The correlation between clinical severity and azotemia was striking. Elevated concentrations of blood nonprotein nitrogen were found in every fatal case in which the blood was examined. Azotemia appeared to be closely associated with excessive destruction of body protein and increased nitrogen excretion, with dehydration and a reduced output of urine in the presence of normal kidney function, and in severe cases with a sudden rapid fall in blood pressure associated with evidences of renal insufficiency. The appearance of renal insufficiency as a complicating condition in the disease was in nearly every instance the earliest indication that the patient's course would be severe or would end fatally.

Filariasis in Solders Evacuated from the South Pacific.—Soldiers, sailors and marines have been evacuated to the continental United States from various islands in the South Pacific Area because of suspected filariasis. Goodman and his co-workers report observations on 145 of these men studied at Harmon General Hospital. Signs and symptoms suggestive of filariasis (including lymphadenopathy, lymphangitis, scrotal edema, funiculitis, orchitis and varicocele) appeared on the average after about thirteen months' residence in an endemic area. The symptoms were mild, and only 6 patients experienced bouts of acute lymphangitis during the period of study in the United States. Elephantiasis or chyluria was not encountered. Microfilariae were demonstrated in the blood on one occasion in each of 4 patients (in 2 of these at oversea hospitals). Microscopic examination of excised lymph nodes in 19 cases showed only a nonspecific inflammatory response. Adult worms or remains of worms were not seen. Direct intracutaneous tests using antigens of Dirofilaria immitis and Setaria equina in 1:8,000 dilution gave positive responses in 54 per cent of cases, as compared with 6 per cent in control subjects. Of 75 patients tested with a 1:2,000 dilution of Litomosoides carinii, 46 per cent gave positive reactions. Positive complement fixation tests were found in 95 of 143 patients studied. However, the complement fixation technic used cannot be considered wholly specific, since 16 to 25 per cent of normal control subjects gave positive tests. There was agreement between the results of the complement fixation tests and the direct intracutaneous tests with S. equina and D. immitis in 66 and 71 per cent of patients respectively. Therapy included a liberal diet, "reconditioning" by means of gradually increasing activity and psychotherapy to allay fears as to possible future complications of the disease. The outlook for the men is considered good because of the relatively short residence in the endemic area and the slight degree of infection.

Benadryl in Urticaria.—Benadryl (beta dimethylaminoethyl benzhydryl ether hydrochloride) is a member of a new group of pharmacologically active antihistamine drugs. Curtis and Owens administered it in amounts of 50 to 100 mg. orally one to five times daily to a diverse group of 18 patients with both acute and chronic urticaria. Eleven patients experienced prompt relief of symptoms as long as the drug was taken. Three had definite and real improvement, and many of the wheals which did appear were not pruritic. Four patients were not benefited. The drug has a wide margin of safety. The only toxic manifestations noted were drowsiness and muscular aching (2 cases), dizziness, weakness and vertigo (1 case). Cumulative toxic symptoms were not noted in patients who ingested the drug as long as six or seven months. All toxic symptoms promptly disappeared when the drug was discontinued. The effect is palliative, and in many patients the urticaria recurred when the administration of the drug was discontinued. Since an antihistamine drug seems to be effective in controlling urticaria, it may be assumed that this is further indirect evidence that histamine is a factor in the production of urticaria.

Benadryl for Urticaria and Related Dermatoses.—Shaffer and his co-workers describe 8 cases of urticaria in 7 of which benadryl controlled the pruritus and caused the involution of the urticarial lesions in a fairly short period. The authors suggest that it may prove effective in the palliative relief of urticaria. In acute cases such palliation may be all that is required for their management. In cases of chronic urticaria it might offer valuable relief until investigation reveals the cause and adequate control measures can be carried out. Compared to the neurovascular stimulating action of epinephrine and ephedrine, benadryl apparently does not produce untoward effects, especially on the blood pressure, and in some instances it had a sedative action. Two cases of neurodermatitis, 1 of dyshidrotic eczema, 1 of atopic eczema and 1 of chronic lichen urticatus are hardly sufficient to appraise the value of benadryl for these diseases. However, the limited experience would suggest that it is not of value for neurodermatitis or dyshidrotic eczema. Results obtained by its use for atopic eczema and lichen urticatus warrant further trial.

Senile Hyaline Scleral Plaques.—Roper describes 5 cases of senile hyaline scleral plaques; 2 of the patients were 72, 1 was 78 and the other 2 were over 80 years of age. Patients are frequently not aware of the presence of the plaques. Advanced age is largely responsible for predisposition to the condition, since in the aged dehydration and progressive sclerosis of the connective tissue of the entire body, as well as of the external tunic of the eye, occur. It is probably the result of a local nutritional disturbance, which in turn is due to arteriosclerotic changes. The fact that this unusual degenerative condition of the sclera has a predilection for the area lying in front of the insertions of the rectus muscles suggests that the changes occur not only because of local circulatory disturbances but because of the constant stress and strain on the sclera fibers, which are in such close proximity to the insertions of the rectus muscles. The plaques are situated about 3 mm. from the limbus and 1.5 to 2 mm. anterior to the insertions of the rectus muscles. They are generally rectangular, but occasionally only a rounded or oval patch situated opposite either end of the insertion of a rectus muscle is observed. Microscopic studies have shown that in place of normal sclera there remain some cellular and nuclear fragments and large masses of hyalin. There is general atrophy of the overlying conjunctiva and episclera. A condition without real resemblance, but which has been confused with it, is scleromalacia perforans. The two conditions are alike only in their chronicity and in the fact that they affect the sclera predominantly. Scleromalacia perforans is primarily necrotic in origin, whereas senile hyaline sclera plaques are primarily degenerative in character.

Methyl Testosterone Linguets in Post-Traumatic Simmonds' Disease.—Lisser and Curtis report that a man in 1935, at the age of 20, sustained multiple fractures of the skull in a motorcycle accident. After the injury there were noted polydipsia and polyuria. In the first two months there was a loss of 33 pounds (15 Kg.). During the succeeding eighteen months there was progressive loss of facial and body hair, loss of libido and potentia and increasing fatigability, and the skin acquired a fawn color. There also had been a considerable decrease in mental acuity, with the concomitant development of phobias. The endocrinopathy was diagnosed as "post-traumatic Simmonds' disease" or panhypopituitarism. From 1936 to 1938 the patient received various pituitary extracts, with little if any improvement. In 1942 the patient began to have attacks of pain in the chest and back and hematuria associated with nausea and vomiting. Injections of gonadotropin were started and continued for about ten months. The patient believed that this medication increased his strength and stopped his pain, nausea and vomiting and possibly increased the growth of general body hair. Physical examination did not show special change. Methyl testosterone linguets were now prescribed in a dosage of 20 mg. daily for ten weeks, then 15 mg. daily for six weeks, and 5 mg. daily from Nov. 9, 1944. The latter dose proved insufficient and was increased to 10 mg. daily on Feb. 1, 1945. During the period of testosterone therapy, growth of pubic hair, beard and general body hair occurred. Libido has returned to normal. Erections occur often, the patient has married, and marital relations are satisfactory. He is now working from ten to fourteen hours a day. His physical strength is now much greater, and there has been an increase of 9.5 Kg. in weight.

Six months after testosterone therapy was instituted the basal metabolic rate had risen from minus 28 per cent to plus 2 per cent and the serum cholesterol had dropped from 278 mg. per hundred cubic centimeters to a normal value of 170 mg.

Spasm of Internal Carotid Artery.—Ecker reports 4 cases of dysfunction of the brain due to relatively mild trauma of the internal carotid artery. The first 3 were cases of penetrating wounds of the neck without laceration or thrombosis of the artery or any evidence of direct head injury. The fourth case was a blunt head injury with fracture of the skull and postmortem evidence of brain swelling and ischemic necrosis of the wall of the internal carotid artery. The common denominator in all 4 cases was the application of force to the carotid artery, resulting in spasm of this vessel Within ten minutes there resulted dysfunction of the cerebral hemisphere on the same side, which persisted for a period varying with the degree of anoxemia produced There was swelling of the brain, which probably reached its maximum in twenty-four hours and lasted at least three days. This brain swelling may be due in part to a vasoparalysis of the central nervous system, which in turn may be closely associated with narrowing of the cerebral arteries Dilatation of the cerebral ventricles, especially on the same side, may be a permanent residuum. The syndrome of spasm of the internal carotid artery consists of (1) dysfunction of a cerebral hemisphere, (2) brain swelling in the acute stage, (3) internal hydrocephalus in a late stage and (4) narrowing of the cerebral arteries.

Nutritional Defects Among Vermont Children.—Pierce and his associates made a survey of the nutritive status of 386 Vermont school children selected to represent rural and urban groups of various ages and economic levels A review of the food intake showed the greatest defect to be the low intake of fruits and vegetables. Blood studies revealed that 25 per cent of a group of 176 children had plasma vitamin C levels below 0.6 mg. per hundred cubic centimeters, and on physical inspection 40 per cent of the entire series had inflammation of the gums of varying intensity. Severe forms of spongy, bleeding gums were found in only a small percentage of the children Six per cent of 170 children had low hemoglobin values suggestive of a mild anemia Urban children had higher hemoglobin levels than did rural children. Skeletal changes usually associated with rickets were found in about 85 per cent of the children. Signs associated with a shortage of riboflavin were found in a small percentage of the children, but they could not be accepted as definitely indicating any serious deficiency of this vitamin. Some degree of folliculosis, at least of the outer aspect of the arm, was found in 40 per cent of the children, and 5 of these subjects had a generalized folliculosis Mild cases of follicular conjunctivitis were frequent. Premature loss of the teeth and dental caries were found to be extremely prevalent

Profenil—New Antispasmodic Preliminary Report S Weiss—p 436

New Treatment of Amebiasis.—Sokoloff found that lactic acid, even in a weak solution of 1:1,000, impedes the multiplication of protozoa, including amebas. Since ingested lactic acid is actively absorbed in the small intestine and therefore is of little use in the treatment of infections of the large intestine, a special anhydrous form of lactic acid, trilactic, was developed Trilactic dissolves in water slowly and for this reason reaches the colon and cecum without being affected greatly by the gastric juice. Research has demonstrated that trilactic has a therapeutic effect in animals infected with pathogenic bacteria Rats infected with Endameba histolytica were submitted to trilactic therapy. Although they had only a mild form of amebiasis, their stools showed presence of trophozoites and cysts. These disappeared after seven days of treatment with trilactic The animals seemed to have been completely cured During the last five years trilactic has been tested on a number of patients with amebic infection. In many instances they received the trilactic treatment after emetine had failed to eliminate completely the pathogenic ameba, or when the patient had experienced a toxic reaction from this drug. In a few instances trilactic was administered after protracted iodine therapy when stools still showed presence of the cysts Such combined therapy showed the most satisfactory results not only in the complete elimination of the ameba but also in the prompt restoration of the normal bowel movement Sixty-two patients affected with acute and chronic amebic infections have been treated with the anhydrous form of lactic acid known as trilactic. Complete recovery was obtained in 36, improvement in 15 and negative results in 11 patients.

Pneumonoconiosis in Radiator and Boiler Finishers.—Dunner and his associates found that 10 of 13 men who were radiator and boiler finishers showed changes in their chest roentgenograms. The men engaged in this work inhale a great quantity of dust. The dust consists mainly of silica from the sand, iron derived from the boilers and radiators, and carbon from the burnt oil. The roentgenologic aspects are of greatest importance for diagnosis. They consist of a fine mottling, especially noticeable in the mid and lower zones of the lung. Fibrosis, such as occurs in boiler scalers and graphite workers, has not been encountered. Eleven of the 13 men have been coughing or spitting for years and 3 of them have complained of shortness of breath, but 11 have felt fit for work. Two of the 13 men felt ill and unfit for the job. One of these ceased work as a finisher. The chest roentgenogram of this man shows rather dense mottling in the lung. The second patient—56 years of age—feels unfit after having worked in the department for thirty-six years, but the roentgenogram of his chest does not reveal evidence of occupational disease. His condition appears to be attributable to emphysema and premature senility. Whether the appearances in the lung are due only to the deposits of dust or whether there are also reactions of the lung tissue can be decided only by postmortem examination or by experimental work on animals. If the condition proves to be a form of silicosis, then, in the event of disability, these men would be entitled to compensation. In any event, measures of prevention should be instituted, and regular x-ray examination is desirable.

Prevention of Homologous Serum Jaundice.—Loutit and Maunsell say that homologous serum jaundice occurs from 40 to 160 days after the introduction of foreign homologous serum into a recipient. This introduction may be accidental, as during routine venipuncture with syringe and needle for blood samples for blood sugar determinations or routine intravenous injections (e. g., arsphenamine, pentothal), called "syringe jaundice." Traces of foreign blood are believed to have been left in the syringe and, through failure to clean and sterilize the syringe, this foreign serum gained access to the subject's circulation. The introduction of foreign serum may be deliberate, such as in serum or plasma transfusion, prophylactic injections of measles and mumps convalescent serum or normal adult serum and yellow fever vaccination in which human serum is the suspension medium for the killed virus. In the accidental variety of serum jaundice adequate cleaning and sterilization of syringes and needles has been shown to reduce the incidence of postarsphenamine jaundice practically to zero. When the introduction of serum is deliberate, prevention of homologous serum jaundice is much more difficult. The yellow fever vaccine problem was solved only by giving up the use of serum as a suspension medium. The authors direct attention to the good results obtained by MacCallum and Bauer but suggest that their good results may have been due not to apparently healthy donors but to using unpooled serums. Homologous serum jaundice often follows transfusion of serum or plasma. It appears to be uncommon after transfusion of whole blood. The authors therefore decided to investigate the results of introduction of single serums into a number of recipients and to compare the incidence of jaundice with that in a series of cases in which only blood transfusion had been given. Each of 99 individual serums was injected into an average of 6 normal recipients. Homologous serum jaundice was not detected within 150 days. Frank homologous serum jaundice did not occur in a selected series of 213 blood transfusions. Two possible cases of homologous serum jaundice following blood transfusion alone are recorded. Since these experiments with individual serums suggest that they are as safe as individual bloods, it is recommended that individual serums should be used for therapeutic and prophylactic purposes.

Cultivation of Tsutsugamushi Rickettsia in Rodents.—Fulton and Joyner describe a method of adapting Rickettsia tsutsugamushi to grow in the lungs of mice. Still better yields were obtained by passing the mouse lung adapted strain into the lungs of cotton rats. A vaccine prepared from cotton rat lung suspension protected mice subsequently infected with living R. tsutsugamushi. The best protection was obtained when the mice were vaccinated intraperitoneally and infected by the same route, but some protection could also be demonstrated when the mice were vaccinated subcutaneously and infected by the intraperitoneal route. Without a field trial it is impossible to decide whether or not this vaccine will be of value in man.

Poisoning by Barium Carbonate.—Morton describes two attacks of food poisoning which involved 85 British soldiers in an area of the Persia/Iraq command and were subsequently shown to be due to barium carbonate. In the first outbreak 13 men were admitted to a military hospital with acute gastroenteritis. The men were taken ill one hour after their evening meal, which consisted of meat and vegetables followed by marmalade tart. Three sergeants who had refused the tart were not affected. Five soldiers who had eaten some of the remaining tart but no other part of the meal also became ill and were admitted to the hospital. Before laboratory findings regarding the first outbreak, other than those excluding arsenic as the poison, were available 71 men in the same unit were taken ill two hours after a meal. Of these, 31 were admitted to the hospital and 40 were treated in the unit. The meal consisted of meat, vegetables and treacle tart. Again only the men who had eaten the tart were affected. A chemical analysis of the pastry of the tarts revealed large quantities of barium carbonate. At the supply depot a sack containing 4 pounds of barium carbonate for use as rat poison had been placed in error in the flour store, filled with ordinary flour and issued to the unit. This flour had been used only for the pastry of the tarts. The symptoms consisted of an initial phase of gastroenteritis with tingling sensations of the face and neck, followed by loss of tendon reflexes, disordered action of the heart and muscle paralysis. In a few severe cases paralysis spread and became generalized, in 1 case leading to almost complete respiratory paralysis. Recovery was rapid, and there were no deaths.

Thiouracil in Pregnancy.—Davis and Forbes report that a woman aged 21 who was admitted to a hospital in April 1944 with the symptoms of mild thyrotoxicosis and who had been delivered of a healthy child six months previously was given thiouracil 600 mg. daily. This treatment was well tolerated and gave considerable symptomatic benefit. The patient was discharged from the hospital on July 6, 1944 and instructed to take thiouracil 200 mg. daily. Thereafter she was seen at short intervals, and on each occasion her general condition was excellent. When seen in November she believed that she had recently become pregnant. Thiouracil was therefore reduced to 200 mg. on alternate days. A month later her condition was still satisfactory and the diagnosis of pregnancy confirmed. She continued to take thiouracil as directed and remained in good health until March 18, when she complained of headache, which persisted during the next two days, and on March 20 she suddenly became cyanosed, collapsed and died. She was then six months pregnant. Necropsy studies were made on the mother and the fetus. The cause of the mother's death was uncertain. The thyroid of the fetus was enlarged and hyperplastic, as compared with a presumably normal gland from a premature infant, and showed histologic evidence of considerable functional activity. It resembled the gland of an adult receiving too much thiouracil. Administration of thiouracil to pregnant women, and probably to nursing mothers, demands caution.

Cervical Tumor Simulating Amyotrophic Lateral Sclerosis.—De Lehoczky and Piri report the case of a neurogenous, epidural and paravertebral tumor is a boy aged 16. Two years prior to admission the boy had developed pain in the neck and later pain in the left hand with increasing weakness and paresthesia in the left arm. One year later the same symptoms appeared in the right arm and in the right leg. On admission neither pain nor paresthesia was present, but the patient's strength was diminished and his muscles were atrophic. There was an egg sized tumor in the left supraclavicular fossa which could be traced to the left transverse process of the sixth and seventh cervical vertebrae. The sixth cervical intravertebral foramen was enlarged on the left side. The tumor, 9.5 cm. in length and 3.7 cm. in width, was removed in one piece through cervical approach without resort to laminectomy. On microscopic examination the tumor proved to be a typical neurilemmoma. It is suggested that the hour glass tumor gave rise to the symptoms by pressure of its intraspinal prolongation on the ventral part of the cord, the anterior pyramidal tract and the anterior gray horn cells. The removal of the tumor was followed by rapid improvement in the severe paralytic syndrome. This may be explained because of the epidural location of the intraspinal part of the tumor.

Siderosis Bulbi.—A man harbored a chip of iron in his eyeball for eleven years before the appearance of siderosis bulbi. The cornea and muscular tissues of the iris did not contain iron pigment. This was selectively located on the retina in the form of accumulations of free pigment in granulations. The iron in the eyeball was ionizable. Paulo Filho and his associates believe that the first change caused by metallic iron is the partial coagulation of the cytoplasm. Later the newly formed granulations of iron pigment cause necrosis of the retinal cells, with consequent blindness.

Physiopathology and Therapy of Hepatic Cirrhosis.—Yazigi and his associates report observations on 21 patients with hepatic cirrhosis, whom they treated with direct transfusions of the ascitic fluid. They usually began with injections of from 100 to 150 cc. and cautiously increased the quantity until in some cases they had given as much as 1,000 cc. Favorable results usually became manifest rather early. If after five or six transfusions the diuresis does not increase, the treatment will usually result in failure. There were 9 immediate successes and 12 failures. The injections were given every two or three days. Twelve other ascitic patients were treated with blood transfusions. In this group there were 6 immediate successes and 6 failures. The authors were unable to estimate late results in these cases. Both treatments were given without ill effects.

Edema in Surgical Patients.—Efskind reports observations *on 72 patients with different surgical diseases. None of them* presented organic lesions (cardiac, renal, vascular) which might predispose to edema. Sixty-nine of the patients were operated on, and edema was as a rule observed during the postoperative period. The presence of edema was ascertained by finger pressure. Hypoproteinemia is relatively frequent in patients with chronic surgical disorders, since the disorder itself and the operation lead to a drop in the protein content of the blood. Acute hypoproteinemia is usually not associated with edema, even when the protein values are very low. In chronic hypoproteinemia, edema may occur with relatively high protein content. In the author's cases the critical concentration for the occurrence of edema was at about 5.6 per cent total protein; the corresponding concentration in the declining phase was on the average 6.1 per cent. Both these figures are not absolutely fixed values but depend on the length of time the hypoproteinemia and the edema have existed and on their degree of intensity. The absolute limit below which edema invariably appeared was at 4.5 per cent. By converting the protein values into the values for osmotic pressure, the best information as to threatened edema may be provided. In the prophylaxis and treatment of edema in surgical patients the most important primary predisposing factor is hypoproteinemia, which may often be combined with abnormal distribution of fractions. Isolated decrease in the content of albumins seems to be of minor importance. Of the secondary predisposing factors the fluid-salt factor occupies first place. Other secondary factors are the patient's age and general condition, the operative trauma and possible infection. Liver function and its mobile store of proteins are important with respect to the normal regulation of the fluid-salt balance. Protein deficiency is a considerably more important factor than the increased losses in proteins, but a reduced production *also seems to play an important part in the* hypoproteinemia of surgical patients.

Bilateral Acoustic Tumors.—Frykholm reports 6 cases of bilateral acoustic tumors in 3 men and 3 women, 5 of them between the ages of 20 to 28 and the sixth a woman aged 44. All the patients were operated on, 1 of whom died during the operation and 2 others showed no improvement and survived only one to two months. *The 3 remaining patients* were relieved from most of their distressing subjective symptoms and showed improvement in their work capacity. One of them has survived the bilateral intracapsular enucleation of the tumors for more than seventeen years. In the 2 cases in which surgical intervention was performed early, the treatment resulted in definite benefit. Cases of general neurofibromatosis in which the lesions are widely distributed *within the* central and peripheral nervous systems with the severe alterations not due to the acoustic tumors should be excluded from surgical treatment. In all cases a bilateral exposure of the cerebellum should be performed. The dura should not be sutured when the wound is closed unless both tumors have been radically removed. If some hearing function is preserved, the tumor on the side on which loss of hearing is most advanced should be attacked first and its removal performed as radically as possible, preferably with preservation of the facial nerve. The patient will probably not improve completely, but he will certainly be in a better condition *than if he was totally deaf.* The other tumor is not attacked until the general condition begins to deteriorate or loss of hearing is complete. *If improvement is not attained by* the unilateral extirpation and if the patient's condition is desperate, the other tumor may be extirpated in a second session without regard to hearing function but avoiding a bilateral facial paralysis. If the patient is already completely deaf, both tumors should be removed as radically as possible. This can be performed in one or two stages, depending on how well the operation is tolerated. If the facial nerve has been preserved during the removal of one tumor, a radical extirpation may be attempted on the opposite side; otherwise only an intracapsular enucleation is performed.

Case of Leukemic Myelomatosis (Plasma Cell Leukemia). A. Søeborg-Ohlsen and O. P. Nielsen.—p. 271.

Acetylcholine Injections in Normal Persons.—Segers and his co-workers report the results of 250 intravenous injections of 40 persons with 2 per cent acetylcholine solution, most of whom did not suffer with any cardiovascular disorder. The changes in the heart action which are produced in man by the rapid injection of acetylcholine resemble those occurring in animals, but the duration of these changes in man is more brief and consequently they are better tolerated. The slowing of the pulse rate is associated with a considerable fall in the blood pressure. Electrocardiographic recordings demonstrated an inhibition of the superior automatic centers, decrease in amplitude or disappearance of the P wave, lengthening of the auriculoventricular conduction time and in certain cases a shortening of the QT interval, occasionally accompanied by a lowering of the ST segment. The inhibitory effects, whose duration as a rule does not exceed half a minute, may be produced by doses of acetylcholine which vary considerably in different persons. The particular tolerance of each patient must be ascertained with increasing doses of acetylcholine; the injection must be repeated at five minute intervals by adding 0.02 Gm. to the preceding dose. The degree of tolerance of each person can be appreciated by the slowing of the pulse; this tolerance is constant and does not change from day to day. The brief cardioinhibitory phase which occurs as the result of the acetylcholine injection is followed by a phase of quickening of the pulse, which continues for about one minute and during which frequent extrasystoles arise. A brief attack of auricular flutter or of auricular fibrillation occurred in exceptional cases after an injection of more than 0.1 Gm.

Examination of Tongue.—*Frantzell and his associates* carried out a clinical and photographic investigation of tongues from 200 normal persons and 1,300 patients with various diseases in the medical and surgical clinics of the University of Uppsala. A special photographic method for the examination of the tongues was used. The patient presses the tongue against a glass slide so that the surface of the tongue lies in one plane, which is required for a sharp picture. Smooth tongue was the most common pathologic change and was present in 102 patients. An attempt was made to analyze the causes of smooth tongue. It was found that the condition could be attributed to iron deficiency in 27 cases. *Other diseases in which smooth tongue* was comparatively common were pneumonia, decompensated heart disease and malignant tumors. In 31 of the 102 cases no relationship was found between the disease and the smooth tongue. In pernicious anemia a smooth tongue is a common finding, and this condition was noted in 131 patients prior to treatment. In iron deficiency and in pernicious anemia cure of the atrophy of the papillae could nearly always be obtained with specific therapy. Only 14 of 135 cases of pernicious anemia were refractory to liver treatment. In 4 of these iron or yeast caused a rapid improvement. Four cases of paralysis agitans presented a smooth tongue; in 1 of these cases treatment with pyridoxine injections was practiced but proved ineffective. The effect of a dental prosthesis on the surface of the tongue was studied. Fourteen per cent of the men and 47 per cent of the women had an upper prosthesis. The presence of a prosthesis did not materially interfere with the effect of therapy. The prosthesis is not to be considered as the chief causative factor of the atrophy of the papillae, but the possibility that a prosthesis worn for many years may facilitate the appearance of this atrophy must be considered. A proposed hypothesis is that the lingual papillae are sensitive to a lack of oxygen and do not regenerate in the normal way if the oxygen supply is impaired —lack of iron, lack of oxygen, lack of riboflavin or lack of nicotinic acid. If this concept is correct, the surface of the tongue may act as an important index of the degree of hydration of the body and as a mirror of the intracellular oxidative processes.

Liponecrosis of Breast.—Dalsgaard says that in this disease trauma plays a greater part than in cancer of the breast. The boundaries are less well defined and the growth is usually more mobile. Macroscopically the whitish yellow areas are less irregular in form and do not radiate from the center, as is often the case in cancer of the breast. There is not the tendency to concavity of the cut surface or to development of pinkish transparent bands, as in scirrhus. Excision was done in 3 cases of liponecrosis of the breast. The clinical diagnosis was confirmed microscopically. In 1 case, with preceding trauma, there had not been a recurrence after three years. In the second, with processes in both breasts, one of which was removed, recurrence was not seen after five years and the unremoved tumor had disappeared. The third case was not followed up.

Terminal Ileitis.—In the acute cases of terminal ileitis the affected intestine is mobile and exhibits hyperemia and edema. The subchronic processes often develop insidiously without an acute initial stage and resemble ulcerative colitis; there may be a combination of acute and chronic changes. The patients may be treated for various intestinal disorders without permanent effect. The transition from the second or colitis stage to the third or stenotic and the fourth or fistulous stage progresses steadily. Diagnosis may be difficult in the subchronic stage but can be made if the condition is borne in mind. Laparotomy is indicated. Prognosis after radical intervention is good. In chronic stenotic cases resection is indicated, but sometimes a shunting operation must suffice. If fistulas are present, radical operation is called for. Of the 24 cases treated since 1938, 13 were acute and were treated operatively, chiefly on the suspicion of acute appendicitis. Follow-up of 7 patients did not indicate persisting disorder. Of the 7 patients with subchronic ileitis, 5 diagnosed roentgenologically were not operated on because of their age; 2 were operated on during a mild attack diagnosed as acute appendicitis. In 1 of the 3 cases of stenotic ileitis resection of the ileum gave good results; in the second, with ileocecal resection and ileocolostomy, death occurred from operative shock; in the third, side-tracking was done. The last case presented recurring abscesses and fistulas which necessitated ileocecal resection. The abscesses and fistulas persist and the prognosis is doubtful.

Pregnancy in Women Heterozygous with Respect to Diabetes Insipidus.—Forssman studied three families with hereditary diabetes insipidus. Of 25 living women known to him who are heterozygous with regard to the disease, 10 examined to date show an insufficient urine concentration, ascribed to the tendency to diabetes insipidus. In women with this characteristic a pathologic increase in diuresis may appear in the terminal period of pregnancy. The symptoms disappear, though not completely, on delivery, to reappear, usually intensified, in the next pregnancy. After several pregnancies a mild diabetes insipidus becomes chronic. A parallelism is seen between this phenomenon and the change in the anterior lobe of the pituitary during pregnancy. The increased secretion of urine in certain women toward the end of pregnancy is believed to be due to intensification of the diuretic function of the lobe. The genetic defect in compensatory regulation causes the augmentation of the diuresis to appear in increased form in women heterozygous with respect to diabetes insipidus and constitutes diabetes insipidus of pregnancy.

Fantom Experiences in Transverse Lesion of Spinal Cord. B. Cronholm.—p. 319.

Postoperative Gastritis.—According to Christiansen, postoperative gastritis is characterized by polymorphism. There are superficial, hypertrophic, erosive, atrophic or ulcerous elements. The condition develops independently of free hydrochloric acid or the stoma being able to attain rhythmic contraction. If objective improvement occurs, it affects only the erosive and ulcerative elements; the atrophic and hypertrophic changes appear irreversible. Effective therapy is not known. The most helpful treatment is perhaps a combination of ulcer diet and gastric lavage, but subjective improvement is not always accompanied by objective improvement, and in spite of improvement the gastritis may progress. Postoperative gastritis must be considered one of the gravest disorders of the stomach. The various types are illustrated by 9 cases.

Book Notices

All About Feeding Children. By Milton J. E. Senn, M.D., Associate Attending Pediatrician, New York Hospital, New York, and Phyllis Krafft Newill. Cloth. Price, $2.50. Pp. 269. Garden City, New York: Doubleday, Doran & Company, Inc., 1944.

This book contains not all but what the mother needs to know about what to feed children. It is an authoritative manual on the planning and preparation of menus for children from birth to the age of 12 years. The sections on infant feeding and special formula preparation are excellent. The authors take into consideration the varying nutritional requirements of children as they grow. There are welcome suggestions for lunch boxes and party refreshments and meals for children of all ages. Sufficient discussion of nutrition and the properties of the individual foods is included to enable the mother to select her own menus wisely. All of this fine advice is apt to be discredited by the reader because of the obvious ultra conservatism of the authors in advising "if possible" to hold off candy and chocolate milk until the age of 3, malted milk until the fifth year and pickles, radishes, cucumbers and green pepper until the tenth or twelfth year.

The causes and solutions of feeding problems could fill a separate book. The parents of children who present feeding problems require a thorough understanding of what may be involved in order to cope with such problems successfully. It is important that the parents see the feeding problem in relation to the whole personality and environment of the child. Here emphasis is placed too much on mealtime behavior. Since this is supposed to be a comprehensive book, it would be better to omit this important subject entirely than to give it the sketchy treatment it receives.

Miastenia Grave. Por Carlos Virgilio Savoy. Tése de concurso à docência livre de clínica neurologica na Faculdade de medicina da Universidade de S. Paulo. Paper. Pp. 156, with 12 illustrations. São Paulo, 1945.

Since the work of Walker in 1934, when the effects of neostigmine (prostigmine) on the symptoms of myasthenia gravis were reported, there has been growing interest in this disease and considerable research has been undertaken both in the clinic and in the laboratory. The results are now appearing in the medical literature. The book under review is the second monograph on the disease published since 1944. Both emanate from South America. The first, by A. R. Goni, contains histories of 13 cases observed in Buenos Aires from 1937 to 1944. The book by Savoy reports observations on 8 cases observed at São Paulo, Brazil, and, in the form of a thesis, the history of myasthenia gravis is reviewed and recognition taken of the work done particularly since 1934 in the United States and elsewhere. The monograph is a careful and extensive report on our knowledge of the disease up to the present time, and, except for a few omissions, most of the recent investigations are reported. There are illustrations of barium retention in the pharynx, pneumograms showing the effect of neostigmine, ergograms and photographs of a patient with associated and adiposogenital syndrome. The book will be of particular interest to neurologists but should appeal to the medical profession in general, for it deals with a disease now widely recognized and amenable to special supportive treatment with neostigmine and other drugs.

Trauma of the Central Nervous System. Proceedings of the Association December 17 and 18, 1943, New York. Editorial Board: Jefferson Browder, M.D., Chairman, Abraham Max Rabiner, M.D., and Fred A. Mettler, M.D., Ph.D. Research Publications, Association for Research in Nervous and Mental Disease, Volume XXIV. Cloth. Price, $8. Pp. 679, with 243 illustrations. Baltimore: Williams & Wilkins Company, 1945.

This publication contains the proceedings of the Association for Research in Nervous and Mental Disease which took place on Dec. 17-18, 1943. Forty-five investigators or authorities in the fields of neurology, neuropathology, neuropsychiatry or neurosurgery have contributed. There is some overlapping between certain of the chapters, but this is not serious as an equivalent gain results from the expression of the points of view of qualified persons about several borderline problems. This book is a creditable addition to the lengthening list of research publications in nervous and mental disease which have been appearing since 1920.

Das Herz beim Scharlach. Von Privat-Dozent Dr. med. Bernhard Steinmann, Sekundärarzt der Medizinischen Universitätsklinik, Bern. Cloth. Price, 12.80 Swiss francs. Pp. 149, with 21 illustrations. Berne: Hans Huber, 1945.

This monograph is based on clinical, electrocardiographic and radiologic observations on the heart in 350 cases of scarlet fever. The results are analyzed in the light of the literature on cardiac disturbances in scarlet fever and on their relations particularly to rheumatic fever and to focal infections. By means of electrocardiographic studies an early myocarditis without definite clinical signs is separated from a more serious carditis in the second to the fourth week of the attack. This late carditis occurs especially in older children. The intramuscular injection of Dick toxin in rabbits was found to cause disturbances of myocardial function similar to those in early scarlatinal myocarditis. The relations of late myocarditis to different factors and complications are discussed, particularly its similarities to rheumatic carditis. The structural features, the streptococcus etiology and the nosologic relations of the two infections as well as the role of allergy in the genesis of the rheumatic processes are considered. The conclusion is reached that scarlatinal and rheumatic carditis are not identical. The book is an important contribution to the study of the disturbances of the heart in scarlet fever and of related problems.

Annual Review of Biochemistry. James Murray Luck, Editor. James H. C. Smith, Associate Editor. Volume XIV. Cloth. Pp. 856. Stanford University P. O., California: Annual Reviews, Inc., 1945.

This volume is in continuation of an excellent series of reviews which are of valuc in aiding the biologic scientist to keep abreast of rapid changes and advances. The subject matter is presented in chapters on biologic oxidations and reductions; enzymes that hydrolyze the carbon-nitrogen bond; proteinases, peptidases and amidases; nonproteolytic, nonoxidative enzymes; the chemistry of the carbohydrates, of the lipids, of the amino acids and proteins, of the nucleic acids and nucleoproteins, of the steroids, of the hormones, of the triterpenes and of antibiotic substances other than penicillin; x-ray studies on compounds of biochemical interest; the chemistry and metabolism of the compounds of sulfur, of the compounds of phosphorus and of bacteria; carbohydrate, fat and mineral metabolism; the metabolism of proteins and amino acids; nutrition; water soluble vitamins; fat soluble vitamins; animal pigments; detoxication mechanisms; the biochemistry or malignant tissues; nitrogenous constituents of plants; biologic nitrogen fixation, and the mineral nutrition of plants.

How a Baby Grows: A Story in Pictures. By Arnold Gesell, M.D., Director of the Clinic of Child Development, Yale University, New Haven, Conn. Over 800 Photographs Arranged and Interpreted with the Assistance of Katherine Gesell Walden, A.B. Cloth. Price, $2. Pp. 83. New York & London: Harper & Brothers, 1945.

The hundreds of photographs in this book show the growing mind and developing personality of the child as revealed in his early activities. The pictures are uniquely arranged to portray evidences of growth which shape the baby's behavior as he advances. Gradual changes and their portent are clearly demonstrated by interval pictures of the same subject. Each view is so typical that one can match it with a personal recollection. The text is brief but amply explanatory. The author sums up his revelations with principles rather than rules for guidance. His constant plea, reiterated in his closing word to parents, is to treat each child as an individual and to help him develop his own personality and potentialities. Parents will enjoy this book and find it helpful to them in understanding and guiding their children. It shows, more vividly than any written description, when, where and how guidance and discipline should begin.

Quelques vérités premières (ou soi-disant telles) sur la transfusion sanguine. Par Arnault Tzanck et Marcel Bessis. Paper. Price, 80 fr. Pp. 66. Paris: Masson & Cie, 1945.

This is the most recent number in a collection of similar booklets on various topics of medical interest. It covers the practical aspects of blood grouping and transfusion under different conditions. Its distinctive feature is a statement of the essential facts concerning these matters in plain, terse, well worded maxims. The principles and methods appear to be practically the same as ours.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

MULTIPLE SCLEROSIS

To the Editor:—Is there anything new in the treatment of multiple sclerosis? Has any work been done on using penicillin in this condition? A man aged 35, who has been to several clinics, has been diagnosed as having this condition. His illness dates back eleven years. He is now complaining chiefly of the spasticity of the lower extremities, which, as he describes it, causes a feeling of severe pull on the lower spine or back. This is present only when standing; when he is lying down the legs feel free and do not present signs of spasticity and are freely movable. Does climate have any effect on multiple sclerosis? Our New England fall and winter elicit more complaints. I cannot help but feel that our cold and damp weather is bad.

Theodore P. Murphy, M.D., Montpelier, Vt.

Answer.—There would seem to be some reasonable doubt with regard to the diagnosis of the case described. Spastic paralysis of the legs is the most common defect in multiple sclerosis, for impingement of a sclerotic plaque on the corticospinal or pyramidal tracts, extending from the motor cortex to the caudal end of the spinal cord, is almost a certainty, especially if the illness has lasted eleven years. Spasticity, however, is not usually accompanied by "a feeling of severe pull on the lower spine or back" and would never be absent when lying down and present only when standing. Such a change in posture would not affect the deep leg reflexes, which must, in spastic states, be exaggerated, often with the addition of ankle clonus and positive Babinski signs. Without such reflex changes, in part or total, spasticity cannot be shown in the leg muscles. The word "spasticity," moreover, is frequently used loosely, but there is a long standing connotation which limits the use of the word, in describing one type of muscular weakness, to states resulting from a release of the normal inhibition exerted by the corticospinal neuron. Such a condition is due to interference with the impulses passing down this long and important pathway of the central nervous system.

The effect of penicillin on multiple sclerosis is at present undetermined. A few patients may have received it, but reports on its use are not part of the current literature. For a demyelinating disease, such as multiple sclerosis, penicillin treatment would not appear to be effective and, as has often been pointed out, few diseases offer a more hazardous task of therapeutic evaluation than does multiple sclerosis, with its sharp swings from remission to relapse without obvious cause.

Some authors (Freeman) have favored a mild climate for patients with multiple sclerosis. Certainly upper respiratory infections make the disease more difficult to bear. That they actually make the disease worse is less certain. Rest, preferably in bed, during an acute exacerbation is the treatment of choice until some more specific remedy is at hand. Bed rest appears to be often neglected. Vitamins may be added, but their value is uncertain.

Morel has continued the use of magnesium ferriscorbone, a combination of ascorbic acid and iron compound, in the treatment of multiple sclerosis. He reported his initial experiments in 1936, and another report was published in 1942. The treatment is based on the assumption that magnesium may inhibit the destruction of the phospholipids in the myelin and the nucleoproteins in the gray substance. A similar substance with a sodium radical has been used in the treatment of acetonuria in diabetes. Morel gave the drug by intravenous injections. This paper reports observations on 1 case and therefore must be considered as a preliminary report of an unconfirmed form of treatment.

Chavany summarizes the treatment of multiple sclerosis and points out that there is no specific treatment for this disease. The cause is not known; the pathology is not clearly understood; the reason for progression by spontaneous remissions and relapses is not adequately explained. Many drugs are in current use, including the intravenous use of sodium salicylate as advocated by Foix and Levy, mercuric cyanide intravenously, multiple vitamins and the method of fever treatment based on injection of vaccines as advocated by Vincent and Krebs. In each case the results are inconclusive. A combination of fever therapy and vitamins appears to give the best result, but Chavany feels that no form of treatment advocated is sufficiently stabilized to be widely accepted.

Another form of treatment is the use of blood serum obtained from a patient in a stage of remission. Advocated by Laignel-Lavastine and Korressios in 1938, it has been repeatedly tried since that date. In the hands of Carballo and his associates in Madrid the results were equivocal.

Benedek and Horanyi-Hechst treated a severe case of multiple sclerosis in which many symptoms had existed for at least five years, including transient attacks of blindness, urinary incontinence, speech difficulty and particularly pathologic laughing. Twenty-five cc. of air instilled into the ventricles resulted in immediate relief of laughing which lasted for a two months period of observation. On theoretical grounds it was felt that the instillation of air changed the vascular supply of the hypothalamic structures surrounding the third ventricle, the presumed site of pathologic laughing in association with the cortex, thalamus and brain stem.

ASPHYXIA OF THE NEWBORN

To the Editor:—How is carbon dioxide or plain oxygen used in asphyxia of the newborn? What is the value of nikethamide and other stimulants? Our interns come from various schools with ideas as to what to do and feel that we are old fashioned in using carbon dioxide when the babies are already cyanotic.

M.D., Kansas.

Answer.—The treatment of asphyxia of the newborn, in the absence of anemia, should have three objectives. The first objective is to make certain that the airway is not obstructed. The second objective is to oxygenate the blood in order to support the heart and to prevent anoxic injury of the cells of the cerebral cortex. The third objective is to initiate spontaneous and adequate respiratory movements. The more quickly the first two objectives are attained by any harmless method, the better for the patient. If the blood can be kept oxygenated by artificial means, the initiation of spontaneous and adequate respiratory movements is of secondary importance from the point of view of the most immediate vital need, namely oxygenated blood.

What are the reasons for mixing carbon dioxide with oxygen for the treatment of asphyxia? First, carbon dioxide is a respiratory stimulant: this is agreed to by every one. Pronounced anoxia depresses the respiratory center, and hence it is argued that carbon dioxide should be used to stimulate the depressed respiratory center. Second, carbon dioxide increases the depth of inspiration and relieves or tends to relieve atelectasis and to prevent the development of pneumonia. The entrance of air or gas into the pulmonary alveoli of the newborn changes the epithelium from a cylindric to a flattened form. It would appear that several deep inspirations would open more alveoli and flatten their epithelium than many shallow inspirations. It has not been established, however, that a deep inspiration excited by the inhalation of carbon dioxide is more effective and less harmful potentially than mechanical insufflation with 100 per cent oxygen. Third, carbon dioxide is claimed to increase venous return to the right side of the heart by increasing venopressor tone and thus to improve the circulation. This claim has not been established, though a deep inspiration does favor venous return. On the contrary, it has been claimed that in anoxemia due to obstruction and depression of the respiratory center there is already an excess of carbon dioxide in the blood and tissues and that the addition of more is irrational and likely to produce injury and "overstrain" the heart. This claim has not been clearly established. Fourth, carbon dioxide in oxygen increases the rate of dissociation of carbon monoxide from hemoglobin in carbon monoxide asphyxia. This is quite well established. Whether 7 per cent carbogen (7 per cent carbon dioxide plus 93 per cent oxygen) is superior to 100 per cent oxygen in regard to the end results (survivals and neurologic sequelae) of the treatment of carbon monoxide asphyxia is at present debatable.

Thus there is no argument regarding the advisability of the use of 100 per cent oxygen in asphyxia neonatorum. It should be used with manual or mechanical artificial respiration. If the blood becomes red the primary objective has been attained; then the condition of the respiratory center can be considered. If 100 per cent oxygen is given by endotracheal intubation under intermittent pressure and the blood does not become red, a venoarterial shunt or massive pneumonia is present. If after the blood has been fully oxygenated for several minutes respiration does not occur spontaneously when artificial respiration is stopped and cyanosis recurs, then the presence of cerebral trauma or deep anesthesia of the respiratory center should be suspected. Excessive carbon dioxide is removed from the blood and tissues after complete oxygenation of the blood has been maintained for five or ten minutes. At this point 5 or 7 per cent carbogen can be administered for a minute or two. If this procedure is followed, all of the criticisms previously mentioned can be avoided except the report that carbon dioxide in oxygen increases intracranial pressure (W. F. Von Oettingen, Public Health Bull. 290).

The differences of opinion in the obstetric services in our sixty-three medical schools regarding the use of carbon dioxide and stimulants in asphyxia neonatorum have been summarized by Dr. P. J. Flagg in his book "The Art of Resuscitation" (New York, Reinhold Publishing Corporation, 1944). Ten of the sixty-three voiced objection to the use of carbon dioxide; the remainder either approved or did not voice objection. Of fourteen services which wrote of their experience with drugs, nine were favorable and five were unfavorable to the use of alpha lobeline or nikethamide.

NERVE CRUSHING PROCEDURE FOR POLIOMYELITIS

To the Editor:—The Department of Health, Troy, Ohio, recently received an inquiry concerning the Billig-van Harreveld procedure for treatment of residual paralysis from poliomyelitis. Our department, as well as our local chapter of the National Foundation for Infantile Paralysis, would like the following information: 1. What does this treatment consist of, and how effective is it? 2. Is it an ethical and recognized procedure? 3. Is the institution offering it an ethical, reputable and recognized institution? 4. Would we be justified in referring cases to this institution and recommending payment for this type of treatment from our local poliomyelitis foundation?

Harry Wain, M.D., Troy, Ohio.

ANSWER.—1. The Billig-van Harreveld procedure consists of a manual operation to interrupt the remaining intact motor nerve fibers of a paretic muscle. Its success supposedly depends on the tendency of such nerves to branch during regeneration, thereby providing an increase in the number of nerve fibrils available for muscle cells. The operative procedure is followed by intensive physical therapy and muscle reeducation. The procedure is commonly known as the "nerve crushing" operation. There is of course no assurance that improvement will result and no way of anticipating to what extent such improvement as does occur may develop. The reported results in over 800 cases appear to be hopeful.

2 and 3. This procedure is still in the experimental stage. It is carried out by well recognized, qualified surgeons at the St. Luke's and Children's Medical Center, Philadelphia, in cooperation with the University of Pennsylvania Department of Physical Medicine. These institutions are, of course, ethical, reputable and of high medical standing.

4. Since this procedure is carried out by duly licensed physicians in accredited hospitals there is no reason why cases should not be referred for the treatment. The local chapter of the National Foundation for Infantile Paralysis should determine through its own advisers the method of payment.

HISTAMINE FOR MIGRAINE

To the Editor:—I am anxious to obtain some information on the use of histamine in the treatment of migraine, with detailed method of use.

George B. Ribble, Comdr. (MC), Glenview, Ill.

ANSWER.—A specific cure for migraine has not yet been announced. There is evidence to indicate that histamine may be of value in alleviating the syndrome to some extent for variable periods of time. Not all patients who have migraine respond to histamine, and, of those who do, not all derive the same degree of benefit. It would appear as if the effect of histamine on the migrainous mechanism is a relatively transient one. It is of little or no value in aborting acute episodes of migraine, and it is used chiefly with the idea of preventing further attacks.

Histamine can be administered in desensitizing doses by the subcutaneous route or by the intravenous route. A combination of the two procedures seems more effective in preventing future attacks than does either procedure when carried out alone.

More work will have to be done in this field before definite conclusions can be drawn with reference to histamine in the treatment of migraine.

The nervous tension state is often so intermingled with the migraine problem that it is difficult to determine whether one is dealing with migraine per se or not. Consequently it is not easy to evaluate a therapeutic agent which is used with the idea either of aborting acute attacks or of preventing future attacks.

The following is a partial list of publications referring to the treatment of migraine with histamine:

Butler, Stuyvesant, and Thomas, W. A.: Intravenous Histamine in the Treatment of Migraine: Preliminary Observations, THE JOURNAL, May 19, 1945, p. 173.

Horton, B. T.: Symposium: Head and Face Pain; Medicine, *Tr. Am. Acad. Ophth.* **49**: 23 (Sept.-Oct.) 1944.

Levin, I. A.: Migraine and Histamine Headaches, *J. Louisiana State Univ. School Med.* **3**: 10 (Aug.) 1942.

Lieder, L. E.: Histaminic Cephalalgia and Migraine, *Ann. Int. Med.* **20**: 752 (May) 1944.

PSEUDOTUBERCULOSIS IN LABORATORY ANIMALS

To the Editor:—Some of my guinea pigs are dying from a condition which is generally called pseudotuberculosis. How can I get rid of this epidemic without destroying all the animals and starting with new animals after a thorough disinfection?

Stephan Epstein, M.D., Marshfield, Wis.

ANSWER.—Pseudotuberculosis is a widespread infectious disease of rabbits and guinea pigs caused by a gram negative, nonmotile, short or coccoid form of bacillus belonging to the hemorrhagic septicemia group. The micro-organism is most often referred to as Bacillus pseudotuberculosis rodentium of Pfeiffer or of Nocard and Preisz. The bacillus is readily stained by aniline dyes and its body often takes up the stain unequally. Serologically it resembles Pasteurella pestis most closely, from which it is often differentiated with difficulty. Cows, horses, monkeys and even man also may be affected. The bacteria are widespread in nature and are encountered in the soil and elsewhere. They are usually saprophytic and only under certain unknown conditions of the host do they become pathogenic. The natural mode of infection is by way of the alimentary tract, as evidenced by the common occurrence of lesions in the intestine and the mesenteric lymph nodes. Affected animals eliminate the bacteria in the feces, and animals can be artificially infected by ingestion. The disease is characterized by the appearance of numerous yellowish nodules in various organs. The appendix and ileocecal junction of rabbits are a frequent site of localization. The mesenteric nodes, the liver and the spleen are often affected. The lung is less often involved. Histologically the lesions consist of circumscribed nodules of mononuclears intermixed with a great many polymorphonuclears. The center of the lesion usually is occupied by necrotic cells and nuclear débris. On the periphery of the nodule there is a considerable proliferation of granulation tissue. The center of such encapsulated lesions is often transformed into a thin pus, where the bacilli may be found in small clumps. Epithelioid and giant cells are rare, and in this respect the lesions differ most sharply from those of true tuberculosis; nor is calcification encountered in pseudotuberculosis. Agglutinins appear in infected animals. Recently Ramon has obtained a toxin from this bacillus which is lethal to rabbits. He has also prepared a toxoid. He demonstrated that animals immunized with this toxoid or with solution of formaldehyde and heat-treated bacteria, by repeated subcutaneous inoculation, can be protected against virulent bacteria fatal for normal rabbits. There is as yet no confirmation of Ramon's studies.

For the present, the prevention of the disease must depend chiefly on prophylaxis. It is most important that animals be protected from contact with their own feces. This may be achieved by frequent sterilization of the cages with hot steam, the installation of wire mesh bottoms in the cages where the animals are housed and the provision of drinking bottles so arranged that the water cannot become contaminated by the excreta of the animals. These hygienic measures, together with the maintenance of an adequate diet, will largely eliminate the infection.

SUFFOCATION AND BLOOD CARBON MONOXIDE

To the Editor:—To the query about "Suffocation and Blood Carbon Monoxide" (The Journal, Dec. 29, 1945, p. 1295) I would like to add the following: It is known that carbon monoxide hemoglobin can be found in exhumed bodies. I reported a case in which I could discover carbon monoxide hemoglobin in the bloody transudate which was present in the chest cavity of a man who had died from acute carbon monoxide poisoning, three months after his death. The body had not been embalmed, however. The case is reported as "Beobachtungen bei Exhumierungen" (observations at exhumations) in the *Aerztliche Sachverständigen-Zeitung* 34: 241 (Aug. 15) 1928. This [illegible] and similar ones prove that carbon monoxide hemoglobin disappears slowly from the body, probably only when the blood and tissues are destroyed by advanced putrefaction and decomposi[illegible]
